New Issues.—The North Wales Power and Traction Company are making an issue of 50,600 shares of £5 each. From the prospectus, which appears in another column, it will be seen that the scheme on which the company is based comprises the generation of electrical energy at a low cost by means of water power from lakes on Snowdon and in the neighbourhood of Conway, without steam power and the expense of coal. The current will be supplied to a short railway, subsequently referred to, which is to be extended and electrified; to certain towns in the district of Snowdon, to local quarry owners, and in bulk to more distant consumers. Under the Portmadoc, Beddgelert, and South Snowdon Railway Act, 1901, the Portmadoc Company was incorporated by the name of the Portmadoc, Beddgelert, and South Snowdon Railway Company, with an authorised share capital of £270,000, and with borrowing powers. One of the objects of this company is to acquire by subscription the whole of the capital that it may be found necessary to issue of the Portmadoc Company, which will own and operate the Portmadoc undertaking. Under the Act, the Portmadoc Company may abstract, impound, appropriate, and use the waters of Lake Lyldaw and Lake Teyrn, and develop power by means thereof. The directors anticipate that the whole of the power not required for the railway and lighting purposes will be readily disposed of for use locally. The area of supply under the Act is the parishes of Beddgelert, Criccieth, and Ynyscynhaiarn (Portmadoc), but it is expected that the cheap rates at which the company will be able to supply energy in bulk will induce railway companies and other large consumers at a distance to take steps to connect with the company's system. Subscriptions for 35,500 shares, which is the minimum subscription, having been guaranteed, the lists will close for town and country to-day.—The Consolidated Electrical Company, Limited, are making an issue of 15,000 cumulative 6 per cent. preference shares of £1 each. This company was formed on April 16, 1903, and is a reconstruction of the Consolidated Telephone Construction and Manufacturing Company, Limited, whose business was taken over as a going concern. The authorised capital is £125,000 in shares of £1 each, of which 109,096 have been issued as ordinary shares, and 904 ordinary shares are held in reserve for future issue. The object of the reconstruction was to provide the undertaking with working capital for the development of its manufacturing business, which is of a high-class character, and mainly with the General Post Office, the Admiralty, the War Office, and other Government departments, railway companies, telephone companies, and municipal authorities. The reconstruction gave the company an initial cash capital (subject to payment of preliminary and legal expenses, underwriting, etc.) of about £28,000, of which about £16,000 is still uncalled. According to the prospectus, which appears in another column, the net profits of the old company for the last three years, as per the published accounts audited by Messrs. Deloitte, Dever, Griffiths, and Co., after deducting administration and all other charges, debenture interest, etc., were: 1900, £2,982; 1901, £2,474; and 1902, £2,497. Hitherto the dividend on the Anglo-Portuguese Company's shares has been restricted to 3 per cent., about £40,000 of profits having been appropriated to capital purposes. The need for a continuance of this policy no longer exists, and future dividends should therefore be at a higher

Digitized by Google

rate, the surplus net earnings being equal to more than 10 per cent. on the share capital. A dividend of 10 per cent. on the Anglo-Portuguese shares would give the new company an additional net income of nearly £2,000 per annum. A trading profit of only 10 per cent. on the new capital brought into the new company as the result of the reconstruction, etc., would further increase the income by about £2,500 per annum. These two additional sources of income, added to the profits above mentioned, would give a total net income of from £5,000 to £7,000 per annum, on which the preference dividend of £900 per annum would be a first charge.

PROVISIONAL PATENTS, 1903.

JULY 23.

16232. Improvements in the manufacture of electrical resistances. Thomas Edgar Weaver, 134, Claremont-road, Moss Side, Manchester.

16258. Improvements in rotors for electrical machines. Alfred George Brooks, 55, Chancery-lane, London. (Electricitäts-Gesellschaft Alioth, Switzerland.) (Complete specification.)

16294. Improvements in electric arc lamps. Heinrich Beck, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16300. A coupling for wires, cables, and the like adapted for use both for mechanical and electrical purposes. James Ernest Spagnoletti, 53, Chancery-lane, London.

JULY 24.

16348. Improvements in electrical stop motion mechanism for textile machinery. Joseph Botsford Whitney, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16360. Improvements in means for breaking electric circuits. Carl Bennett Auel and John Rudolph Spurrier, Westinghouse-building, Norfolk-street, Strand, London.

JULY 25.

16388. An improved tumbler switch for electrical purposes. Veritys, Limited, and Daniel Evan Rogers, Victoria Works, Plume-street, Aston.

16425. Improvements in telephone exchange systems. William Aitken, Milton-road, Edge-lane, Liverpool.

16440. Signalling apparatus worked by alternating currents. Siemens Bros. and Co., Limited, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktiengesellschaft, Germany.) Complete specification.)

16454. Improvements in shuttles and electrical mechanism for indicating approaching failure of weft in looms for weaving. José Reixach and Herbert Scott, 24, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published August 20, 1903.

1902.

16419. Shuttles used in weaving for electrically changing the shuttle before the weft has become completely exhausted. Davidson.

16439. Application of electric motors for automobile vehicles. Sefton-Jones. (Cantono.)

16529. Apparatus for reducing attenuation of electrical waves in conductors or cables. Pupin. (Date applied for under International Convention, Dec. 14, 1901.)

16550. Controlling alternating electric currents for signalling. Thompson.

16664. Trolley heads or collectors for electrically-propelled vehicles. Mercier.

16695. Prepayment or coin-controlled electric meters. Harrison and Bastian.

16904. Regulating devices for dynamo-electric machines. Lake. (General Electric Company.)

16927. Starting devices for induction and other electric motors. Lake. (General Electric Company.)

17300. Clamps for trolley wires. Lake. (General Electric Company.)

17630. Electric arc lamps. Lake. (General Electric Company.)

18066. Charging devices for electromobiles. British Thomson-Houston Company, Limited. (Cox.)

18068. Electric transformers. British Thomson-Houston Company, Limited. (Everest.)

18317. Electric motor control systems. British Thomson-Houston Company, Limited. (Mundy.)

18318. Electric transformers. British Thomson-Houston Company, Limited. (Moody.)

18319. Electric switches and cut-outs. British Thomson-Houston Company, Limited. (Badeau.)

18321. Electric motor control systems. British Thomson-Houston Company, Limited. (Case.)

18632. System of control for multiple-unit electric trains. Von Zweigbergk.

20886. Automatic lifeguard to be attached to electric cars. Palmer.

20931. Automatic electric fire-alarms and generally applicable to heat-operated signalling and controlling devices. Venner.

22233. Electric heating apparatus. De Mare.

22551. Electrical signalling system for railways. Mills and Piddington.

23461. Magnetic apparatus for the distribution of current to electric tramways and railways by road contact. Mills. (Diatto.)

1903.

2393. Electric power systems, especially applicable to railway and tramway vehicles. Thorn

6546. Electrically-operated railway switches and signals. Neelemans.

7713. Electric switching arrangements. Evans. (Allgemeine Electricitäts-Gesellschaft.)

9576. Telephonic apparatus. Wood.

10298. Secondary or storage batteries. Lake (Darling and Chronik.)

11125. Brush-holders for dynamo-electric machines and electric motors. Johnson-Lundell Electric Traction Company, Limited. (Lundell.)

11826. Electric driving mechanism for centrifugal machines. Evans. (Allgemeine Electricitaets-Gesellschaft.)

14558. Electromagnets. Lindquist.

14575. Holders for electric incandescent lamps. Kleber.

NOTES.

Junior Institution of Engineers.—We would remind our readers that the summer meeting of the above institution is to be held at Sheffield, commencing on Monday, Aug. 17, and concluding on Saturday, Aug. 22. The first day's proceedings will be opened at the town hall at 11 a.m., when the Lord Mayor will welcome the members to Sheffield.

The London Traffic Commission.—We are pleased to hear that the members of the Royal Commission on the London traffic continue to inspect the points of worst condensation in our public streets. They are aided in so doing by the Automobile Club, who place motors at their disposal. We believe that these rides through London have convinced the Commission that the traffic is much impeded by electric lamps placed in the middle of the road over refuges, as in Piccadilly.

British Association.—We would remind our readers that the British Association meeting is to be held at Southport, commencing on Sept. 9, with Sir Norman Lockyer as president. The meeting this year is likely to prove of exceptional interest, for the annual International Meteorological Congress is to be held at Southport at the same time, so that a large number of distinguished foreign scientists are likely to attend the meetings of the British Association.

Tunbridge Wells Telephones.—At the last meeting of the Council it was urged that the National Telephone Company had infringed the terms of the agreement made with old subscribers when they took over the municipal undertaking. In this agreement unlimited service for £6 per year was promised. The company are now demanding 5s. extra as stamp duty. The town clerk is to look into the matter. In the course of the debate it was said that the service had become much less efficient since the transfer. This is naturally to be expected as a consequence of the removal of competition.

Science Research Scholarships.—The Royal Commissioners for the 1851 Exhibition have made 15 awards this year for science research scholarships of £150 per annum. These are held, as a rule, for two years, subject to a satisfactory report of progress after the first year. The recipients hail from 12 of the principal colleges in the provinces and one in London. We are glad to see that the remaining two scholarships go respectively to students at the McGill University, Montreal, and the University of Sydney. The Commissioners have continued for a second year 15 scholarships granted in 1902, while six granted in 1901 have, for exceptional reasons, been renewed for a third year.

The Heligoland Lighthouse.—Germany is remarkably proud of the success of the new electric flashlight which has been erected on the island of Heligoland. It will be remembered that this island was transferred by us to Germany some years ago. Thus, with a view of supporting home industries, the new lighthouse equipment is entirely of German manufacture. It is claimed that it is fully equal to the best French revolving light. The apparatus consists of a revolving parabolic reflector made by the Schuckert Company, which is said to give 30 million candle-power. The flashes are a tenth of a second in duration, and succeed each other every five seconds. The light has been observed at a distance of 40 miles.

Heavy Electric Locomotive.—There has recently been turned out at the works of the General Electric Company in America what is stated to be the largest and most powerful electric locomotive yet built. It weighs 180 tons, and is designed to haul a freight train of 1,500 tons up a grade of 1½ per cent. The capacity of the motors is 2,000 h.p. The locomotive is made up of two units, each weighing 80 tons, and is so arranged that any number of units may be coupled together, making it as much larger as is desired. All the units are controlled from the one place. There are eight 42in. driving wheels on each unit, making 16 driving wheels on the locomotive. It is to be used in the tunnel of the Baltimore and Ohio Railway at Baltimore.

Value of the Ampere.—According to an American exchange, four professors of the University of Michigan have made arrangements to determine the exact value of the ampere. If the experiment be successful, the Government will be asked to change the present law stating the value of the ampere, which is the amount of current that will deposit 1·118 milligrammes of silver a second from a specifically prepared solution of silver nitrate. This is the law also in European countries and is slightly in error. Scientists have several times attempted to correct the last figure. The Michigan professors have constructed an absolute dynamometer which is not affected by heat, cold, moisture, or gravitation. No instrument quite similar has, it is said, ever been used before.

St. Louis Electrical Congress.—The International Electrical Congress in connection with the Universal Exhibition at St. Louis next year has been fixed for the second week in September. The congress will last from the 12th to the 17th, and will meet under the presidency of Prof. Elihu Thomson. It is proposed to divide up the congress into eight sections, the first of which will deal with general theory, both mathematical and experimental. The other seven sections will have to do respectively with general applications, electrochemistry, electric power transmission, electric light and distribution, electric transportation, electric communication, and electrotherapeutics. It is hoped that all the electrical associations and institutions of the States will meet at St. Louis during that week. All communications respecting the congress should be addressed to the general secretary, Dr. A. E. Kennelly, at the Harvard University, Mass.

Mediæval Opposition.—Truly extraordinary is a story of the failure of an attempt to establish a telephone service at Saint-Etienne des Gres, situated in the Tarascon district. The necessary apparatus had been packed all ready to start for the village when the carter heard that the inhabitants, being under the odd impression that the invention was the work of the Evil One, were determined to oppose its entry, and were resolved to arm themselves with their agricultural implements, and to make a fight of it. The man said that he was willing to confide his cart and its contents to the electricians, but that as for himself he would not risk his life in such an adventure. A telegram was forwarded to Marseilles asking for instructions, and the reply came that the cart was to be left at Tarascon What the sequel to the present deadlock will be remains to be seen, but meanwhile the good people of Saint-Etienne des Gres stoutly declare that they will have nothing to do with the telephone, which is "a diabolical machine."

Niagara Cable Conduit.—It will be remembered that in January last the whole of the Niagara Falls works were shut down by the burning of the cables which connected the two portions of the generating station. These were carried over a covered bridge, which served to concentrate the fire and to render it inaccessible. In order to replace these mains, a cable conduit 805ft. long was built over the canal, having 24 ducts. This was

Digitized by Google

erected at once to enable the supply to be resumed. A new conduit is now being constructed, which will have 60 3½in. openings. These ducts are to be laid in groups of 12, with just sufficient concrete to hold them in place. This construction has been adopted to get as much ventilation as possible, so as to get rid of the heat due to ohmic loss in the copper. The ducts will also be ventilated by means of openings into a walk which is laid over and a little above the conduit. When this work is completed the old bridge will be taken down.

Platinum.—The report of the United States Geological Survey for the past year shows that the production of platinum from ores found in that country has decreased enormously during the year. In 1901 1,408oz. were produced as against only 94oz. in 1902. Platinum in the United States in recent years has only been obtained as a secondary product chiefly from gold placer deposits in Trinity and Shasta Counties, California. It is reported that the metal occurs, though not in commercially rich deposits, in many other gold placers of California, as well as in Washington, Oregon, Idaho, Montana, Colorado, and Alaska. The Rambler Mine, Wyoming, continues to attract attention, and during the year a considerable quantity of the metal was collected, but not marketed, by the Waratah Minerals Company at Kerby, near Grants Pass, Josephine County, Oregon. It would seem from the above that there is not much chance of the price of platinum being reduced by an increased output in America.

City of London Electric Contracts.—The final appeal in the long-drawn-out case between the City of London Electric Lighting Company, Limited, and the Mayor, Commonalty, and Citizens of the City of London was concluded in the House of Lords on Aug. 8. The result was that the decision of the lower Court stands, which condemns as unsound two of the agreements between the company and the Corporation, and confirms the third agreement, which was originally made between the Laing, Wharton, and Down Construction Syndicate and the Commissioners of Sewers. We have gone into this question so frequently that there is hardly need to again refer to the matters in dispute. We would conclude by saying that, however legal the result may be, it does not conduce to the credit of the Corporation of London. We should rather have expected a body with the reputation which this Corporation holds to stand by its contracts on which the public have expended money, even if these contracts were invalidated by a legal quibble. The only logical conclusion of the present case is that all prominent men within the city of London who are, or who are likely to become, common councillors, should be debarred from holding any shares in any limited liability company having the city of London in its sphere of operation.

Electrical Protection of Safe Deposits.—The protection of the safe deposits in the United States Treasury Department is by electrical means, the aim and effect of which are to guarantee that if any attempt is made to enter the strong rooms where the deposits are kept an alarm shall immediately be given. The vaults themselves are lined with hardwood, tightly joined at every corner. Inside this lining is laid a thin coat of tinfoil, and on the tinfoil is placed a fine netting or screen of wires, every wire of which is carefully joined and highly polished. Over this screen of wire mesh another lining of hardwood is placed. The wires run continuously in every strand, from the floor up the side, and join corresponding wires at the ceiling of the vault. At a point on top there is a feed wire, which connects with the wires of the netting and forms a complete circuit. This feed wire is run from the vault to the central station, which generates alternating current. Three times every five minutes it is varied, so that no succeeding five minutes will correspond to another five minutes. A contrivance is placed at the top of the vault which will automatically give notification at the central station if the electrical apparatus fails to work, or if the currents fail to charge all the wires. Thus, if the walls, ceiling, or floor of the vaults are tampered with, an alarm is rung at the station.

Selenium Cells. — Prof. Ruhmer's photo-electric selenium cells have been given the benefit of prolonged trial and experiment in the German navy in connection with light telephony. In the method adopted a beam of light projected by a parabolic reflector falls on another reflector connected with selenium cells and a telephone. Changes in the intensity of the beam of light can be effected at the sending station by superimposing on the electric light current the current through the telephone of the speaking station. This is sufficient to indicate the general principle of the method. These variations in light are recorded by the selenium cell at the receiving station, and are reproduced again as electric differences through the receiving telephone. The success of such experiments, however, depends on the trustworthiness of the selenium cells. That is by no means a fixed quantity, and the method is still a laboratory rather than a commercial success. A more novel use of selenium cells, and one which is very appropriate to their name, has lately been made by Prof. Ruhmer, who employs the cells to record an eclipse of the moon. The rays of the moon are reflected by a parabolic mirror on to the selenium cell, and the variations of the light as the moon enters the shadow of the earth and emerges again are all accurately recorded by the differences of intensity of the electric current as it passes through the selenium cell and the cell's resistance alters.

Pacific Cable Finances.—The further information which we give with regard to the finances of the "all-red" Pacific Cable may profitably be read in conjunction with that published in our last issue under this heading. Sir M. Hicks-Beach raised the subject in the House of Commons on Thursday, the 6th inst., asking the Chancellor of the Exchequer what is the total amount charged to the Exchequer up to March 31, 1903, in respect of interest, sinking fund, and working expenses of the Pacific Cable; how much of that amount is due from the Colonies which undertake to share the cost of the cable; and when this latter sum will be received. Mr. Ritchie, in his reply, said the audit of the Pacific Cable Board's accounts to March 31, 1903, had just been completed. The accounts have not yet been formally transmitted to the Treasury, but he has ascertained that they show a total net expenditure charged to the Exchequer grant up to March 31 last of £91,437. 4s. 11d. This charge covers interest and also the working expenses of the cable so far as they exceeded the traffic receipts. It includes nothing for the sinking fund, as the first instalment of the annuity for repayment of the money borrowed for construction does not become payable till December next. The share due from the contributing colonies in respect of the expenditure to March 31 last is £65,374. 5s. 4d., and payment will be claimed from the Colonies as soon as the Board's accounts are received.

Foreign Tramrails. — The recent action of the London County Council and some other municipal bodies in the country in accepting tenders for Belgian rails for electric tramways in preference to English rails, probably prompted the following question which Mr. Randles put to the President of the Board of Trade in the House of Commons on Thursday last week. He invited the Presi-

Digitized by Google

dent to state what proportion of the tramrails laid in the United Kingdom during the last 10 years were of British manufacture, and what proportion of Continental manufacture, and would he also give the same particulars as to the tramrails laid in the metropolitan area in particular. Mr. Gerald Balfour said the Board of Trade had no information which would enable him to answer the first portion of the hon. member's question. With regard to the second paragraph, he had communicated with the London County Council, and they informed him that in connection with the reconstruction for electrical traction of their tramways about 5,000 tons of rails of British manufacture and 10,720 tons of rails of foreign manufacture have been purchased by the Council. Previously to the transfer the company used about 1,000 tons per annum of foreign rails and none of British manufacture. They add that they have no information as to the rails used by the North Metropolitan Tramways Company—the lessees of the Council's northern tramways — nor as to what is done by other tramway companies in London.

Institution Building Scheme.—As the outcome of the special meeting of Electrical Engineers which has been recently held, it is decided to purchase some ground for the Institution, so that we shall before many years have a building in which to hold the usual meetings. The site which has been acquired in Tothill-street is in a good position, and it is quite likely that a scheme can be devised which will enable certain portions of the building to be erected to be let at remunerative rates. The only question with which we are concerned at present, however, is that the Council should see to it that the acquisition of the site and the financial engagements which they would have to enter into in developing the same and in building shall not hamper the normal work of the Institution. If the scheme involves increased subscriptions to the younger members of the Institution, it cannot be too strongly condemned. It must be remembered that there is no electric lighting station in the kingdom which has such a bad load factor as an institution building. The number of hours per year when the lecture theatre is in use are few, and, unfortunately, the same may be said of the library. We do not mean that the library is not open to members, but that so few members make use of the convenience which the collection of books affords. The building may be said to be one for the honour of the profession, but this honour will not be advanced if heavy subscription rates prevent young men from joining the Institution.

New York Sunday Papers.—We know that all the best, most striking, and most far-reaching advancements in science first see the light in the columns of the New York Sunday papers. Out of a recent issue we notice two important scientific notices, to the first of which, however, the above can hardly be attributed. The interview in question is one with Mr. Barringer Cox, on the production of electricity direct from coal. The technical information given in this fits in with the details of the thermo-electric device which Mr. Cox exploited some years ago from St. Albans, the output of which was measured by multiplying the current on short-circuit into the voltage on open circuit and then applying a constant, which we could never obtain from the inventor. The second invention is one which is distinctly new. It is claimed for and by a Mr. Rudolf M. Hunter, of Philadelphia, that he has solved the problem of the alchemist, and will soon begin to manufacture gold on a large scale. This philanthropic inventor debated within himself for a long time as to whether he should keep his invention to himself, or rather the profits of his invention. He has decided, however, after many heart searchings, to accept £100,000 for working capital from outsiders. The lucky individuals who advance this are to receive no less than 57,000 per cent. per annum. We should not be surprised, however, to hear that Mr. Rudolf M. Hunter finds difficulty in raising his capital in the present depressed state of the money market.

Wireless Telegraphy in Naval Manœuvres.—The special correspondent of the *Standard*, in the issue of that paper for Aug. 10, gives a fair description of how wireless telegraphy systems interfere in practice. He says, "I have mentioned that our cruisers joined us on the Wednesday, and it was about noon on that day that we were able to establish wireless communication with the 'Europa,' the only first-class cruiser that is attached to the 'B 2' command. We were in communication with her, it was true, but continued interruption from the Marconi station at the Scillies prevented our getting much sense out of her messages—this the more aggravating as all we could make out was the startling announcement, 'Have collided with steamship "Rupert," 14 miles—' and then an abrupt termination. However, an hour and a half later a message from the Scillies was passed through to us by the 'Europa,' which ran: 'Melampus' collided at 3.15 a.m. with s.s. "Rupert," 14 miles S. ½ E. of St. Agnes Lighthouse. All hands saved. Damage "Melampus" being heavy, captain of "Europa" ordered her into Devonport with saved crew.' From this we deduced that the 'Melampus' had sent something to the bottom, and that for the forthcoming manœuvres, unless a new ship takes her place, Admiral Wilson's fleet is one second-class cruiser short. The method of our getting the news is illustrative as showing how very easily wireless telegraphy can be fogged, and how, at present at any rate, its utility is more or less of an uncertain character." Further comment is not needed.

Electric Automatic River Gauge.—In America the gauging of a river automatically by electrical means is being accomplished with considerable success. The apparatus is the invention of Prof. W. M. Fulton. It consists of two parts. One, the gauge, is located at the Tennessee River, and the other, called the recorder, is placed in the Chattanooga weather bureau station. The former consists of a large and a small pulley mounted upon the same shaft. A separate wire is wound around each pulley, one carrying a float and the other a counterbalancing weight. Connected to the shaft is a train of gears, so designed that a second shaft is given one complete revolution to a rise or fall of one-tenth of a foot in the float. In order that the weight and float shall always rise and fall in the same plane, as the wires are wound on the pulleys, the first-mentioned shaft has screw journals, which give the shaft a lateral motion, keeping the wires in the same vertical plane. The recording apparatus consists of a drum wound with a recording sheet, and is moved laterally by a screw shaft operated by pawls and ratchets. The pawls are so constructed that they act in a manner similar to a clock escapement, and thus the ratchets can be moved only one tooth at a time. The drum is revolved by clockwork. Connection between the recording mechanism and the gauge is electrical. When the second-mentioned shaft of the gauge makes one complete revolution in one direction, an electrical contact is made and an electromagnet at the recording apparatus operates one of the pawls, and the ratchet connected to it moves the pencil along the drum, which is at the same time revolving. If the float moves in the opposite direction another electrical contact is made, and the other set of pawls and ratchets move the pencil in the opposite direction along the drum. Thus a complete graphical record is obtained of every $\frac{1}{10}$ft. rise and fall of the stream.

Profit-Sharing for Telephone Employes.—The *Electrical World* of New York gives the full text of a circular which Mr. F. S. Bickson, the president of the Cuyuhoga Telephone Company, of Cleveland, has just issued to the employés of the company. We extract from this the following particulars. Mr. Bickson tells his employés that: "Beginning on July 1, after paying all expenses, taxes, and the interest on our bonds, we will set aside one-fifth of the surplus remaining, and during January next we will distribute this among all of you who are in the employ of the company on Dec. 31, 1903, in proportion to the salary of each. Anyone who leaves our employ before Dec. 31 will have no share in this fund. Anyone going on a strike shall forfeit his share. Anyone who comes with us at a later date will only receive his fair proportion. In other words, the distribution will be based upon the total amount of salary paid between July 1, 1903, and Jan. 1, 1904. Now, what can you do for yourselves and for us on such a basis? If you do not earn a surplus for the company of £1,000 a month during the rest of this year, I will be both disappointed and surprised. If the surplus averages £1,000 a month, it would make a total of £6,000 for the half-year. One-fifth of this would be £1,200. In June, 1903, we paid out a total of £2,348 in salaries Distributing such a sum on such a basis would give every one of you an interest in the profits equal to more than half a month's salary. Remember, the easiest way to make money is not to spend it. Do you realise that all of you are spending money for us? If you injure any part of our apparatus, you have spent the money it costs to repair it. If you cut wire to waste, you have spent the difference in value between good copper wire and junk. If you use a good sheet of paper to figure on where the back of an old envelope would serve as well, you have added to the cost of operating this plant." We wish the telephone operators of London were profit sharers.

"Electric Museum."—Mr. A. W. Hill, of Colombo, Ceylon, has started a fortnightly paper, which he has christened the *Electric Museum*. A feature is made of answers to correspondence, and the editor seems to have a wide range of useful queries to reply to in the first issue of his paper now before us. Amongst the "Museum" notes is the following: "An authority on forestry announces the discovery, in the primeval forests of India, of a tree with the most curious and inexplicable characteristics. Its leaves are so highly electrical that whoever touches one of them receives a severe electrical shock. Even upon the magnetic needle this tree has a strong influence, causing magnetic variations at a distance of 70ft. The electrical strength of the tree varies according to the time of day. It is strongest at noon, but its power almost entirely disappears at midnight. Its electricity also disappears in wet weather. Birds never rest upon its branches, nor have any insects been seen upon it." A forest of these trees would be as "thick" as the primeval forest at Epping, described by George Robey, which became so thick that the then London County Council had to close it. Mr. Hill has a reasonable explanation for the effects of wet on the above tree, but he does not attempt to explain its action on a magnet. Another editorial note is the following: "I note the interesting fact that at 10 p m., or so, one can observe a few dozen of frogs near the ornamental posts for electric arc lamps situated near the General Post Office in Colombo. It appears that a great number of flies and other winged creatures are attracted by the glare of the arc lamps; not being able to crack the glass globes, these flies soon fall to the ground exhausted, and are promptly devoured by the intelligent, patient frogs." This is a good argument in favour of electric street-lighting, and our contractors might supply an arc lamp, 12 spare carbons, and 24 frogs as a standard fly-catching plant. We wish Mr. Hill's venture every success.

Removing Silica from Coke.—In the manufacture of aluminium and other metals by electrolytic processes the carbon used in the electrodes must be free from silicon compounds, and particularly silica, otherwise, when the electrodes are consumed in operation, the silica originally contained in the same is taken up by the aluminium, thus yielding an impure product. In order to avoid this, it has been proposed to use in the electrodes petroleum coke, because it is practically free from silicon, but such coke is more expensive. Mr. Charles M. Hall, the inventor of the Hall aluminium process, has now devised a method, which has just been patented to him, for removing silica from the ordinary and cheaper kinds of coke. The method, which is described in the *Electrical World*, consists in mixing with the pulverised coke a metallic fluoride which will react with the silica, giving a fluoride of silicon, which goes off as a gas during the process of baking the electrodes. Sodium fluoride, cryolite, and fluospar give good results. The powdered coke and fluoride is then mixed with pitch or another suitable binder and formed into blocks, or whatever form of carbon is desired. These are then baked in a furnace of the form shown in a diagram. The wall of the furnace is built of brick, and in it the carbon blocks are placed, insulated from each other. In the centre of the furnace a core of a suitable material is provided which can be heated to an adjustable temperature by means of an alternating current supplied through binding posts. The temperature should be somewhat higher than in the ordinary baking furnace, in order to facilitate the chemical reaction between the fluoride and the silicon. Instead of mixing the coke, fluoride, and pitch, and forming them into the desired shape before baking, thereby combining in one process both the purification of the coke and the manufacture of the electrodes therefrom, the purifying step may be carried out separately by heating the mixture of coke and fluoride alone. The operation of the process in two steps has one advantage—namely, that the material then receives two heatings—thus insuring the completion of the desired chemical reaction.

Emanations of Radium—Sir William Crookes's paper before the Royal Society on the above subject is abstracted in a very concise manner in the current number of the *Journal* of the Chemical Society. Describing the experiments, the author states that in presence of some feebly luminous radium nitrate, a barium platinocyanide screen glowed with a green light, the phosphorescence disappearing whenever the screen was removed. A zinc sulphide or blende screen was found to be almost as luminous as the platinocyanide screen under the same conditions, but the residual phosphorescence lasted for some time. When the blende screen is tapped with a knife-point, a sudden spark of light is produced, and a scratch gives rise to an evanescent luminous line. An accidental contact of a few tiny particles of the radium salt with the blende screen caused the surface to become dotted over with specks of green light markedly larger than the inducing particles. A microscope, in a dark room, shows each spot to have a dull centre with a surrounding luminous halo, whilst outside the halo the dark surface of the screen scintillates with sparks of light. When solid radium nitrate is brought near the screen the scintillations increase rapidly in number and intensity, with the effect that after a certain point there is a residual phosphorescent glow, not observed when the scintillating points are few. A platinum wire, dipped in radium nitrate solution and dried, has the same effect if brought near the screen; if allowed to touch the screen it produces a luminous

Digitized by Google

spot, which is an active centre of scintillations for weeks afterwards. No variation in the scintillations could be detected when air was blown between the radium salt and the screen. Polonium sub-nitrate has a similar effect on a zinc sulphide screen, but the scintillations are less numerous. Comparison of the effects produced on platinocyanide and zinc sulphide screens by exposure to radium nitrate and polonium sub-nitrate leads to the view that the luminosity on the blende screen, whether due to radium or polonium, is caused by emanations which will not penetrate card. The scintillations caused by these emanations are distinct on the blende and feeble on the platinocyanide screen, because with the latter the sparks are seen on a luminous ground of general phosphorescence. The scintillations described above are regarded as associated with the impacts on the screen of the electrons thrown off by the radium salt, and from his experiments the author concludes that the number of electrons hitting the screen in a given time is not inconceivably great.

Echoes of the War.—The following official record of the South African War appears in the *Royal Engineers' Journal* for Aug. 1 under the heading "Electrical Engineers R.E. (Volunteers)." The searchlight detachment sent to South Africa in March, 1900, under the command of Major Crompton consisted of two sections. They were on arrival attached to the military railways, and worked under Colonel Girouard, R.E. A portion of the detachment, under Captain A. Bain, was detailed to repair the railway telegraphs in the Orange Free State and Transvaal. This portion remained throughout its service with the railways, and was employed in reconstructing and organising the railway telegraph and telephone systems, and the electric block and signalling system in the Transvaal and Orange River Colonies. Captain Bain acted throughout as chief engineer for railway telegraphs. The remainder of the detachment was employed during the reconstruction of the railway in lighting the deviations and bridges during construction. When the railway got through to Pretoria the detachment was placed under the C.R.E., Pretoria, acting as a separate unit, and not attached to any regular one. The men ran traction engines for transport, and put in order the electrical machinery in the forts. They installed and ran electric lights at Machadorp, Komati Poort, and at one of the general hospitals in Pretoria, current in this last case being supplied from the town mains; also installed and worked a defence searchlight at a colliery on the eastern line. The whole of the detachment returned to England in December, 1900. Almost immediately after the 1900 detachment returned home a new detachment, consisting of two companies, was sent out under Major A. Bain. The establishment was later on increased to five companies, organised as a battalion, the first and only complete battalion of volunteers from one corps that has served in the field during the history of the volunteer force. These five companies formed a distinct and separate command under Major Bain, who received his orders direct from army headquarters. They were employed on the following works: Lighting the large hospitals—*e.g.*, at Johannesburg, Pretoria, Elandsfontein, Kronstadt, Bloemfontein, Newcastle (Natal), Krugersdorp, De Aar (Cape Colony), etc.; erecting and running search lights at occupied townships—*e.g.*, at Heidelberg, Standerton, Ermelo, Vryheid, Vryburg, Komati Poort, Barberton, Middelburg, Klerksdorp, etc.; running searchlights on armoured trains; running traction engines; erecting and running ice-making plant—*e.g.*, at Newcastle, where from 1 to 1½ tons daily were turned out; lighting railway bridges—*e.g.*, Norvals Pont, Bethulie, Vereeniging; installing and maintaining electric light in army post offices, and in the offices of G.O.C.'s, etc.; working the large permanent installation in the artillery barracks, Pretoria; assisting the army telegraph department in permanent telegraph and telephone construction (a whole company being employed for a few months towards the end of the war on this last work); and, generally, doing any other electrical or mechanical work required for military purposes in South Africa—*e.g.*, connecting the defences by telephone and laying down electrically-fired land mines at O'Okiep, erecting a reliable electric signal and flare system on blockhouse lines, erecting and maintaining lighting of prisoner-of-war camps, etc. In every case this battalion did everything connected with their work without outside aid; erected, worked, and repaired (when necessary) all machinery; and in most cases erected engine-houses, etc., as well. They supplied some 65 working parties in Cape Colony, Natal, Orange Free State, and Transvaal.

Testing for Dielectric Strength.—At the recent Niagara meeting of the American Institute of Electrical Engineers, Mr. P. H. Thomas read a paper on the testing of electrical apparatus for dielectric strength. From an excellent abstract in the *Electrical World* we gather the author pointed out that while the only practical method of testing high-tension apparatus is by means of over-potential tests, yet the latter involves dangers, and great care should be taken to avoid injury to the apparatus, and excessively severe tests, especially long-time tests at high potential, should be avoided. A disruptive test fails partially of its object in testing the fitness of the apparatus for actual service, because the conditions of the test do not approximate closely the conditions of the service, either normal or emergency conditions. In general, electrical apparatus is never in a condition so poorly adapted to stand dielectric strains as when first installed. Insulation tests require special testing apparatus and expert and experienced direction, which are very often not available, and without which great risk is run in attempting such tests; as an exception it may be mentioned that some simple types of apparatus, such as high-tension series transformers, high-tension 'bus-bar insulation, etc., may be readily tested without great danger. Among the specific practical suggestions made by the author for tests of dielectric strength are the following: In high-tension apparatus—*e.g.*, 20,000 volts and above—only moderate, short-time, over-voltage tests should be specified in contracts. Such tests should be used once for all when the apparatus is known to be in good condition, preferably at the factory, by experts, to give assurance that the specification has been met. Such tests should not be made a second time. After installation, a considerably lesser test should made upon the apparatus, which will detect any serious injury in transportation and installation. Any moderate deterioration due to absorption of moisture, etc., will right itself with service, provided no abnormal deterioration has occurred. It is preferable to make high-potential tests by increasing the voltage upon the apparatus as it is designed to operate, one terminal at a time remaining grounded, rather than making a high breakdown test by voltage from an external source. On tests of very high-tension apparatus, such as generators and transformers, no breakdown gap should be used in connection with the determination of voltage. Any error in the voltage of test, provided precautions as to the proper size of testing apparatus are used, will be comparatively unimportant. In some cases the voltage of the testing device may be determined by means of a spark-gap before the apparatus to be tested is connected to the circuit.

THE DESIGN OF EXTRA HIGH TENSION SWITCHGEARS.

BY W. E. WARRILOW.

(Continued from page 196.)

The forgoing examples illustrate the assembly of boards in a comparatively small space, in spite of the voltage controlled, but such types are not actually suitable for dealing with circuits of any great power; they serve their purpose in small stations supplying scattered areas, but they are unable to cope with the enormous outputs which have to be controlled from power plants such as that installed at Niagara Falls. In these cases the tendency has been to adopt gears of the distance control type, the high-pressure sections being confined to isolated parts of the station, and all operating is carried out from a central table fitted with small switches closing low-pressure circuits connected to the actual gear itself. The high-tension switches are usually arranged on galleries above the control board, in the most convenient position for the leading in and out of the cables, a by no means unimportant problem in the assembly of the board. The energy for the operation of the switches can be derived from either a continuous or alternating current source, depending chiefly on the manner in which the switches are opened and closed. When motors are used the alternating type is employed, while for the direct actuation of the levers from pulling magnets continuous currents are found to be more suitable. In some instances pneumatic control of the switches is adopted, but the development of the electrically-operated device has now reached a degree of perfection which renders all mechanical methods obsolete.

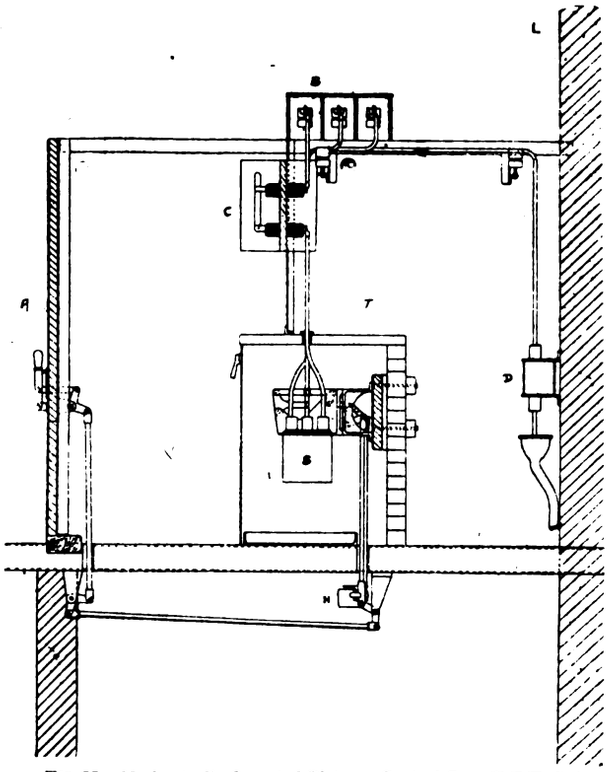

FIG. 18.—Mechanically Operated Distance Control Gear (B.T.H. Co.).

In certain instances, however, this form of gear with lever control can be adopted with advantage, and Fig. 18 will serve to illustrate the manner in which such a type of board can be assembled. An elevated gallery is preferable for the building up of the gear, as space is then allowable for the examination of the lever movements, bearings, etc. The working face of the board is comprised of marble panels mounted in an iron framework, the supporting stays of which serve the purpose of holding up the high-tension bars, B. For three-phase currents three separate switches are employed and mounted behind the marble slabs, in brick cells, fitted with an iron inspection door. The switch, one of which only can be seen, is shown by S, and each device is provided with a tripping solenoid, H, bolted under the platform, for releasing the mechanism on the passage of either an excess or reverse current; also a time-limit attachment can be introduced for the same purpose. In each instance the solenoid is connected to the secondary of the current transformer, D, fastened to the wall behind the entire gear. The interior of the switch can be seen in Fig. 19, though this design is suitable for bolting directly to a marble slab for operation with very

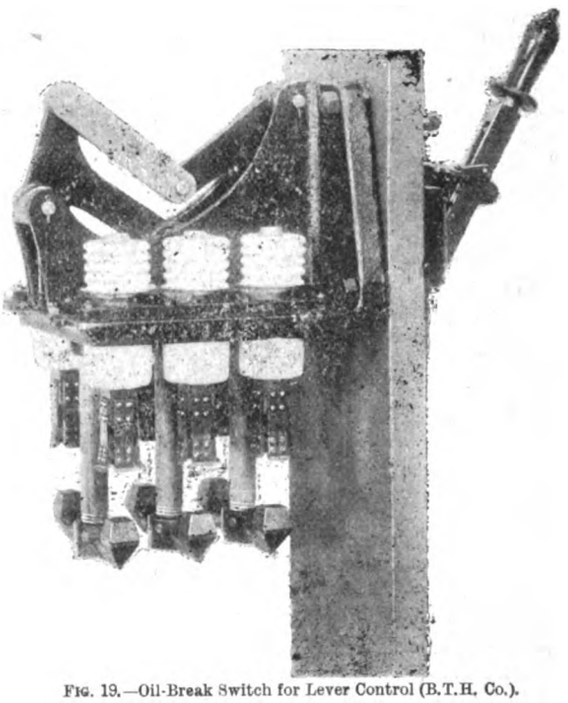

FIG. 19.—Oil-Break Switch for Lever Control (B.T.H. Co.).

short levers. The contacts are plainly visible, as well as the short-circuiting pieces, these being all coupled to one central operating rod attached directly to the link motion. The oil tank, of cast iron, has been removed to expose the contacts, but this receptacle can be easily raised into position, full of oil, without disturbing any portion of the gear in any way.

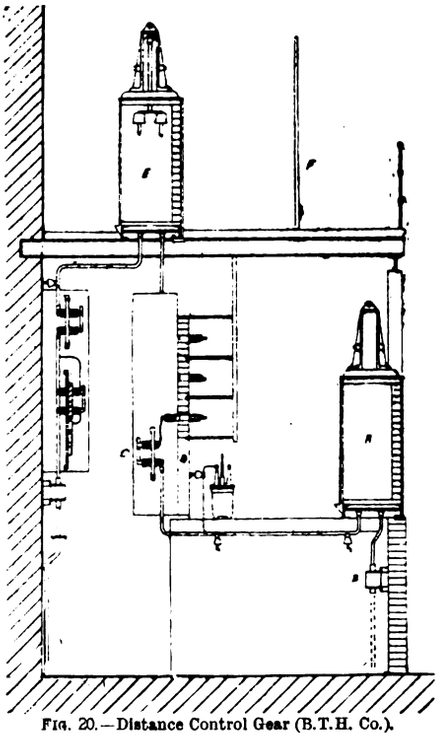

FIG. 20.—Distance Control Gear (B.T.H. Co.).

Referring, again, to Fig. 18, C is a switch which can be inserted for the purpose of isolating the main switches from the 'bus bars for cleaning or adjustment. Potential transformers for operating the shunts of the wattmeters (if there are any) can be mounted in the position shown at T, and if lightning arresters are used they are bolted to the wall above the main gear at L. The working face of the panels at A contains the fixings for the operating

Digitized by Google

levers, and all instruments, as voltmeters, ammeters, or wattmeters, can also be mounted on this part of the board. The section of gear illustrated in Fig. 18 is suitable for controlling pressures up to 6,000 volts.

A sectional lay-out of a gear designed for the handling of currents at 10,000 volts is illustrated in Fig. 20, the switching devices in this case being all electrically operated. The cables from the generator enter a switch at A, after passing through a current transformer, B. Thence the conductors are laid on insulators as far as an isolating switch, C, from which they are connected directly to the 'bus bars mounted on insulators in the wall, D, erected for the purpose. Thence the cables pass to feeder switches fixed to the upper storey of the gallery at E, finally leaving the gear through another isolating switch and current transformer. The small control panels are mounted at F on the operating platform, all the low-tension switches, instruments, wattmeters, etc., being attached to this section of the board. The electrically-operated switch is shown in Fig. 21, the parts in question being fitted to a wooden framework, though when in actual use the device is mounted in a brick chamber with cast-iron top. The circuit is broken

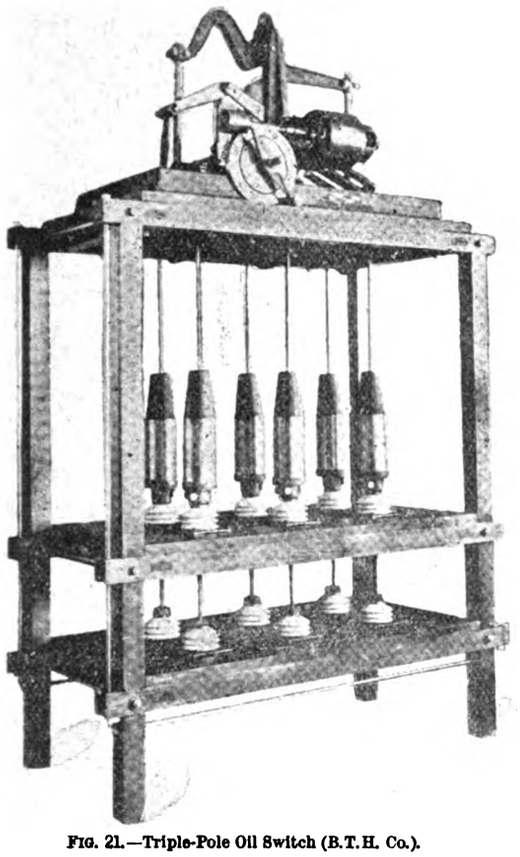

FIG. 21.—Triple-Pole Oil Switch (B.T.H. Co.).

in oil tubes cemented in insulators, the tubes containing contacts for the reception of the short-circuiting rods attached to the operating mechanism. It will be seen from the illustration that the switch is actuated entirely by an electromotor mounted on the top platform—that is, above the chamber containing the tubes; and this motor is of the series type, having an output of ½ h.p. The motor shaft carries a solenoid for connecting it to the operating mechanism through worm gearing, the magnet being energised when the motor switch is closed. A system of links and levers, coupled with a toggle motion, aided by powerful springs, enables the motor to wind up these latter, and also set the crank pins just off the dead centre, so that the slightest movement of the motor releases the toggle and allows the energy of the springs to be expended in either opening or closing the switch. Current for the motor is obtained from the secondaries of current transformers (these serve the purpose of providing low-tension circuits for the main ammeters), and small switches are fitted to the control board, which is mounted on a gallery some distance from the chamber accommodating the extra high tension gear. Signal lamps are included in this equipment to indicate to the switch hand that the motor has operated properly, and in some instances the main switches themselves are connected two in series, reliance being placed on one to open the circuit in case of failure with the other. The above-described switch is constructed for dealing with pressures up to 30,000 volts and currents to 50 amperes.

(To be continued.)

NOTES ON THE SPEED REGULATION OF CONTINUOUS-CURRENT MOTORS.

BY WALLACE ROGERS.

When a conductor carrying a current is placed in a magnetic field, it will be turned in such a direction that the E.M.F. induced in it by this motion will oppose the flow of current existing in the conductor. This law which gives us the theory of the motor states that under the conditions mentioned above there will be motion; it also gives the direction of motion. From this is derived the fact that the speed of a motor depends directly upon the impressed E.M.F. at its terminals, and inversely upon the strength of the magnetic field and the number of armature conductors. Hence any increase in the impressed E.M.F. will increase the speed, which is also increased by a decrease in the field strength. A motor always runs at a sufficient speed to generate a counter E.M.F., which is nearly equal to the impressed E.M.F., the difference between them increasing with load, the speed at any instant always satisfying the equation: counter E.M.F. + C R_a = impressed E.M.F., C R_a representing lost volts in the armature. Under no conditions could the counter E.M.F. equal the impressed voltage, seeing it is impossible to construct an armature having no resistance. The effect of putting load on a motor is to decrease the speed and lower the counter E.M.F., allowing a larger current to flow, and increasing the C R loss till the factors in the above equation are again balanced. The speed of any motor is proportional to its counter E.M.F., and if the armature and field resistances are low the speed may be said to vary directly as the impressed voltage. On the other hand, if these resistances are high, the speed will not vary directly as the impressed voltage, but as the difference between it and the C R loss (which is the counter E.M.F.). An example might simplify matters. Suppose that with an applied terminal voltage of 500 we get a speed of 200 revolutions per minute, it does not follow that we shall get a speed of 400 revolutions per minute if the applied voltage be raised to 1,000 volts, and to find out what speed we should have with the increased voltage it would be necessary to know the current value at which both tests were run, and also the internal resistance of the motor. We will suppose current = 30 amperes and R = 3⅓ ohms.

In first case C R loss = 30 × 3⅓ = 100 volts; ∴ speed of 200 revolutions per minute is given by (500 − 100) = 400 volts—*i.e.*, two volts give one revolution.

In second case 1,000 volts will give $\frac{1,000-100}{2}=450$ revolutions per minute.

Suppose R is lowered to one ohm, then C R loss = 30 volts; ∴ volts to cause motion = (500 − 30) = 470 volts.

Here 200 revolutions are given by 470 volts; ∴ one revolution is given by $\frac{470}{200}=2{\cdot}35$ volts; ∴ speed given by 1,000 volts $=\frac{1,000-30}{2{\cdot}35}=\frac{970}{2{\cdot}35}=412$ revolutions.

This example shows us that only when R is small is the speed proportional to the impressed voltage. Let n = speed, e = counter E.M.F., F = magnetic flux, c = number of armature conductors, then $n=\frac{e}{F\,C}$. This formula shows us that to increase the speed we must decrease the field strength (C being a constant quantity). This is because the armature when running in the weakened field cannot generate such a high counter E.M.F., hence a larger current flows through it, causing it to run at a higher speed. The speed of a shunt motor may be represented by $\frac{E-C\,R}{N\,F}$, where E = supply voltage, C = armature current, R = armature resist-

Digitized by Google

ance, N = number of armature conductors, F = flux. It increases about 20 per cent. upon removal of load, but a series motor races badly if its load be removed, because any decrease in the armature current decreases the field strength.

So far we have only considered the effect of weakening the field as a means to speed regulation, which method has two disadvantages: firstly, as the motor field becomes weaker its electrical balance falls off; secondly, the torque disappears if the field is weakened below a certain point. We will now consider other methods of regulating the speed. To control the speed of a motor, it is necessary to apply to the armature terminals a voltage corresponding to the desired speed, and this may be done in several ways. One method is that known as rheostatic control. It consists in passing the applied voltage through a resistance before it reaches the motor, this resistance being varied to consume the excess of voltage over that required to produce any particular speed. The disadvantages of this method are: firstly, that it is very inefficient, seeing the voltage consumed in the resistance is a dead loss; secondly, if this voltage is large, it means that a large amount of heat has to be got rid of. Another method, known as the teaser system, consists in supplying the working motor with current from a small generator wound for large current capacity and low voltage, this small generator

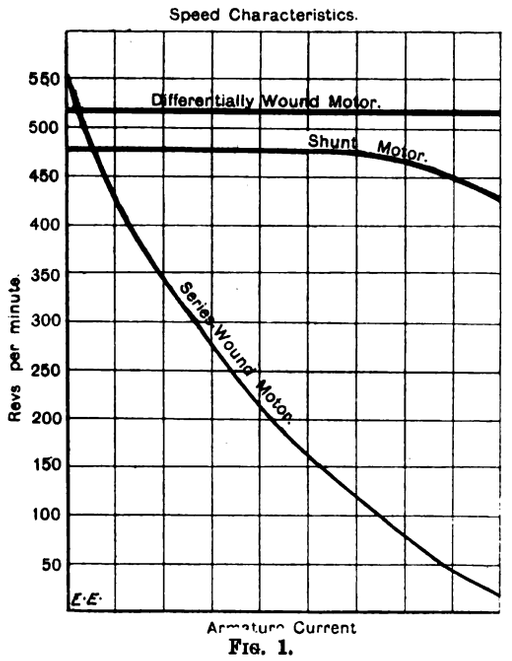

FIG. 1.

being driven by a motor which takes current at full voltage from the mains. The efficiency of this system is questionable, seeing it requires two auxiliary machines. If a motor be designed so that the loss of E.M.F. due to armature reaction is equal to the C R loss in the armature, it will run at constant speed with varying load. As this condition is not fulfilled in the design of present-day motors, we can only obtain constant speed with varying load by suitable regulation. As this is required in certain classes of work, it is usual to employ what is known as a differentially-connected compound-wound motor. In this type of motor the shunt and series coils are connected in opposition, the shunt winding being made strong enough to always control the polarity of the field. These motors maintain constant speed with varying load, owing to the fact that as the load increases a larger current flows through the series coils, whose demagnetising action over the shunt field increases, resulting in a weakening of the field and a corresponding rise in speed. The two windings must be so proportioned that the weakening effect of the series coils just compensates for the fall in speed due to increased load. The speed regulation is perfect only when the voltage across the mains is that for which the motor is designed, and also when the load varies between zero and a maximum, and not beyond the capabilities of the motor. Such a motor must be started up in the same way as a shunt motor, otherwise the strong initial series field will overpower the shunt, and reverse the direction of rotation. When starting up it is usual to short-circuit the series winding, and, in some cases, make it agree with the shunt, thus giving the motor a large starting torque, at the same time preventing it from starting in the wrong direction. After full speed is reached and the armature current falls to its normal value, the series coils are again short-circuited and reversed, restoring them to their normal condition of opposing the shunt winding. To obtain a constant speed at all loads, the series winding must be so proportioned that it is capable of reducing the counter E.M.F. sufficiently to allow a larger current corresponding to the increased load to flow through the armature. The curves in Fig. 1 show the difference between the speed characteristics of series, shunt, and differentially wound motors, from which it will be seen that where perfect speed regulation is required, it is necessary to use a motor having differential windings; but for most purposes the speed regulation of the shunt type is quite satisfactory. Although the differential compound-wound motor (when started up in

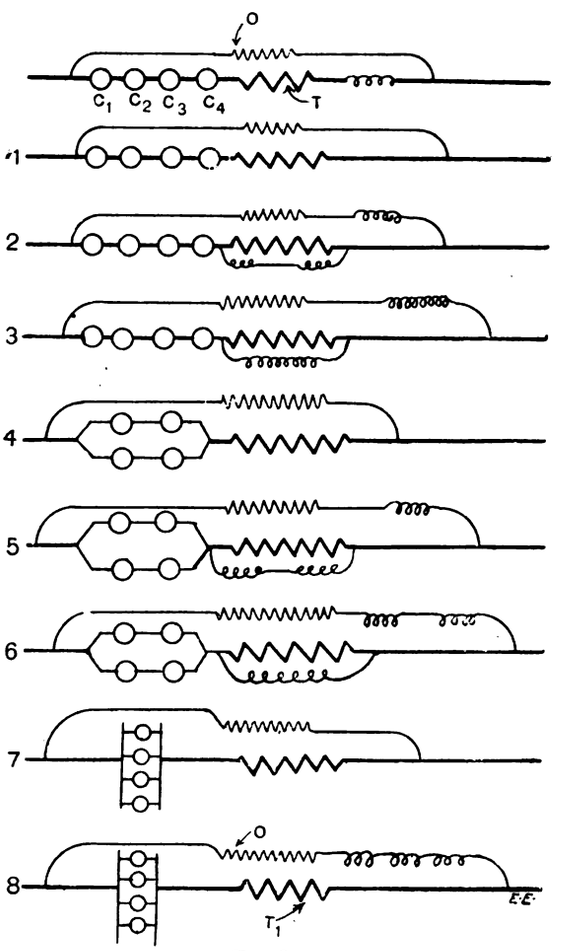

FIG. 2

the manner mentioned above) combines the large starting torque of the series motor with the good speed regulation of the shunt type, its efficiency is not very high, because more energy is expended in the field to produce a given magnetisation, as some of the lines of force are continuously being neutralised.

We have only considered speed regulation so far as it concerns motors used for stationary work. We will now consider it in connection with traction work, where this question is of equal importance. As regards traction motors (which are, of course, series wound), speed regulation is obtained by starting the motors in series with themselves and some external resistance, subsequently by steps putting them in parallel. A more efficient method is that due to Sprague, who made use of the counter E.M.F.'s of the motors as a means to speed regulation. His method was to divide the field windings into several sub-divisions and commuting them by means of a special controlling switch so as to change their influence upon the magnetic field, the result of this being a variation in strength of the counter E.M.F.'s of the motors. Although this method appreciably

Digitized by Google

reduced the amount of external resistance necessary for wide variations of speed, it did not do away with its use altogether owing to the small variation in field strength it was possible to obtain.

The latest method of speed regulation in traction work is that introduced by Lundell. In this system the principle of series-paralleling from two armature circuits to four, is combined with the series and shunt methods of excitation, together with the Sprague method of varying the field strength. The whole combination gives complete control over current and speed over wide limits, relying solely upon the ohmic resistance and counter E.M.F.'s of the machines, external resistances in the armature circuits being completely done away with. This is brought about by furnishing each motor with two armature windings, two commutators, and a field magnet so constructed that it will be possible to run with a weak field without excessive sparking. Fig. 2 shows a diagram of the various circuit combinations for two railway motors constructed on the above principles. O represents the shunt windings, T the series windings, C^1 C^2 commutators for one motor, C^3 C^4 commutators for the other motor. As it is possible to obtain a varying field strength, each armature combination, excepting the parallel one, yields three different speeds. The first three combinations (first, second, and third) give 125 volts per commutator (with 500 volts on line), the motors working practically as shunt motors, owing to the very strong shunt and the weak series field. The next three speeds (fourth, fifth, and sixth) give 250 volts per commutator. The series fields have become stronger, and at the seventh position are four times as strong as at the first position. At the eighth position they are further strengthened by an increase in the current flowing through the armatures. When top speed is reached the motors are practically working as series motors, seeing the shunt field has been greatly reduced owing to the insertion of additional resistance in series with it. It will be seen that the speed of the motors depends upon their counter E.M.F.'s, which in turn depend upon the grouping of the armature windings and the field strength. This system has the following advantages: When the speed of the motors exceeds the speeds corresponding to a certain position of the controller, by reason of the car running down hill, the motors will become dynamos and restore energy to the line. Secondly, when any series-parallel changes are effected, the number of watts to be broken at the controller contacts is very small, being equal to the difference between the line voltage and the counter E.M.F. multiplied by the main current flowing at the time, or watts = (impressed E.M.F. – counter E.M.F.) × C. The great advantages which this system has over the older methods of speed regulation in traction work brings one to the conclusion that, although not impossible, it will be very difficult to improve upon it.

RADIUM AND OTHER RADIOACTIVE SUBSTANCES WITH A CONSIDERATION OF PHOSPHORESCENT AND FLUORESCENT SUBSTANCES. THE PROPERTIES AND APPLICATIONS OF SELENIUM AND THE TREATMENT OF DISEASE BY THE ULTRA-VIOLET LIGHT.*

BY WILLIAM J. HAMMER.

(Continued from page 197.)

Dolezalek has designed a very sensitive type of electrometer built by Bartels, of Göttingen, a description of which may be found in *Verk, der Deutsche Physik Ges.*, III. (1901). It is well known that the leaves of a gold or aluminium foil electroscope will hold their charge in dry air indefinitely, but the Becquerel rays are found to dissipate the charge by ionisation of the air, or rendering the air a conductor of electricity (the electroscope may also be discharged by Röntgen rays, cathode rays, and ultra-violet light). In Fig. 5 is shown a form of electroscope devised by the Curies for the study of radioactive substances. Referring to the diagram to the right, it will be noted that the electroscope consists of a single movable sheet of gold or aluminium foil attached to a stationary sheet of copper, L, being supported by the insulating piece, I. The radioactive substance to be tested is placed on the lower of the discs, P and P', preferably on a removable plate. The radiations make the air a conductor between these two plates. The electroscope is charged by means of a stick of ebonite rubbed briskly and placed near the rod, B. This deflects the sheet, L', from the vertical, and it so remains for a very long time. When radioactive substances are brought near it, the gold or aluminium leaf is caused to lose its charge, and the leakage is observed by means of a stationary telescope shown in the left-hand figure, which is provided with a micrometer scale. The time taken for the discharge of the electroscope is taken by means of a chronometer or watch. By suitable lighting the front edge of the foil may be made to appear as a very fine line, and its position noted with great precision. By examining the diagram it will be noted that the upper condenser plate is connected with the metallic case. Detachable metal cases are placed over the condenser plates and over the rod for charging the electroscope. Two of the sides of the case are of glass. I have here a simple form of electroscope with leaves of aluminium foil, which serves to show the ionisation of the air; when the radium is brought near, the divergent leaves

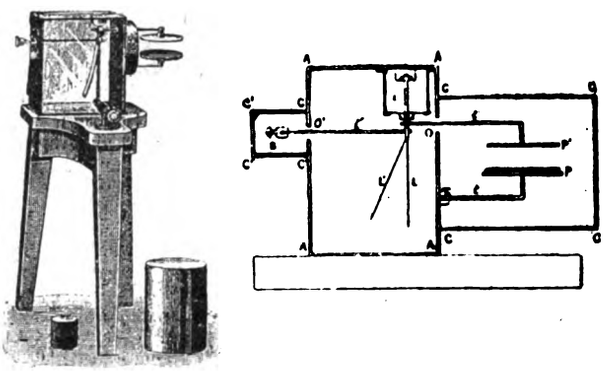

FIG. 5.—Curie's Electroscope for the Study of Radio-activity.

lose their charge of negative electricity and rapidly come together. It is of paramount importance that the radioactive substance should be kept in a room distant from the electroscope.

At the present moment the clothes of every person in this room and all the walls of the room are radioactive by reason of the presence of the nine preparations of radium which I have here this evening. Prof. Curie told the writer that it was often impossible for him to go near his instruments to make any measurements for hours, after being in the proximity of some radium, and those who have worked with this substance have found the greatest difficulty in keeping their tools and instruments and themselves free from the radioactivity imparted by the radium. The energy represented by radium is something enormous. Elster and Geitel have shown that a fine wire of any metal placed in the atmosphere and charged negatively from some source of current, say of 500 volts, causes the wire itself to become radioactive, and this radioactivity may be scraped off and will affect photograph plates, ionise the air, etc. It cannot, however, be washed off. It is stated that lightning rods and even the leaves of trees all become radioactive, and it has been shown that falling rain and snow are for a time quite powerfully radioactive; and after they have fallen, a wire negatively electrified in the atmosphere has only a small amount of radioactivity, apparently showing that the rain and snow have carried the radioactive particles in the atmosphere down to the ground. McLennan has made experiments with the negatively charged wire in Montreal, and subsequently at the foot of Niagara Falls, and has found the result about one-sixth as powerful in the latter place as in the former; and he has also shown that it was not necessary to electrify the wire used at Niagara Falls, as it received a sufficient charge from the electricity

*A lecture delivered at a meeting of the American Institute of Electrical Engineers and the American Electrochemical Society, New York, April 17, 1903.

Digitized by Google

in the atmosphere. McLennan found that rain caught in a vessel and immediately evaporated to dryness imparted radioactivity to the vessel in which it was evaporated. Ordinary water when evaporated and rain-water which has stood for several hours before being boiled down do not yield any radioactivity.

As an evidence of radioactivity imparted to another substance by radium, I have here some pieces of cardboard which constituted the box which held my samples of radium for several months. The box becoming injured, I broke it up, fortunately saving the pieces; and six days after the radium had been removed I looked up the pieces, and was surprised to find them luminous in the dark. Subsequently I tried their effect on a photograph plate, but did not succeed in getting any impression. Three weeks later it occurred to me to try and stimulate the radioactivity of the cardboard, which had not been near radium for over a month, by burning magnesium wire, when I found I could make the cardboard brighter than it had been in the first place. I have also stimulated the radioactivity by sparks from a coil, especially when producing ultra-violet rays, by using a condenser bridged across the secondary and employing pure iron electrodes. I tried the burning magnesium with various samples of cardboard which had not been exposed to the radium, and there was no phosphorescence. It has already been stated that various substances which become radioactive retain that property for a short time only, and it is interesting to note its retention for such a long period of time, and to note this ability to stimulate and make visible the imparted radioactivity. This experiment suggests the discovery made by Prof. E Wiedemann that a mixture of sulphide of calcium with a little sulphate of manganese is not altered when exposed to cathode rays, but some time after its exposure it bursts into a vivid greenish glow when slightly heated, and to this phenomenon he has given the name "thermo-luminescence." Prof. S. P, Thompson also showed that fluorspar which by prolonged heating has lost its luminescing power, regains the power of thermo-luminescence on exposure to Röntgen rays when reheated. Prof. Trowbridge also finds that this restoration is also effected by exposure to the electric glow discharge, but not by exposure to ultra-violet light. It also stated that an object coated with calcium sulphide, and exposed to the sunlight, will phosphoresce about 10 hours, and even after it has lost its luminosity, it can be caused to again give light by heating first by the hand, then over a water-bath, and finally on a hot stove. McLennan has found a very large number of salts are brought into a condition by cathode rays, in which warming makes them radioactive for a short time, the supply of negatively-charged particles discharged from the surface coming to an end.

Prof. Rutherford, of Montreal, who has given a great deal of attention to radioactive substances, particularly to investigations into thorium, which next to radium is the most radioactive substance yet discovered, has found that by electrifying a wire negatively with a current of 500 volts connecting the positive pole to the ground, and by connecting a sample of thorium to the earth, that the thorium particles were attracted to the negatively-charged wire, producing a greater radioactivity than he had ever found in any thorium preparation which he had made. I have here a sample of oxide of thorium, the radioactivity of which was discovered independently by Schmidt and Curie. This sample is between 98 and 99 per cent. purity. From this body Prof. Rutherford has isolated a substance which he calls "ThX," and, extraordinary as it may seem, it has been found after separation of the active constituents represented by the ThX from the thorium, that the ThX loses its radioactivity, and this is taken up by the thorium in exactly the amount which the other loses. Sir William Crookes has also separated a non-uranium residue from uranium, leaving the matter without radioactivity. Whilst the whole of the radioactivity has been concentrated in the residue to which the name UrX was given, Crookes, as already stated, claims that actinium is but another name for his UrX. The only case of radioactivity induced by cathode rays in a neutral substance has been that of bismuth, discovered by Villari. Prof. Curie has discovered that radioactive gas emanates from radium, and Rutherford has discovered the gaseous emanations from thorium. Messrs. Rutherford and Soddy have investigated extensively these emanations, and they have succeeded in condensing them at the temperature of liquid air. A preliminary account appears in the *Proceedings* of the Chemical Society of London for December, and Prof. Rutherford writes me that the full paper will shortly appear in the *Philosophical Magazine*; and he states furthermore that in his opinion this proves beyond doubt the gaseous nature of the emanations.

The serious physiological effects of radium are well known, and Messrs. Giesel, Becquerel, the Curies, and others, have given important evidence thereof. As stated in the appendix of a paper read by the writer at the one hundred and fifty-ninth meeting of the institute on Jan. 3, 1902, dealing with the subject of radioactivity, Prof. Curie told the writer that he would not care to trust himself in a room with a kilo of pure radium, as it would burn all the skin off his body, destroy his eyesight, and probably kill him. The writer felt the effects for weeks of a slight burn from inadvertently carrying a wooden box containing eight tiny sealed glass tubes of radium under his arm for several hours. Mr. W. E. Hidden has called the attention of the writer to some phenomena which he has observed in a mine in Barringer's Hill, Llano County, Texas, which mine contains yttrium, thorium, and uranium. Pockets of ore have been found, ranging from a few ounces to a capacity of 70 kilos, which were the nuclei or focal points of rigid lines radiating in every possible direction. These lines penetrating great masses of quartz and orthoclase feldspar, and gigantic pegmatyt, to distances often of several feet—in some cases of from 5ft. to 8ft.—he has observed that these radial lines were fissures, and bore no relation to the natural cleavage or the crystalline form of the huge rock masses in which they existed. Easy parting took place along these radial lines, making the ore quickly available. It is Mr. Hidden's theory that, as these lines directed to ores rich in uranium and thorium, both well-known sources of radium, etc., the phenomenon is due to an electric or other effect of radioactivity; it being untenable, he believes, to explain this phenomenon on the basis of expansion or contraction. The slide which I will show on the screen shows clearly a pocket of ore with the lines radiating therefrom in all directions.

Eighteen years ago, while in Italy, the author visited the celebrated aquarium in Naples, which is probably the finest in the world; and while there was enabled to test the shocking abilities of the electric ray, or "torpedo Galvani," and was astonished at the tremendous shock which he received; and in this connection it is interesting to call attention to the fact that there are 50 or more fishes which are known to possess this property of giving powerful shocks. The "gymnotus," or electric eel, and the "torpedo Galvani," or electric ray, being the best known of these. It will be recollected that Faraday drew a powerful spark from a gymnotus at the Polytechnicum, London, and he estimated the shock to be equivalent to that given by a battery of Leyden jars of 3,500 square inches of surface. And many writers have referred to the ability of these electric fishes to give powerful shock for a long period of time. D'Arsonval has caused them to light incandescent lamps, and they have been known to magnetise needles and decompose water by the electricity they produce. These fishes doubtless using this faculty as a means of defence and also for procuring food. My object in mentioning this is to state that last fall I again visited Naples, and thinking that perhaps an electric torpedo was on exhibition, it occurred to me to take with me some half-dozen tubes of radium which I had in my bag, and see whether the radium had any effect upon the power of the fish to give powerful shocks. The fish, as at the time of my previous visit, was lying in a shallow wooden box containing wet sand and a small amount of water. By taking hold of the side of the fish and pressing with the thumb on one side and the fingers on the other, or by either pinching or tapping the fish, the cells with which the fish was equipped discharged themselves, and gave a shock sufficient to twist one's arm very badly. After the members of our party had each received a shock, and as soon as a few persons present had gone away, I laid the

Digitized by Google

six tubes of radium on the fish (which is shaped very much like a flounder), leaving them there for about 20 minutes. I then replaced the tubes in the box, and taking hold of the fish tried for 15 minutes to get it to give me a shock by tapping or pinching in the same manner as previously done when the fish gave off shocks, and without receiving the slightest shock. Now, I am prepared to admit that the fish might have been "entirely out of shocks"; still, it is well known that these fishes will continue to give out shocks for a very long period of time, one authority reporting 360 shocks in seven minutes' time; but after exposing the fish to the radium I could get absolutely no manifestatien; and in this connection, it is to be remembered that the physiological effects of radium, such as burning, destroying microbic life, producing the sensation of light when a tube is held against the closed eye or temples (which is doubtless largely due to the phosphorescence of the pupil of the eye, but which may also affect the nerve centres), and also the electrical effects, where charged bodies are caused to give off their charge by the ionisation of the air; and one must also remember the very numerous chemical effects and the destruction of the germinating power of seeds, the changing of oxygen into ozone, and various other phenomena of radium which would lead one to wonder whether the radium did not affect the ability of the fish to give off electric shocks, perhaps producing a partial paralysis. The experiment is of some interest, and may be, perhaps, repeated by others who have better facilities than I to continue the investigation. I have sometimes wondered how that fish was getting along in Naples, though I believe the waters of the Mediterranean abound in them. *Note.*—Since writing the above description of his own experiments, the writer has learned of the recent experiments conducted by Prof. Curie, in which a few milligrammes of radium introduced beneath the skin of a mouse near the vertebral column produced death by paralysis in three hours; and tubes of radium placed in contact with the back of the necks of guinea pigs have killed or paralysed these animals in a few hours, according to the length of exposure to its fatal radiations.

As illustrating the action of radium rays upon bacteria, E. Aschkinass and W. Caspari speak of exposing cultures of *micrococus prodigiosus* to a radium preparation, and state that the rays killed the germs very effectively in about three hours. The work of Rutherford, the Curies, Becquerel, and others has demonstrated that there are three entirely distinct types of rays emanating from radium (Rutherford having first pointed out that uranium possessed two separate types of rays, α and β, the former easily absorbed even by gases, whilst the latter are very penetrating and but little absorbed by gas). Those which constitute by far the most important class are the α rays. They constitute the major proportion of the rays, and are those which produce the greatest portion of the ionisation of the gas, which has been observed under experimental conditions. These α rays possess in common certain characteristics of Röntgen rays, and by many have been thought to be Röntgen rays. I shall call your attention later to certain effects which are identical with those produced by Röntgen or X-rays. They have been considered absolutely non-deviable, as X-rays have been held to be. Rutherford has, however, recently shown that in a very powerful magnetic field he could deflect about 30 per cent. of the rays, and in experiments now being conducted with a strong electric field he has been able to deflect about 45 per cent. of the α rays. The α rays are readily absorbed, and a thin screen of metal will serve to cut off the greater portion of them. In this connection I would state that Mr. Tesla informed the writer recently of an experiment he had made in which he had succeeded in deflecting the X-rays themselves, and M. Blondelot has recently claimed as the result of his experiments that X-rays are susceptible of polarisation. If this is so, it is argued they may be shown to be ordinary light waves of extremely short wave-length. Strutt and Crookes have suggested that the α rays consist of positively electrified particles, and this view Rutherford supports, calling attention to the fact that they possess characteristics similar to the "Canal Strahlen" of Goldstein. These Goldstein rays have been shown by Wien to be positively charged particles, moving at high velocities. Rutherford, as a result of his most recent observations, considers that the α rays move at much higher velocity than the Goldstein rays, and he estimates that the energy of the α rays is a thousand times greater than that of the β rays. Rutherford says all the radioactive substances, including polonium, as well as excited bodies and the emanations, give out α rays. The β rays are much more penetrative and much longer, and in every particular correspond to the characteristics of cathode rays. They are readily deflected by a magnet. They discharge electrified bodies by ionisation of the air, affect photograph plates, etc.

M. Villard, in 1899, proved that the cathode rays are negatively electrified corpuscles or fragments of atomic hydrogen, and these corpuscles, as they were named by J. J. Thomson, which he has shown to be one one-thousandth of the mass of the hydrogen atom, are projected from the cathode at a speed approximating 70,000 miles per second. The γ rays are the rays possessing the greatest penetrative effect. They will excite or produce radioactivity through the air at a distance of 3ft. or 4ft. or more. Some recent experiments made by Rutherford show the relative penetration of the three classes of rays through aluminium sheets of varying thicknesses, before a loss is observed of half of the intensity, and this shows for the α rays a thickness of aluminium of ·0005cm., β rays a thickness of aluminium of ·05cm., γ rays a thickness of aluminium of 8cm. Mr. Rutherford, who has conducted most painstaking investigations into the penetrative character of the radiations from uranium, radium, thorium, etc., recently wrote the author, in answer to some questions on the subject, that he had found that the radium rays were reduced to half value after passing through 1cm. of lead, 1in. of iron, and about 8in. of water, the radiation being reduced to about 1 per cent. of its original value, after passing through 7cm. of lead, 7in. of iron, and 56in. of water.

In the lantern slide thrown on the screen is an interesting illustration of the effect of magnetism on the deflectable rays from radium. There are four large steel magnets, two being placed opposed to each other, and the other two so that unlike poles are opposite to each other, making a strong field of force between the two magnets. I have placed six tubes of radium a short distance above the magnets, and in a line running across and between the poles of the two pairs of magnets. It will be seen that the magnetic rays in the case of one pair of magnets have repelled the radium rays, so that the negative is but slightly affected; whereas, in the case of the other pair of magnets, the radium rays have been attracted by the magnets affecting considerably the negative around the pole pieces. Prof. Curie states that half of the induced radioactivity, when exposed to the air, is lost in certain substances in half an hour; but in a closed vessel where the air has been made radioactive, however, this radioactivity has not lost half its strength even after four days' time. It is desirable to keep radium free from moisture, preferably in sealed glass tubes. It readily takes up moisture, and then soon loses its luminosity, which may, however, be regained by dissolving and precipitating the substance and thoroughly drying it.

The luminosity may also be considerably heightened by subjecting the radium to high temperatures. Polonium like uranium, does not possess the power of exciting radioactivity, as it does not give off any emanations, whereas in the case of radium and thorium, there is an actual emanation, producing radioactivity in surrounding objects by the deposit of radioactive matter. When one considers the remarkable effects produced by radium it would almost seem that it is matter tearing itself into tiny pieces, and projecting these infinitesimally small particles through all matter at a speed from half to even the full speed of light, and rendering all substances about it radioactive, and still without appreciable loss in weight in the original substance, and, without disparagement of the accepted wave theory of light, one naturally "harks back" to Newton's corpuscular theory of light.

(To be continued.)

APPRENTICESHIP IN ENGINEERING TRAINING.*

BY PROF. JOHN DEWAR CORMACK, B.SC., A.M.I.C.E.

The subject of this discussion is wide and complex, and as the scope of the title may be misunderstood it is well at the outset to make it clear, although it may seem, at the same time, to be extended and restricted. "Engineering" is to be understood as including all branches—to be, in fact, civil engineering in the wide meaning of the term. The use of the word "apprenticeship" may, to some, indicate that only one or two branches of engineering are to be considered, and to others it may seem that it is the training of the workman which is to be the subject of the discussion. But an apprentice is simply a "learner"; whatever be the branch of engineering, or whatever be the aim or the ultimate end of a young engineer—whether he is to be a workman, or whether he is to be an employer—during his apprenticeship he is a learner. The title therefore includes "pupil," although this term is sometimes used to distinguish a learner in certain branches, while in other branches it is used to distinguish the "paying" apprentice who aims at being an employer or designer, from the "paid" apprentice who becomes a workman. These extended definitions embrace too wide a field, and it is necessary to limit it by confining ourselves to the training of youths who are destined to be employers, manufacturers, or consulting engineers, designers, heads of departments, technical managers, and men in responsible positions. Whether or not such an apprentice should pay or be paid is a matter for the decision of individual engineers, or engineers in different branches, and this question may therefore be left out of the discussion.

Until the beginning of the last century, entrance into the trades and the professions could only be obtained by means of an apprenticeship extending over seven years, during which the apprentice was bound to serve a master, who, on his part, undertook to keep the apprentice and to teach him his work. The system, as it then was, led to many abuses, and the Act of 1814 was designed to counteract these. It opened wide the doors to all except a few professions, and no restriction was placed either on the manner in which a youth learned his future occupation or the duration of his training. At that time engineering, except in a few branches, was just emerging from its position among the crafts. The removal of the restrictions to entrance may have been harmful in some ways, but at all events it allowed free entrance to many men who, although trained for other purposes, became pioneers in different branches of engineering. Although the restrictions were removed, there still remained the idea that the proper way to become an engineer was to spend a period of five years or seven years in the workshop or office. Probably then, in the existing state of what we are now proud to call the profession, this was desirable, but now, after a century which has seen vast developments in engineering practice, and during which, with ever-increasing rapidity, scientific discovery is turned immediately to practical utility, it seems reasonable that some more generally recognised system of apprenticeship should be devised or recommended to suit the new conditions.

The inadequacy of the old system of apprenticeship has been realised for some time; so long ago as 1866, Sir John Fowler laid stress on the importance of combining the study of science and engineering theory with the ordinary apprenticeship. Since then it has become more generally recognised that the proper training for an engineer involves training both in theory and practice, and this has for the past seven years been emphasised by the institution in demanding a knowledge of theory from candidates for associate membership. When the technical education fever was at its height, opinion, to some extent, went to the other extreme, and it was thought by many that at last we had arrived at the solution of the problem. The numerous universities and technical colleges were expected to be able to turn out young engineers equipped not only with the necessary technical knowledge, but with experience gained in the college workshops. In the United States and on the Continent this system of training has been, to a large extent, adopted, but there are indications of an increasing tendency to diminish the workshop practice in the colleges, and to substitute a training in workshops under commercial conditions. Especially in the case of the United States does one see excuse for such a system, for the extraordinary rapidity of the increase of engineering business there has created a corresponding demand for young men possessed of scientific knowledge and some technical training, and capable of filling responsible positions. In this country, however, starting with a pre-eminent position in engineering, we have advanced with the times—perhaps at a less rapid rate than elsewhere, but still with sufficient prosperity. Interest in the training of young engineers has not been so generally aroused. Biassed as some were by the old traditions, infected as were others by the technical education fever, the advice given to our young engineers has been very varied, with the result that at present training is in some quarters found to be in a rather chaotic condition.

The ever-increasing keenness of international competition urges us to a solution of the problem, and this alone should be sufficient; but the call seems still more emphatic when we remember that the function of the engineer is "to direct the sources of power in nature to the use and convenience of man," and realise his cosmopolitan duties. The beneficial directing of the forces of nature implies a knowledge of the laws governing their behaviour. The definition of the title "civil engineer" demands from him both theoretical knowledge and practical experience, and in this discussion I think we may take as agreed that both are essential in the training of the engineer. The institution has for many years devoted most careful attention to the conditions of training which should be fulfilled by those coming under its purview. The "regular training" prescribed by its by-laws is defined by the council's rules to involve a *minimum* period of three years' pupilage or training as an assistant, where the standard of education is simply that required for admission as a student; and such *minimum* period of practical training may be reduced to two years where a recognised college course of study is taken. In each case the practical training must comprise both experience in the office and in or upon the works.

The institution clearly contemplates a scientific and a practical training for all, and, taking this as a matter of common agreement, the questions to be discussed are: (1) How should the knowledge and experience in each be acquired? (2) Is there any arrangement suitable for all branches of engineering, and if not, what modifications are required for the different branches? (3) Over what period of time should the complete training extend, and what is the best arrangement and division of the time?

Let us look for a moment at the raw material and the finished product, leaving out of account the genius who may achieve eminence in engineering without special training. The raw material is a youth of 17 or 18, fresh from school, educated, perhaps, to a standard below that which might be desired or expected, and supposed to be endowed with common-sense, natural aptitude for the profession, and sufficient physical strength; and the finished product is a blend of scientific and technical knowledge, practical experience, and business method. Our colleges should supply the first two requirements, but I venture to submit that the last two can only properly be acquired in the workshops and offices, and that no training can be considered efficient that does not include a considerable period of practical apprenticeship. Colleges may supply knowledge relating to the properties of materials, the theory and structure of machines, instruction in testing, and in the methods of attacking new problems; but it is only under actual commercial conditions that there can be acquired the proper type of practical experience, adequate knowledge of the design and construction of machines, experience of and sympathy with the workman. It is in the factory or office that there can be gained, by observation and imitation, some knowledge of routine, estimating, organisation and management, business methods and administration, the production of the maximum amount of work with the minimum friction and at the minimum cost. Imitation of good example

* Paper read before the Engineering Conference of the Institution of Civil Engineers.

Digitized by Google

counts for much in engineering as in other professions, and to this, no doubt, can be largely traced the continuance of the success of our national engineering, despite our comparative slowness in advancing with the times. It is in this respect that Continental and American systems of training will be found deficient. There the young engineer is launched into his future occupation after a college training of four or five years with workshop experience gained, especially in America, only in the college, and with sometimes a total commercial experience of a year or less.

It is seldom that a youth when he enters the profession knows what special line he will eventually follow. The organisation of this engineering conference indicates at least seven important branches of the profession. He may be trained as a mechanical engineer and eventually end as a railway engineer, an electrical engineer, or a naval architect. There is no broad line of distinction, the branches being so closely related. The mechanical engineer must not build machines without considering the purposes for which they are intended. The dynamo manufacturer cannot look at a combined set solely from the commutator or collector end; the railway engineer cannot confine his knowledge to the finished girder or the finished locomotive, and the naval architect is not concerned simply with the lines or hull of a ship.

Underlying all branches there is to some extent the same practical foundation. All demand knowledge of the properties and uses of materials of construction, and of the methods and processes by which they are converted into structures and machines. In many of the branches it is generally realised that a man must go through the "shop," and after all, the processes in one "shop" do not greatly differ from those in another. Workshop experience is not, however, generally included in the training of all engineers, but surely it is desirable for all, and especially and increasingly so when steel has displaced to a large extent masonry and timber, when all types of motors bulk largely in their work, and when machines of all kinds are utilised to construct to their designs. If it is considered desirable that the training of all engineers should include experience in suitable workshops and factories, specialisation being confined more or less to the drawing office, the question under discussion is limited to the consideration of the time required, and the best division of that time between the college and the workshop. The duration of training depends to some extent upon the arrangement of the course; but probably it may be safely said that to produce the ideal young engineer the training should extend over five or six years, which might be about equally divided between the college and the workshop. Is there any one system that is the most desirable? I leave it to discussion chiefly by engineers in practice, as I feel certain that the colleges are anxious to have a solution of this problem, and to adapt their courses to any scheme or schemes that may be thought desirable.

In this country at the present time the systems in operation might be classed as (*a*) 1 and 2, "separate" systems; (*b*) 3 and 4, "combined" systems; (*c*) 5 and 6, "compromises."

1 *Workshop only.*—This is a survival of the old traditions. It demands physical exertion during the day and mental strain at night if theory is to be acquired. Many eminent men in the past have undergone the strain and emerged successfully, but in the future the ever-increasing demand upon the engineer will render it unpractical, and almost impossible. Many clever youths enter the shops on this system with limited opportunites but with great ability, and provision should be made for them in any scheme of training.

2. *College only.*—This has already been alluded to. Under exceptional circumstances, such as obtain in the United States, it may be expedient, but it is undesirable.

2. *Works before College.*—A youth entering college after, say, three years in the factory and office is in many respects a good type of student He has gone through the shops at the receptive and imitative age; he has ascertained whether engineering is still to his liking, and comes to college with a knowledge of processes, materials, and machinery. He has some idea of what he wants to know and what branch he wishes to enter, but has often wrong theories which are difficult to uproot. Teachers prefer this type, provided he has continued his studies during his apprenticeship, but this is not always or even generally the case. The youth may have forgotten much of his school training, and, what is worse, he may have forgotten how to study. If he has studied, it is under trying conditions, when he is physically tired, and he may wish to confine his studies to the more interesting technical subjects, the science underlying them being more or less neglected, and in consequence his progress is less rapid. He comes to college probably disinclined to begin again and gain the scientific knowledge which ought to precede all its applications.

4. *College before Works.*—A youth fresh from school and sufficiently educated is likely to make good progress in his scientific studies. In the technical work he is handicapped by his want of knowledge of manufacturing processes and the operation of machines, and is unable to associate his theoretical studies with practical examples of which he has had experience. Laboratories help to some extent to reduce the handicap. If this was to be the standard training there would be a greater plea for college workshops, which would supply some little practical experience, but which could not supplant, even partially, the workshop training under commercial conditions. Some may urge that this system produces a man disinclined to undergo what he calls the "drudgery" of the workshops, but others will be as ready to admit that the proper type of youth acquires his practical experience at a much more rapid rate after he has undergone a college training, and has no such disinclination. This system may be preferred by employers as distinguished from system (2), which may be preferred by teachers.

Other systems are in vogue, either by accident or design, whose object is to avoid the disadvantages connected with "separate" and "combined" systems, or to minimise the required period of training.

5. *Intermittent Systems.*—These include the works-college-works and the college-works-college systems. Many arguments can be advanced by the advocates of each. The first arrangement has to a lesser extent the disadvantages attached to system (3), and the latter system those of system (4). Both waste time, in so far as the usual college terms extend over only nine months of the year, and the remaining three months may be wasted, as few engineers care to take youths for three months in the year; but probably, on the whole, this system is preferable to (3) or (4). In the college-works-college system the youth fresh from school has an opportunity of acquiring a foundation of science on which to rest his works' experience, but if study is not continued his knowledge may evaporate in the works, and at the end of his training he is out of touch with his employers.

6. *Sandwich System.*—This system goes one step further. During a period of, say, five years' training, for four years, six months of each year are spent in the factory or office and six months in the workshops, and the additional year is spent in the workshops or office. It lessens the discontinuity between the two parts of the training, and effects a saving of time, inasmuch as the college long vacations are utilised. An objection which may be put forward is that the youth is always "on the move." He has no time to settle down to either the workshop or college work, and he may have difficulty and extra expense in arranging for lodgings. It must not be forgotten, however, that each part of his work forms a recreation for the other, and the student is likely to return to each with considerable keenness.

7. *Concurrent Systems.*—These either give time for study in classes in connection with workshops, or offer workshop training in connection with college. Both systems have already been alluded to. The objections to (1) and (2) may be applied here. Time taken off the workshops for study gives less time for the practical experience, and this is not acquired under strictly commercial conditions. Except in the very largest works, it is impossible to provide the requisite standard of teachers, and if it is necessary that the youth should breathe the atmosphere of the shops, probably it is perhaps equally necessary for him to breathe the atmosphere of the college.

The list may not comprise all the systems in vogue, and

Digitized by Google

the arguments for and against them are merely indicated, but it serves to emphasise the diversity of the ways in which a youth may enter engineering. Is it not possible, at least to some extent, to standardise the training?

DISCUSSION.

Mr. Drummond, in opening the discussion, said that the system adopted on the London and South-Western Railway at Nine Elms was to take away from school a boy at the age of 15 or 16, give him three years' workshop training, and allow him to go to a class on three mornings in each week.

A lengthy discussion took place, and **Mr. A. F. Yarrow** (Poplar) was warmly applauded on rising to speak. He said that all those who had travelled abroad and concerned themselves in the training of engineers must be struck with the "chaotic state" in which the training here was carried on, as there seemed to be no system or policy. He thought it must be taken as admitted that for a man to occupy a leading position in an industrial undertaking, such as head of an engineering establishment, he must combine scientific knowledge with workshop experience. The question, therefore, arose as to which was the best system to adopt. Of late much attention had been paid to the subject, and they were in a position to form an opinion as to the comparative merits of the different systems, and possibly arrive at some plan which might be deemed the best, and perhaps better than that adopted elsewhere. He thought Prof. Cormack had made it quite clear that he was not dealing with the apprentice who desired simply to learn one branch of engineering, but with the young man who desired to attain a high position in his profession. That involved a more or less expensive education, but mechanics' sons, in consequence of scholarships which county councils and others had placed within their reach, had now an opportunity of pushing themselves to the front and securing an equally good training to that obtainable by those endowed with sufficient wealth. In any scheme that was adopted care should be taken to provide that the sons of poor men, so far as was practicable, were not shut out from the best educational advantages, otherwise the country would be deprived of the ability of the majority. It was desirable to select such a system as might be acceptable to the more industrious and the brighter lads. That was why he was such a strong advocate that all young men, during the period of serving their time in the shops, should start at six. In some works it had been attempted, with more or less success, to have a scientific course in connection with the works. That might be done in very large establishments, but it was evident that any such system would not give a young man the educational advantages that could be found at a universaity or technical school, where the most able professors were found and where various descriptions of apparatus to illustrate principles were available. He felt satisfied that to get the very best scientific training it was necessary to study in one of the leading colleges under the very best teachers. This could be done by a course of three years at a college, and it could be combined with workshop practice by three years in a workshop, either before or afterwards. It was the opinion of the majority of educational authorities that if the scientific and practical work could be proceeded with as far as possible side by side, it would be very much better than completing the one course of study and then taking up the other. They found very frequently in the universities and technical colleges large workshops, which he ventured to say was very undesirable, for he thought the use of machines should be learnt under "commercial conditions," because not only was the use of tools being acquired in the workshops, but the knowledge of the administration of works. He was strongly of opinion that money expended in increasing the number of workshops of technical colleges would be more wisely spent in other directions. The "sandwich" system seemed to offer many advantages for two classes of knowledge where acquired simultaneously. He thought they were very much indebted to Prof. Cormack for bringing it forward in so able a manner.

There was a great diversity of opinion as to what system should be used, some speakers objecting to any cut-and-dried system.

Sir Wm. White said they had had a great variety of opinions, some of which had been very strongly expressed. He noticed there was a universal agreement on one or two points; for instance, that no man could be an engineer unless he had had a large practical experience combined with scientific knowledge. How were they going to find some practical method of procedure out of all the diverse systems? There was not a single system mentioned in the paper which had not produced good men. That discussion would form the basis for considering a settled system, which, in any case, could not be made compulsory. It seemed to him that the Institution of Civil Engineers was naturally the body to take the initiative, but he did not suggest at present in what direction that movement should be made. He thought some members would like to know what had been the Admiralty system of training for nearly half a century. It was one of the oldest organised systems of the country, and it was exceedingly little known. It really embraced two stages, which applied distinctly to the training of officers of shipbuilding and engineering departments. The first stage was residence in a college attached to one of the dockyards. The students, for whom there was a competitive entrance examination, were concurrently studying and working in the shops and dockyards. Then there was a process of weeding. If the candidates did not prove capable of taking that training, they did not go further or went on in some other branch of the service; but those who had proved capable of taking the higher training were then passed on to the Naval College at Greenwich, and there the sandwich system prevailed—a certain number of months at colleges and a certain number of months in the dockyards. That system had been applied with complete success, and it was a system that should be placed on record.

A vote of thanks was accorded the author.

THE MANAGEMENT AND WORKING OF BOILERS.

BY HORACE BOOT.

The following is an abstract of Mr. Boot's paper read before the Municipal Electrical Association at Newcastle:

The author commenced by stating that every central-station engineer should be familiar with the construction, management, and the most economical way of working and maintaining steam-boilers in good repair. Nothing is more detrimental to the satisfactory running of a power station than neglect of this department, or leaving the supervision to leading foremen or workmen. There are few, if any, experienced engineers that, at some time or other, have not been short of the steam required owing to something having gone wrong in the boiler-house, which, perhaps, might have been avoided with clean boilers, proper draught, or more reliable boiler fittings. The author explains that the variable load of an electricity works is much more trying to boilers than that of a mill with regular hours of regular load. He advocates a combination of Lancashire and water-tube boilers, the latter being only used at peak load. To keep water-tube boilers in good order, the author recommends the following boiler-house regulations:

1. Never raise steam quickly; take about three hours from lighting up time for a cold boiler to get up steam.
2. Never allow cold air to blow on the front headers by opening the tube doors when the boiler is hot.
3. As soon as 50lb. of steam is showing on the gauge glass, blow down the boiler for a minute by opening the blow-down cock; test the boiler gauge glasses.
4. When letting down steam in a water-tube boiler, repeat No. 3.
5. Every boiler is to be blown down once in 24 hours. The safety valves tried, the gauge glasses tested every eight hours, the high and low water whistle alarms once every seven days. The soot blown and brushed off the tubes every morning. (It may be mentioned here that the fixed blowers usually fitted to water-tube boilers, when set in a battery, have not been found a success for this purpose, but it is very easy to have little doors built and use the ordinary lance cleaning tube. The objection to the fixed blowers has been that they are likely to only clean one portion of the tube, and cause outside corrosion of the tubes due to moisture dripping. For this reason, and their inefficiency, they have been removed from one of the author's boilers, and replaced by the ordinary type of blow-down lance, with inspection holes in its place among the tubes at the top of the boiler.)
6. The boiler is to be fed with water continuously and not intermittently; the regulation of the feed is to be performed by the speed of the feed pump, and not by throttling the boiler feed valves.
7. Before disturbing a banked fire, open the dampers and the cold-air doors on top of the fire in order to get rid of any accumulated gas; when sufficient time has been given to allow this to disperse, the dampers may be partly closed, and the fire raked up in the ordinary manner.
8. Anything abnormal noticed by the stokers to be at once reported to the engineer in charge.

The above are the regulations for keeping the boilers in good working order, and below are the cleaning and inspection regulations:

1. Every three months each boiler is to be carefully inspected inside and out. If necessary, all the front caps are to be taken off, the tubes scurfed, and valves ground in, if leaky.
2. Before taking down a boiler for inspection, about six to ten gallons of paraffin or soda is to be put in, and the boiler simmered for 60 hours, the steam pressure not being allowed to exceed 50lb.
3. On the completion of the above course, the hot water is to be let down gradually and the top caps removed one by one, so that the tubes are scurfed whilst the hot water is in them, in order to prevent the scale getting hard on the tube before the scraper reaches it.
4. After all the tubes have been scurfed, a careful inspection with a vat lamp—*i.e.*, a lamp to go right down the tube—is to be made.
5. Should any tubes look doubtful or not quite normal, they are to be submitted to a pressure test of about four times the working pressure.

The author then describes the apparatus he has designed and patented for testing a single tube *in situ*. This is illustrated in Fig. 1. This apparatus has been at Tunbridge Wells the means of saving tubes which certainly looked as if they ought to have come out, and other tubes which appeared perfect, after being tested, were found to be weak. There is no need to run any risk with doubtful tubes, as in a few minutes the pressure test can be applied, and the tube can be tested up to destruction if desirable. It also enables tubes to be tested up to higher pressures than the drum should be subjected to. The author has known scale in a tube resist 350lb. hydraulic pressure, and yet the moment that scale became loose the tube ripped open, owing to active corrosion taking place beneath the scale. He recommends a record of the dates of replacing tubes in boilers being kept, and such a record he illustrates by Fig. 2. A log of repairs is also advised to be kept. The author has tried various means of scurfing the tubes. On several occasions the tube turbine cleaner has been used, but it takes so long to do its work, and uses so much water, that he is not at all sure whether it is not cheaper in the end to put in a new tube. The importance of keeping the tubes in a water-tube boiler free from scale is shown by the following figures:

Digitized by Google

Scale $\frac{1}{16}$in. thick, requires about 10 per cent. more fuel.
,, $\frac{3}{16}$in. ,, 25 ,, ,,
,, $\frac{1}{8}$in. ,, 125 ,, ,,
to evaporate the same quantity of water.

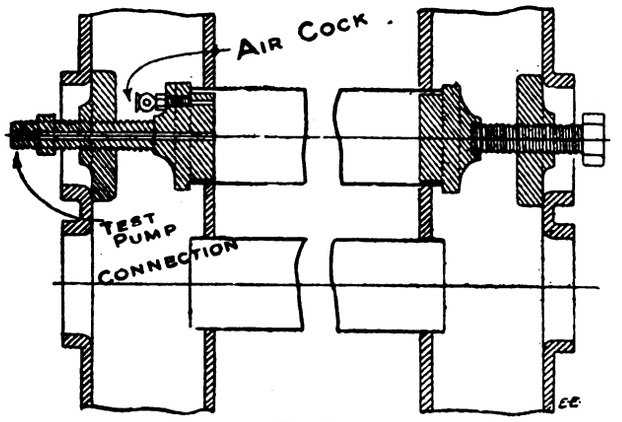

FIG. 1.

The costs of keeping up the five boilers at Tunbridge Wells for 1901 were as follows :

Year 1901.	Boiler I.	Boiler II.	Boiler III.	Boiler IV.	Boiler V.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.	£ s. d.
Scurfing	1 10 1	4 17 0	4 6 8	3 19 6	1 12 3
Brickwork	3 13 6	4 9 0	4 9 0	4 9 0	1 15 0
Cost of renewing tubes	25 4 0	25 4 0	—	—	6 6 0
Labour on ditto	7 18 9	8 0 0	—	—	1 14 7
Firebars, including labour	8 4 0	8 4 0	8 4 0	8 4 0	4 2 0
Repairs to blow-down cocks	0 5 10	0 9 7	0 5 5	—	—
Gauge glasses, rings, and fittings	2 1 0	1 17 0	0 17 0	2 1 0	1 10 0
Total	48 17 2	53 0 7	18 2 1	18 13 6	16 19 10

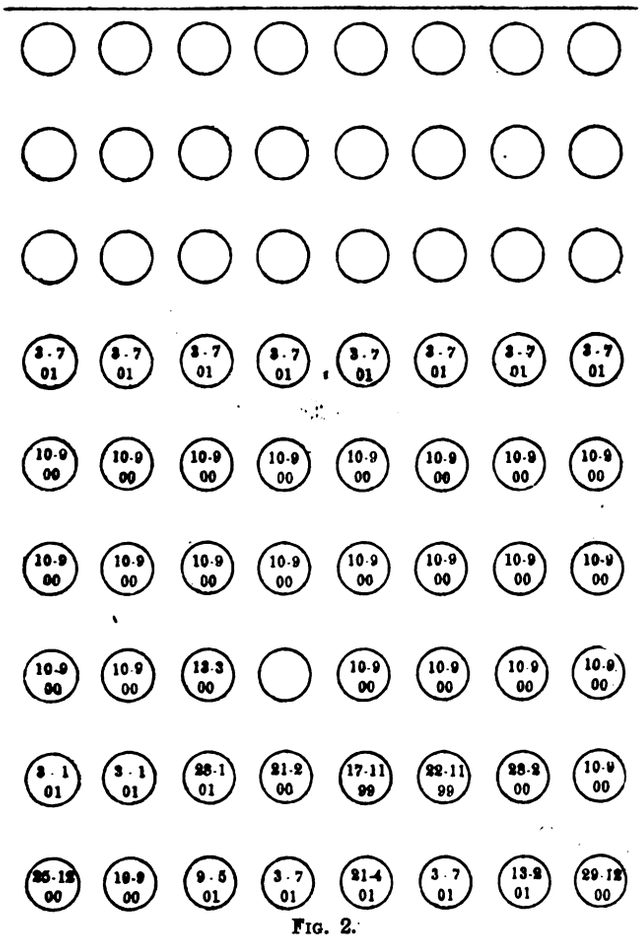

FIG. 2.

The figures for scurfing are not complete, as shift labour is also used for this work. The tube repairs on boilers Nos. 1 and 2 are abnormal, as 24 tubes were renewed in each. The author thinks a fair average with a medium class of water would be 10 tubes per boiler per annum. It has been found that the average cost of renewing a tube, including everything, is 26s. 6d.

It will be noticed that the wear and tear on firebars is high. The cost of the bars is 8s. per cwt. The author has tried all kinds of shaped bars, the air-space between the bars being regulated to suit the various kinds of fuel used. He has found it important to have a flat surface for clinkering, and is now using the dog-tooth bar, originally designed by a Nottingham firm, and from results these bars last longer than the ordinary straight bars, and there is less waste of fuel caused by unburned coal dropping through. The cost per set of ordinary bars was £7 per ton, and of the special design (which lasts half as long again) £8 per ton.

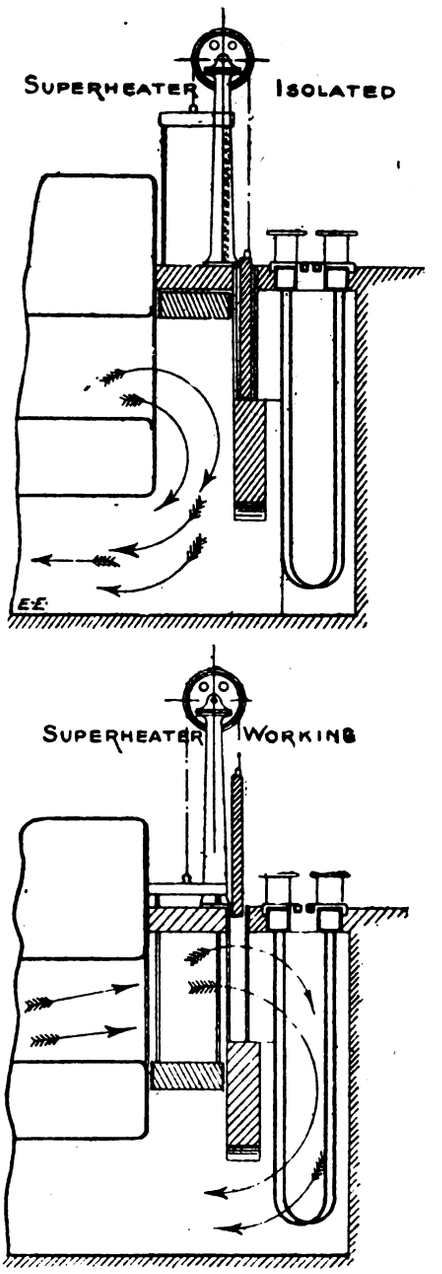

FIG. 3.

The author advises the use of a main isolating valve where several boilers are connected to a main steam range. The valve should be of the "mushroom" type, in preference to the "ball," which latter usually gives trouble when running large engines, owing to its continual knocking, thus damaging its seating. As regards the Lancashire boilers, the author has not found them more economical with regard to coal consumption, and he thinks the radiation losses are more than with the water-tube boilers. He has found the split bridge for the prevention of smoke a most efficient arrangement, although difficulty is experienced in making the stokers use it properly. Below is tabulated the cost of repairs over a period of 12 months to two Lancashire boilers :

	Boiler VI.	Boiler VII.
Brickwork	£1 11 7	£20 15 9
Firebars	5 19 7	6 0 0
Cleaning flues	0 12 1	0 12 0
Caulking seams	1 13 3	0 7 0
Blow-down cock	0 5 3	1 3 6
Repairing dead plates	1 3 8	1 3 6
Miscellaneous details, including labour	4 8 1	2 12 3
Totals	£15 13 6	£32 14 0

Digitized by Google

The author then discusses superheaters, and states that tests at his works show that an economy of about 8 per cent. is obtained by their use. In the author's opinion, a superheater should be constructed and arranged in the flues of Lancashire boilers in such a manner as to comply with the following:

1. The gases must be entirely shut off, and go through a by-pass when the superheater is not in use.
2. It should not be necessary to flood the tubes under any circumstances, flooding being a most dangerous practice, although (unwisely) recommended by certain makers.
3. No cast metal, only boiler plate or forged steel, to be used for the headers or boxes into which the tubes are expanded.
4. Ample provision to be made for expansion and contraction, not only in the construction, but also the method of supporting.
5. Provision to be made for easily renewing defective tubes without an excessive amount of labour.
6. A dead-weight, and not a spring safety valve, to be fitted, of ample size, to relieve any excess pressure, and a lever provided for testing the efficiency of the safety valve from day to day.

It is an easy matter for the superheater flue to be so constructed that if it is desired to cut out the superheater the gases can pass through the by-pass, thus avoiding the necessity for flooding when getting up steam, and of having to withdraw the superheater when there is a defective tube until such be repaired. In Fig. 3 one way of doing this is shown.

In the concluding part of the paper, the author, in justice to boilermakers, states that the feed water at Tunbridge Wells is not desirable in quality, due to the presence of acids. The original water supply has now been abandoned, and the ordinary town water substituted.

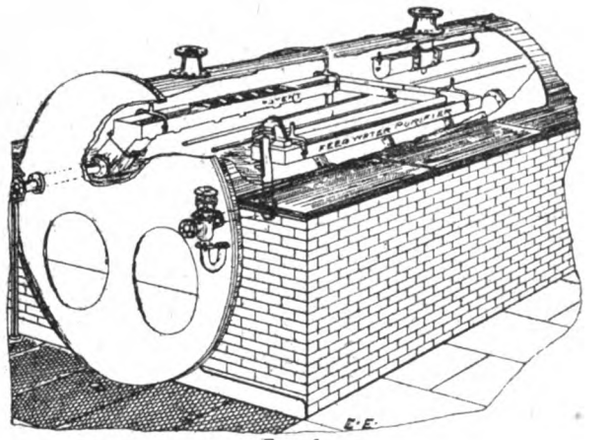

FIG. 4.

For the Lancashire boilers the author has tried a purifier—a sketch of which is given in Fig. 4, from which it will be seen that the comparatively cold water enters the trays, and flows round the steam space of the boiler, returning along the bottom of the zinc plates, dividing the two halves, and when it has deposited all its scale in these trays the water is delivered at *boiler temperature* into the boiler. A separate blow-down cock and pipe are fitted to the end of these trays, and by blowign down every 24 hours the purifier can be used for three montsh without cleaning, but after the boiler had been running three months the deposit was so thick in these trays that they had to be cleaned, because they were choked up.

Mr. T. P. Wilmshurst, of Derby, in opening the discussion, complimented the author on his practical paper. With respect to the renewal of tubes, he noticed that 50 had been renewed in two years. The tubes in the sixth or seventh row should not give any trouble, and he thought the total renewals was excessive. At Derby only the two bottom rows of tubes gave any trouble, and they had had to renew only from four to five tubes per boiler in the course of three years. At Exeter after 14 years' experience no tubes needed renewing. He thought that the lower rows gave out first because they did most work, and in consequence received more deposit. He had found that a chain-grate stoker practically stopped all smoke. It was difficult, however, to keep the fire well covered over the back of the grate at light loads. He had found that for the firebrick arches a much longer life could be obtained by using special key bricks from Stourbridge. These lasted twice as long as ordinary bricks. He thought that analyses should be made regularly of the flue gases, and was installing a carbon dioxide recorder in his station.

Mr. H. Talbot, of Nottingham, said that isolating valves should be used in the steam connections of all types of boilers.

Mr. J. H. Rosenthal, of Messrs. Babcock and Wilcox, pointed out that the water used at Tunbridge Wells contained acid which attacked the boiler tubes. He did not believe in the testing of individual tubes, which was apt to put strains on the headers. A simpler way was to plug the uptake and downtake pipe, and test whole sections together. Mr. Boot's average figure of their renewing 10 tubes per annum per boiler was much too high, and this would be confirmed by other users of the same water-tube boilers. He did not agree with Mr. Boot's remarks on the flooding of superheaters. It was in starting up that the superheaters were apt to be damaged, as then they contained neither water nor steam. As regards the addition of a valve between the boilers and the superheater, he thought the practice dangerous. Mr. Wilmshurst was correct as to the reason for the lower tubes going first. Practical experience, however, had shown that the work could not be equally divided between the tubes, and that if the number of rows was reduced, the boiler did not take the heat from the furnace gases as it should do. In fact, the addition of a superheater in retarding the gases on their way over the tubes improved the efficiency of the boiler. The difficulties of the early make of the chain-grate stoker as regards air leakage has now been got over.

Mr. A. G. Cooper, of Colne, agreed that the lower tubes alone should give trouble. Isolating valves were exceedingly useful if a stop-valve of a boiler was inadvertently opened before its pressure was high enough.

Mr. J. K. Bridges, of Eastbourne, remarked that there were other makes of water-tube boilers than the Babcock-Wilcox. He did not approve of frequent hydraulic testing of the tubes, and his experience of the turbine tube cleaner was much more favourable than the author's. There was no need to use a joint ring with the Babcock-Wilcox boiler, but with the Hornsby boiler they had to be used, and caused trouble. His experience had been that makers would not guarantee mushroom isolating valves with superheated steam.

Mr. Ruthven-Murray, of Willesden, advocated the use of glazed bricks to keep down air leakages through the brickwork. He had found, in consequence, that glazed bricks got hot because their surface did not radiate so well as a roughened surface of ordinary bricks. He also believed in the testing of flue gases regularly. For lagging he preferred a silicate cotton under a metal shield. The air imprisoned in the cotton acted as a good lagging. He thought that the economy from superheating should be considerably more than 8 per cent.

Mr. H. B. Maxwell, of Partick, had used the multiple firebars with satisfaction, both with ordinary boilers and with refuse destructors.

Mr. Robert Quin said that for removing oil a chemical process was the only one. Hydrated ferric oxide would serve, as would also aluminium sulphate. He thought the author's tube-testing arrangement was responsible for the header distortion he had referred to. He advocated gannister firebricks for boiler furnaces.

Mr. L. Robertson, of Hackney, gave a good record of the Babcock-Wilcox water purifier.

Mr. W. A. Vignoles, of Grimsby, advocated the undertype of stoker, which could be made quite smokeless.

Mr. H. L. P. Boot, in reply, said that everything depended on the feed water in the cost of boiler upkeep. He threw doubt on the small cost of repairs and few tube renewals which some engineers claimed. He found that firebrick arches lasted from eight to nine months. In spite of what had been said, he thought that the ordinary expansion and contraction would distort the headers. The Edmiston filter referred to was a marine type. The filtering medium was towel cloth, but the filter had not to deal with any considerable quantity of oil. He had not found much advantage from grouped firebars.

ECCLES ELECTRICITY ACCOUNTS.

Below we give an abstract of the accounts of the Eccles Corporation electric light works for the year ended March 31 last.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	1,438	10	2
Distribution of electricity	316	18	2
Public lamps	76	15	1

CORRESPONDENCE.

WIRELESS FIRE-ALARM.

SIR,—With respect to the note headed "Wireless Fire-Alarms," on p. 187 of your issue of Aug. 8, I beg to offer the following observations on your remarks. I note that you are in favour of electric fire-alarms. Concerning my apparatus you say in the first place, "The most recent development of such an alarm is one patented by Mr. Guarini for doing without communicating wires Experiments in Brussels have shown that the system will work, but we are not hopeful of any system which depends on the Hertzian wave for giving such an alarm." This has need of explanation, because you make in it reproach on all wireless telegraphy by Hertzian waves. In the first place, I would say that I could make my system work equally well with ordinary alternating currents; secondly, I would refer you to the Hertzian-wave systems of Marconi, Slaby-Arco, Braun, De Forrest, Fessenden, Rochefort, etc, which are far from a myth, and which over short distances give perfect satisfaction. If wireless telegraphy over long distances is still open to fault, this does not apply to communications over small distances. I claim that over small distances wireless telegraphy leaves nothing to be desired, and has the following great advantages: it costs less to instal than connections with wires, and, secondly, is exempt from all those inconveniences which accompany overhead wires. It remains, then, to show that communications by wireless telegraphy over short distances are exempt from all those faults which signalling over great distances possess. These latter inconveniences are due to (1) the great sensitiveness which the receiver must have to avoid the employment of large power in the transmitters; (2) the space required for and height of the aerial wires which introduce disturbances due to earth currents and atmospheric electricity. Over small distances the vertical wires are short, and by the employment of condensers, connections with the earth can be avoided. It remains now to see if your remarks on my fire-alarm can be met. You say: "Quite apart from the difficulty of getting good distinctive signals from a large number of subscribers, there is the interference question, which is even more serious in a fire-alarm system than in ordinary telegraphy." The first difficulty can be got over easily in the way that is done with the May-Oatway fire-alarm, by transmitting Morse signals, each subscriber having a different signal. With regard to the interference being more serious, I think you would have to search in vain for two fires which commenced in the same town exactly at the same moment. Even then, by continuing to repeat the alarm, the signals can be divided out. At the end you say: "Up to the present we know of no experiment which gives that secrecy and freedom from interference with wireless telegraphy which can be obtained easily and cheaply when wires are employed." I would remind you that up to 4 km Hertzian reflectors have been employed with success by Marconi, which would be quite sufficient to avoid interference. Also in your issue of Aug. 7 you publish a letter of mine on the same subject. Then, again, by syntony secrecy can be assisted, but in my fire-alarm there is absolutely no necessity to avoid interference, or to take any precautions whatever against it. I freely admit that communications with wires can be easily made, but this is equally the case with wireless telegraphy, and the installation can be made in less time. It also avoids the overhead wires, which are objectionable. I am of the opinion that if one day the conditions laid down by Mr. Oatway are fulfilled completely, it will be done by means of wireless telegraphy.—Yours, etc.,

E. GUARINI.

[We regret to have had to condense the above letter, but think we have given the author's meaning fairly. He does not realise our point, that his wireless fire-alarm station would be receiving at odd times Morse code messages from other wireless telegraph systems in the neighbourhood or from casual experimenters. The essential feature of any system of electric fire-alarms is that it shall be quite distinct and apart from any other system which might give fictitious calls at any time. It is the fear of these fictitious calls, owing to defect in working, which has made the London County Council Fire Brigade refuse to recognise up to the present any automatic electrical fire-alarm system.—ED. *E. E.*]

JUDGING ELECTRICAL FIRE BRIGADE CALLS AT EARL'S COURT.

SIR,—I shall be glad if you will allow me space to call attention to the methods adopted by the executive of the British Fire Prevention Committee (is there such a thing as fire prevention?) in judging the exhibits entered under this class at the International Exhibition at Earl's Court.

My company is an exhibitor, and some time in June delivered at the request of the committee a descriptive schedule of the exhibit, which was acknowledged in due course. Some time subsequently we were notified to take our "hand machines" to the lake for examination by the jury on July 15, just as though the authorities in their wisdom did not know that a system of automatic fire-alarms did not indulge in hand machines, and was not a squirt, a diving bell, or other appliance in need of a lake. However, explanations passed, and in the end, classed as brigade calls, we were notified to be ready for the jury on the 7th inst. The writer came up from Scotland, expecting, as any other reasonable man would expect, that an electrical fire brigade device would be judged by electrical and fire brigade experts, and you can well imagine my surprise at finding the jury composed of two insurance surveyors (one an A.I.E.E.), a borough surveyor, an architect, and the respected chief of the Salvage Corps; but never, oh! never, a practising consulting or working electrician or fire brigade officer amongst them. Never imagining for a moment—original and anxious to glorify its members as the British Fire Prevention Committee is known to be—that that body would dare go to this length, the writer came to the conclusion that the only member of the jury unknown to him was the chief officer of a well-known brigade, and went ahead with the demonstration instead of withdrawing the exhibit from the investigation of such a group. So soon, however, as the identity of the fifth juror became known, and before any awards were made public, a protest was lodged with the executive, and it is to ask your readers to watch the result of this protest that I am now writing. I do not demur in the slightest to the integrity or status of the members of the jury, but just as no one in his senses would ask his Grace of Canterbury to judge the turnips at an agricultural show, or the president of the Royal Society the *lingerie* at Jay's, so the exhibitors in this class have a right to expect that the judges shall combine expert practical knowledge of the subject they are adjudicating upon with the necessary integrity, patience, and attention to detail. No awards are yet known, and I have asked the executive authorities to seek the assistance of the professional fire chiefs and National Fire Brigade Union committees in selecting brigade chiefs and electricians, and leaving them free to include lay members of their own committee, salvage experts, etc., so long as the practical element is in a preponderant majority. It now remains to be seen whether a common-sense suggestion of this kind commends itself to the authorities.—Yours, etc.,

GEO. W. OATWAY.

[We quite agree with Mr. Oatway that committees making awards at exhibitions should be composed of men expert in the branch of science involved.—ED. *E. E.*]

RE N. F. NALDER.

SIR,—Referring to your report of the proceedings under the failure of Noel Francis Nalder, of 19, Queen Victoria street, E.C., some confusion appears to have arisen between the name of the debtor and Mr. Francis Henry Nalder, one of our managing directors. We shall esteem it a favour, therefore, if you will kindly note in your next issue that our Mr. Francis Henry Nalder has not, nor ever has had, any connection, direct or indirect, whatsoever with Mr. Noel Francis Nalder, nor has he or our company of Nalder Bros. and Thompson, Limited, ever had any connection with any of the companies in which Mr. Noel Francis Nalder was interested.—Yours, etc.,

NALDER BROS. AND THOMPSON, LIMITED.
(E. Thompson, Managing Director.)

MUNICIPAL TRADING.

In our last issue we noticed briefly that a report by the joint committee appointed to consider this question had been published. The order of reference must be examined before any conclusion can be reached as to the value of the report. It was practically to "consider and report as to the principles which should govern powers given by Bills and provisional orders to municipal and other local authorities for industrial enterprise within or without the area of their jurisdiction." In 1900 a similar joint committee sat upon a similar order of reference. The 1903 committee in its report says of the 1900 committee:

"In consequence, however, of the great extent of ground to be covered, and the complexity of the subject, that committee were unable to make any report on the merits, but confined themselves to a recommendation of reappointment in the next session."

This proves that in 1900 there was no report on the merits of the case, nor is there in the present report one scrap of decision upon these merits, for paragraph 7 of the report says:

"Whatever view may be taken of the proper limits, if any, which can be set to municipal trading, it is clearly important that wherever it exists ratepayers should be not less fully and continuously informed of the success or failure of each undertaking than if they were shareholders in an ordinary trading company."

The importance of keeping a true and correct set of accounts admits of no discussion, but what has this to do with the merits or the limits of municipal trading? The fact is that the committee has deliberately ignored the order of reference, and spent its time and the public money upon a question of detail which did not concern it and with which it had nothing to do. What are the principles, and what are the limits, if any, that underlie municipal trading? These are the questions asked in the order of reference, but they are not answered in the report, nor has the committee taken any evidence that would assist in solving the questions. The whole thing has been a grotesque farce, and the result contemptible inanity. Reading between the lines, we come to the conclusion that neither the Government nor the committee care to tackle the main question. Tacitly they assume "What is, is right," that municipal trading exists and will continue to exist, that limits or principles are to be ignored, but some few petty suggestions about details may be embodied in a Bill. If that is done, the Government will have flouted the business men interested in the question, and the interference will irritate the municipal people, while doing no good. Either municipal trading is wholly good or wholly bad, or good within limits. There are few readers, or rather students, of history nowadays, otherwise it would be better known that municipal control of trading had been tried and failed. The current report deals mainly with the due keeping of accounts and having a proper audit, with a tail piece stating the advisability of continuing the investigation "into other branches of the subject." Here, again, we see inferentially the assumption that municipal trading has come to stay. The logic is, municipal trading exists; why trouble to enquire into the rights and wrongs of its existence? Just so, thieving exists; why enquire into the rights and wrongs of thieving? The present position of the matter is simple. Municipalities want to take all the plums of trading, and anybody can have the competitive trade. The plums are everything of the nature of a monopoly—no competition, and, therefore, little incentive to progress. Private enterprise may invent and improve. If

Digitized by Google

it trades competitively, it must adopt the latest improvements in order to exist. The municipality, on the contrary, exists anyhow, and may or may not be "up to date." At the present moment, no doubt, the municipalities have done and are doing good work, and their concerns are mostly very up to date; but that is because the days are young. By-and-by, when fluctuations in business come, as they will and must come, what will be the position of a town heavily in debt, heavily rated, and retrogressing? We think its downfall will be hastened because of its being in business. It is a great pity that the Government and the committees have not had courage enough to make a thorough enquiry and give definite opinions. One word as to accounts. The report is to all intents and purposes a report condemning the accounts of local authorities, and, in our opinion, this is an absolutely incorrect view of the matter. The accounts of the local authorities on the whole are better kept, more in detail, and more understandable than those of companies. In the prominent cases which have led to complaint the items under controversy have been items that might with equal correctness be placed under either of one or two headings. We have never found any disposition by a local authority to falsify the exact final position of its financial affairs, though there have been differences of opinion as to how items should preferably be charged. The electors elect representatives upon the councils. Surely these men, who pay the money to be expended, are interested enough to see that their representatives are neither thieves nor rogues. This report infers that dishonesty is rampant, which we assert deliberately is wrong. Are mayors dishonest? Are they, usually the loyalist of loyal citizens, likely to nominate inefficient auditors, or auditors who will scamp their work? The report says little interest is taken by the ratepayers. Admit it. What does it mean but that those who do take an interest will see that the men elected are men who will take an interest in their work also? Altogether, in our opinion, a more contemptible report was never issued by a committee since this world began. It has left everything undone which it ought to have done, and done nothing it ought to have done.

THE PARIS METROPOLITAN RAILWAY DISASTER.

Our readers will have learned from the daily Press most of the details of the disastrous fire on the Metropolitan Railway of Paris on Monday last in which 84 passengers lost their lives. The following account may help to fix what little technical information is now available, and help in the formation of a just opinion as to how far such a fire is preventable. The stationmaster at the Rue des Couronnes Station is responsible for the statement in the *Daily Telegraph*, that "train No. 43, coming from the Porte Dauphine, and bound for the Place de la Nation, had been brought to a standstill at the Boulevard Barbes Station, owing to a mishap to the engine. The passengers were directed to leave the train. Train 52, following at a short distance, was also vacated, and was used to push on No. 43. The two trains ran through the Chapelle, Rue d'Allemagne, Rue d'Aubervilliers, Place du Combat, and Belleville Stations without stopping, so as to clear the line. When they passed the Rue des Coronnes Station flames were perceived at the bottom and up the sides of the cars. I cried to the guards who were standing at the open doors of the passing train, 'Stop, you will never reach the next station.' 'All right, all right,' the driver called back. 'We will get there safely,' and the two trains, already afire, disappeared at a terrific speed into the tunnel. Just before they reached the next station, that of Ménilmontant, a flame suddenly flashed out between the leading motor carriage and the car behind, and a violent explosion was heard. In a second flames enveloped all the eight cars of the two trains. The drivers and guards just had time to fly for their lives. The flames rose up to the roof of the tunnel and licked its sides. The electric light wires were melted and the whole tunnel was plunged in darkness, except for the glow of the conflagration. The current was immediately switched off, and train 48, which was coming up behind, stopped 300 yards before the Rue des Couronnes Station. A terrible panic occurred among the passengers of the train. Some rushed back to the Belleville Station, others went on to the Rue des Couronnes through the suffocating smoke and the luridly-lit darkness."

From this and other accounts it appears that the passengers in No. 48 train were never near the burning trains, but that in walking towards the Rue des Couronnes Station or in the station itself they were suffocated with smoke.

Naturally, the public wish to know if electric trains and electric railways are specially liable to the above type of accident. We would point out that from the above the following conclusions are derivable:

(*a*) That the locomotive on train No 43 was defective, and that it commenced the fire.

(*b*) That, instead of extinguishing the same, as could easily be done at first, the train was pushed over six sections and halfway over the seventh at express speed (over two miles of which the first portion was above ground).

(*c*) That this caused the flames to spread from the leading locomotive, which was defective, right down the two trains, and that the insulation round the conductors in the leading locomotive carriage was destroyed.

(*d*) That further short-circuiting then occurred, which apparently cut off the current from that section of the railway.

(*e*) The drivers then abandoned the trains, which they had so thoroughly set on fire, and saved themselves.

We have no wish to attribute blame to these drivers or to the officials, but trust that a full enquiry will be made as to the person responsible for the order to push a burning train over lines which were being used by the public. It must be remembered that the Paris Metropolitan Railway has two lines in one tunnel, or in cut and cover, and it is rather curious that more loss of life did not occur from the fire being conveyed to trains on the other parallel line. Considered with the Liverpool accident, the above tends to a general conclusion that no employé should be allowed to move a train, after defects have been found in the locomotive circuits, until every trace of fire has been put out. Also that independent lighting circuits should be used, so that short-circuits on the power mains will not throw both tunnels and stations into darkness. It was clearly sheer error in management which turned a trivial defect into a great disaster. The same error would have produced the same results with any system of driving.

REPORT ON MUNICIPAL TRADING.

The order of reference to the Joint Committee was practically to "consider and report as to the principles which should govern powers given by Bills and provisional orders to municipal and other local authorities for industrial enterprise within or without the area of their jurisdiction, and request that this House appoint an equal number of lords to be joined with the members of their House." And this is the report:

The Select Committee appointed to join with a Committee of the House of Commons to consider and report as to the principles which should govern powers given by Bills and provisional orders to municipal and other local authorities for industrial enterprise within or without the area of their jurisdiction. Ordered to report: that the committee have met and examined witnesses, and have agreed to the following report:

1. The present committee may be regarded as continuing the enquiry held by the Joint Committee on

Digitized by Google

Municipal Trading appointed in 1900, an identical reference having been made in each case.

2. The evidence taken by the former committee was of a general character, beginning with a detailed examination of the limits and restrictions now imposed upon the undertakings of local authorities by different departments of State, by the authorities of both Houses entrusted with the regulation of private business, and by the practice of select committees. The former committee then proceeded to some consideration of the general arguments advanced by advocates and opponents of municipal trading.

3. In consequence, however, of the great extent of ground to be covered, and the complexity of the subject, that committee were unable to make any report on the merits, but confined themselves to a recommendation of reappointment in the next session.

4. The present committee, in view of the fact that they were not appointed until after Whitsuntide, and were unable to hold their first meeting before June 15, decided to take a different course.

5. The committee felt that any attempt to survey the general subject of municipal trading could only have led to a second postponement of the enquiry, as it would have been impossible for them in the short time available before the close of the session (when the existence of every committee is terminated) to issue a report upon the whole subject. They agreed, therefore, to devote their attention to one or more distinct aspects of the question, passing by others until Parliament should be pleased to direct further enquiry.

6. The first branch of the subject with which the committee decided to deal was that of municipal accounts, with regard both to the form in which they are prepared, the systems under which they are audited, and the right of access to them possessed by the ratepayers. The evidence taken has been mainly directed to these questions.

7. Whatever view may be taken of the proper limits, if any, which can be set to municipal trading, it is clearly important that wherever it exists ratepayers should be not less fully and continuously informed of the success or failure of each undertaking than if they were shareholders in an ordinary trading company.

8 In a large number of cases this is undoubtedly done. But there is in some instances evidence to a contrary effect, and in view of the ever-increasing number and magnitude of municipal undertakings, it is most desirable that a high and uniform standard of account-keeping should prevail throughout the country.

9. The committee are doubtful whether it would be possible to prescribe a standard form of keeping accounts for all municipal or other local authorities, having regard to the varying conditions existing in different districts. But they recommend that the Local Government departments should invite the Institute of Chartered Accountants, the Incorporated Society of Accountants and Auditors, and the Institute of Municipal Treasurers and Accountants of England and Wales, and the Society of Accountants in Edinburgh, and the Scottish Institute of Accountants, Glasgow, to confer and report upon the matter.

10. The committee have directed full attention to the question of audit.

11. The committee recommend that a uniform system of audit should be applied to all the major local authorities—viz., the councils of counties, cities, towns, burghs, and of urban districts.

12. At present municipal corporations in England and Wales, with a few exceptions, are only subject as regards audit to the provisions of the Municipal Corporations Act, 1882, by which one auditor, who must be a member of the town council, is nominated by the mayor, and two, who cannot be members of the town council, are elected by the ratepayers.

13. The evidence shows that no effective system of audit is thus supplied. The elective auditors are poorly paid, or are unpaid altogether, little interest is taken in their election, and although in some cases they are able to lay a finger on a particular irregularity, it is not clear that they could not make the same discovery in the capacity of active ratepayers. No complete or continuous audit is ever attempted by them.

14. All county councils, the London borough councils, and urban district councils are subject to the Local Government Board audit. This audit is carried out by district auditors, who as a rule are not accountants, and are not, in the opinion of the committee, properly qualified to discharge the duties which should devolve upon them. By special local Acts the Corporations of Tunbridge Wells, Bournemouth, and Southend-on-Sea must, and the Corporation of Folkestone may, adopt the Local Government Board system of audit. The duties of the auditors seem to be practically confined to certification of figures, and to the noting of illegal items of expenditure.

15. To apply this system of audit to municipal corporations would arouse strenuous opposition from them, and the course may be considered impracticable; but in addition to this the fact that district auditors are not accountants seems to unfit them as a class for the continuous and complicated task of auditing the accounts of what are really great commercial businesses.

16. The committee accordingly recommend that: (*a*) the existing systems of audit applicable to corporations, county councils, and urban district councils in England and Wales be abolished; (*b*) auditors, being members of the Institute of Chartered Accountants or of the Incorporated Society of Accountants and Auditors, should be appointed by the three classes of local authorities just mentioned; (*c*) in every case the appointment should be subject to the approval of the Local Government Board, after hearing any objections made by ratepayers, and the auditor, who should hold office for a term not exceeding five years, should be eligible for re-appointment, and should not be dismissed by the local authority without the sanction of the Board; (*d*) in the event of any disagreement between the local authority and the auditor as to his remuneration, the Local Government Board should have power to determine the matter; (*e*) the Scots practice of appointing auditors from a distance, in preference to local men, to audit the accounts of small burghs should in similar cases be adopted in England.

17. The committee are of opinion that it should be made clear by statute or regulation that the duties of those entrusted with the audit of local accounts are not confined to mere certification of figures. They therefore further recommend that (*a*) the auditor should have the right of access to all such papers, books, accounts, vouchers, sanctions for loans, and so forth as are necessary for his examination and certificate; (*b*) he should be entitled to require from officers of the authority such information and explanation as may be necessary for the performance of his duties; (*c*) he should certify (i.) that he has found the accounts in order, or otherwise, as the case may be; (ii.) that separate accounts of all trading undertakings have been kept, and that every charge which each ought to bear has been duly debited; (iii.) that in his opinion the accounts issued present a true and correct view of the transactions and results of trading (if any), for the period under investigation; (iv.) that due provision has been made out of revenue for the repayment of loans, that all items of receipts and expenditure and all known liabilities have been brought into account, and that the value of all assets has in all cases been fairly stated.

18. Auditors should be required to express an opinion upon the necessity of reserve funds, of amounts set aside to meet depreciation and obsolescence of plant in addition to the statutory sinking funds, and of the adequacy of such amounts.

19. The auditor should also be required to present a report to the local authority. Such report should include observations upon any matters as to which he has not been satisfied, or in which his judgment called for special notice, particularly with regard to the value of any assets taken into account.

20. The local authority should forward to the Local Government Board both the detailed accounts and the report of the auditor made upon them. It should be the duty of the auditor to report independently to the Board any case in which an authority declines to carry out any recommendation made by him.

21. A printed copy of the accounts, with the certificate and report of the auditor thereon should be supplied by

Digitized by Google

the local authority to any ratepayer at a reasonable charge.

22. After careful consideration, the committee are of opinion that, in view of the thoroughness of the proposed audit, powers of surcharge and disallowance could be altogether dispensed with in the case of the major local authorities.

23. Those powers could not, it is believed, be applied to municipal corporations, in view of the strong objection expressed by them; and it is doubted whether their retention in the case of other authorities would compensate for the loss of uniformity which would result.

24. The power of disallowance, applying as it does only to illegal expenditure, and not to unwise undertakings and enterprises, does not afford any real safeguard to the ratepayers whose interests are affected.

25. With a continuous, vigilant, and thoroughly efficient system of inspection and audit, the surest guarantee to the ratepayers against extravagance is to be found in the deterrent effect of public exposure, in addition to the existing legal remedies.

26. The dispensing power possessed by the Local Government Board under the Local Authorities (Expenses) Act, 1887, throws on the department an amount of work often out of proportion to the importance of the issue involved.

27. The committee suggest that, in view of the large changes recommended by them, it might be advisable to create a new body, in the form of a Board of Commissioners of Local Audit, in some respects analogous to the Railway Commission. This body could be entrusted with the powers which the committee recommend in their report should be vested in the Local Government Board.

28. The committee recommend that if in the case of Scotland it is thought desirable that the existing statutory audit of accounts of county and borough councils should be maintained, at any rate the system of audit for the five large cities, which is at present regulated by private Acts, should be assimilated to that which is recommended for the major local authorities in England.

29. The committee are of opinion that it would be advisable to continue investigation into other branches of the subject of municipal trading in a future session of Parliament.

FORTHCOMING EVENTS.

Iron and Steel Institute.—Summer meeting, Barrow-in-Furness, September 1-4.

Institution of Civil Engineers.—Birmingham Students' visit: September to Rhayader.

Municipal and County Engineers.—Meetings: Aberdeen, Aug. 20, 21, and 22; Hastings, September 11 and 12.

Junior Institution of Engineers.—Summer meeting at Sheffield, Aug. 17 to 22. The proceedings will be opened at the Town Hall at 11 a.m., when the Lord Mayor of Sheffield will welcome the members.

British Association.—Seventy-third annual meeting, September 9, Southport.

APPOINTMENTS VACANT.

Chief Assistant Engineers, Hull Corporation, £200 per annum. See advertisement.—Ipswich, salary to commence at £160 per annum. See advertisement in last issue.

Assistant Electrical Engineer, Londonderry, £130 per annum. See advertisement.

Electrical Engineer, Hunslet Guardians, Leeds, Aug. 17.

Lecturer, Hull Municipal Technical School, £150 per annum. See advertisement.

Mains Superintendent, Bury, £120, rising to £150 per annum. See advertisement.

Pupil or Junior Draughtsman. See advertisement.

Canvassers. See advertisement.

Three Charge Engineers, Ipswich, salary to commence at £90 per annum. See advertisement in last issue.

Two Switchboard Attendants, Ipswich, salary to commence at £60 per annum. See advertisement in last issue.

Instructor in Mathematics, Governing Body of the Northampton Institute, Aug. 24.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

609. Can anyone tell me which is the best contact breaker to use on a medical induction coil, giving their reasons for thinking so?—J. S.

610. Show diagrammatically the simplest method of controlling a single incandescent lamp from three places independently. Also give a sketch of the switches used for the purpose.—R. H. G.

ANSWERS.

Question No. 601.—It is desired to add condensing plant to an electric light station. It is proposed to draw the circulating water from the sea, which is at hand and is 25ft. below level of condenser at low water, by means of a pair of suction pumps. What precautions must be taken in putting down the pumps and piping? Is it the case that a U-bend in the pipe interferes appreciably with the suction?

Best Answer to No. 601 (*awarded* 10*s.*).—It is found in practice that 25ft. is too much for a suction pump to give a reliable performance. The best possible conditions can be readily calculated. We may take the weight of one cubic foot of sea-water as 64lb. and the barometric pressure as 14lb. per square inch. Although the average pressure of the atmosphere is about 14·75lb. per square inch, allowance must be made for the lowest depressions. Pressure due to the column of water in the suction pipe must be exactly equal to the barometric pressure. If x = height of the column of water in feet,

$$x \times 64 = 14 \times 144\,; \quad \therefore x = 31{\cdot}5.$$

This, however, gives the height when the vacuum is perfect, and to obtain this by means of a pump is utterly impossible. To take an example, suppose the stroke of the plunger is 9in., and that it has a clearance of 2in.

$$\frac{\frac{1}{6}}{\frac{3}{4}+\frac{1}{6}} = \frac{\frac{1}{6}}{\frac{11}{12}} = \frac{2}{11}\,;$$

that is, the air in the space of 2in. has filled 11in., and, therefore, exerts a pressure equal to $\frac{2}{11}$ of that due to the atmosphere. This must obviously be subtracted from our supposed pressure of 14lb.—31·5 − ($\frac{2}{11}$ of 31·5) = 25·8. By having a longer stroke for the plunger and reducing the clearance, these figures would be improved; it is, however, found impossible in practice to obtain such results, owing to the difficulty in keeping glands, joints, etc., airtight. Fifteen feet is a very usual limit for a suction pump in general work. If it should be decided to employ suction pumps, it will be well to have them fixed 8ft. or 10ft. below the level of the condenser; this will entail expense at first, but will greatly reduce trouble afterwards. Any bends, elbows, etc., in the suction pipe are detrimental, owing to the increased friction. This will be the more noticeable if the pumps are run at a high speed. If the U-bend gave any possible danger of air-locking, this would be another source of trouble. By all means let the suction pipes be large enough and be as straight as possible.—M. M.

Answer to No. 601 (*awarded* 5*s.*).—In laying down the proposed condensing plant, precaution should be taken to have the suction pipe for circulating water as straight as possible, as the effect of contour of pipes on the flow of water is important. It would appear from the query that it is necessary to have a bend in this pipe to pass some obstruction; if such be the case, care should be taken that no portion of the pipe rises above the hydraulic mean

Digitized by Google

gradient. In Fig 1 an imaginary diagram shows the level of suction entry to pump, and the inlet end of suction pipe in the sea. If these are set out with the proper lineal distance and height to scale, a line drawn between the two points will give the hydraulic mean gradient, *a d* (Fig. 1).

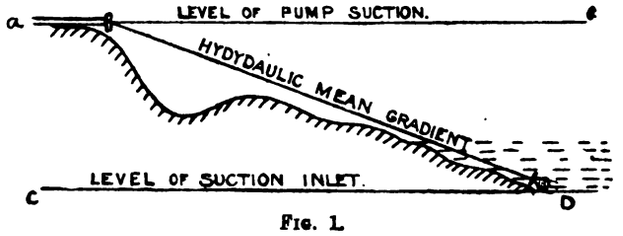

FIG. 1.

In this diagram the contour of the land is all below the mean gradient line, and the suction pipes may follow this contour without any loss of effect, but in Fig. 2 it will be observed that the portion of the contour, *a*, *b*, *c*, is above the mean gradient line, and a suction pipe following this contour would lose much in effect. The water flowing from *b* to *a* would cause a partial vacuum at *b*, and the air held in solution by the water would be liberated and would accumulate in the portion of the pipe *a* to *b*, causing a loss of suction.

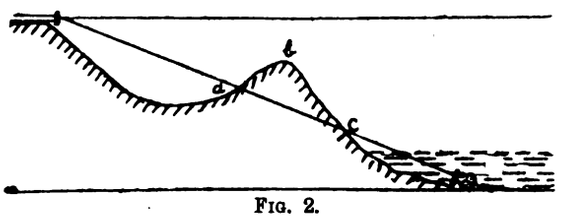

FIG. 2.

The worst arrangement of suction pipes is shown in Fig. 3, where the suction pipe not only rises above the hydraulic mean gradient, but also above the line of pump suction branch. This arrangement should be avoided if at all possible, but if really unavoidable, an air-vessel should be placed at the highest point of the suction pipe, with means for drawing off the accumulated air at intervals.

Precaution should also be taken that the suction pipes are of sufficient area not to cause undue loss by friction. It is not safe to take the size of suction branch as a guide for this, as pump-makers often calculate the suction diameter on the supposition of a short lift, and omit friction loss. The diameter of pipe required for a flow of a given quantity of water may be obtained by use of the formula—

$$d = \left(\frac{G^2 \times L}{H}\right)^{\frac{1}{5}} \div 3,$$

where d = diameter of pipe in inches;
G = gallons per minute;
L = length of suction pipe in yards;
H = height of suction lift in feet (head of water in feet).

It should be remembered, however, that the flow of water from and to a pump is not uniform in quantity and velocity owing to the intermittent action of the pump, and allowance should be made for this variation in calculating the size of the pipes required. The following table from Box's "Hydraulics" will serve to show the variation in flow from different classes of pumps:

TABLE OF VELOCITY OF DISCHARGE BY PUMPS WITHOUT AIR-VESSELS.

—	Velocity of discharge. Max.	Mean	Min.	Variation per cent.
One single-acting pump, worked by a crank	314·16	100	000	314·16
Two ditto, worked by cranks at right angles	222·00	100	000	222·00
One double-acting pump	157·08	100	000	157·08
Three-throw single-acting	104·76	100	90·69	14·07
Four single-acting or two double-acting	111·00	100	78·79	32·21

An air-vessel would partially equalise the flow of water, and one should be fitted at the highest part of the suction pipe, and near to the pump. The inlet, or sea end of the pipe, should be fitted with a retaining valve to prevent air accumulating in the suction pipe. If the level of the pump could be lowered without introducing the conditions shown in Fig. 3, it would be advantageous, as 25ft. is a deep lift, and would require the pump to be kept in thorough good

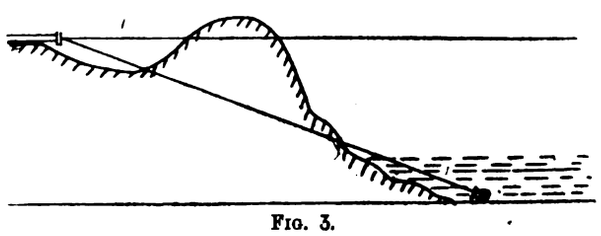

FIG. 3.

repair to maintain it. The condenser should have the cooling surface sufficiently large that the circulating water is not raised in temperature to the point at which it will precipitate salt, or the condenser will prove troublesome from scale formation.—STOW.

Answer to No. 601 (*awarded* 5*s.*).—A much fuller discussion of this question would have been possible had "D. R." given a few more details, such as the types of condensers and pumps proposed, the approximate amount of steam to be condensed per hour, etc. As the available supply of condensing water is plentiful, the choice of condenser will probably lie between the jet, surface, and ejector types, the final decision depending on amount of space available and the inclinations of the engineer.

The ejector condenser requires the largest quantity of water for a given quantity of steam, so we will first assume that this type will be used, and then modify conditions somewhat for other types. For satisfactory working the ejector type should be fed with water under a head of about 15ft., giving in the present case a required lift of 40ft. The most economical way to obtain this would be by using centrifugal pumps direct-coupled to electric motors. The centrifugal pump has its maximum efficiency when pumping to a height of about 20ft., the efficiency then being about 70 per cent., gradually falling as the head is increased; at a head of 40ft. the efficiency would be somewhere between 54 and 60 per cent. The flow through pump for a lift of H feet should be $\cdot 25 \sqrt{2\,g\,H}$; $g = 32{\cdot}2$, or about 4ft. per second in case under consideration. The velocity of delivery and suction should not exceed 6ft. per second. The mouth of the delivery pipe to tank should be submerged so as to keep the pump flooded.

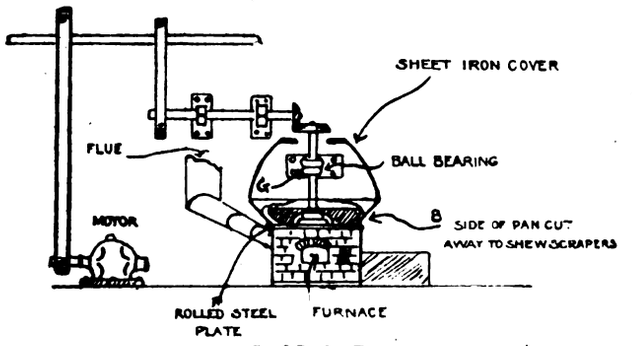
If the jet or surface types are used, a smaller quantity of water is required, and the water could, especially with the latter type, be circulated straight through the condenser without using a storage tank, thus obtaining a greater efficiency of the pump due to decreased head. But this method cannot be recommended, as it is much more preferable to have a reservoir, which could go on feeding condensers in case of breakdown of pumps or pipes while the latter were being temporarily repaired, which would be a distinct advantage if the breakdown occurred in time of heavy load, as the engines could still be run condensing. And, again, at very light loads the tank could feed the condenser without continuously running the pump. We see that with the two latter types less water per pound of steam is required than with the ejector type. This would allow the use of smaller pumps and motors and diminished first cost, but against this must be set off the necessity of air-pumps, which are required with the jet and surface types, but not with the ejector type, a decided advantage in favour of the latter. It is quite common practice now to use centrifugal circulating pumps and steam-driven air-pumps. The use of steam or electrically-driven reciprocating pumps for circulating water is quite practicable, but cannot compare with the former arrangement either for economy or simplicity (owing to the entire absence of valves and their consequent troubles, in the centrifugal type). For particulars of pipes see answers to Question 596 in the issue of *Electrical Engineer* for July 24, 1903. A U-bend in a pipe causes a distinct loss of head, but not so great a loss as an ⌒ bend, as the loss at the second bend is less than that at the first. The pipe should have

Digitized by Google

as few bends as possible, the bends having as large a radius as possible. Provision should be made at the mouth of suction pipe for keeping out pebbles and as much sand as possible; and the outlet from tank to condensers may with advantage be kept a few inches from bottom of tank, so that any sand or sediment which gets into tank may settle at bottom, and will not be led into condensers. Wash-outs and overflows should be provided for tanks. Automatic regulation of water-level can readily be supplied, and should depend on conditions and position of tanks, pumps, etc.—ERG.

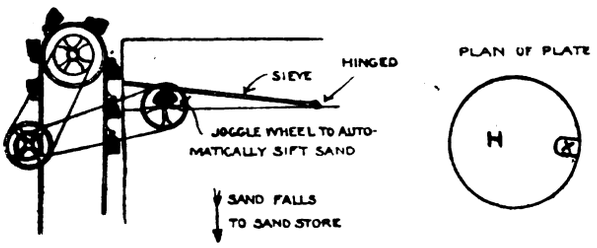
Question No. 602.—Describe a suitable form of sand-drying stove capable of delivering one ton of dry sand per day for use in car hoppers. The car-shed does not adjoin the power-house, so that flue gases are not available. Discuss the relative advantages of hand and mechanical feeding in such an apparatus.

Best Answer to No. 602 (*awarded* 10*s.*).—The best method of mechanically drying sand for use on tram tracks is illustrated below, with a description of the method of working. The part A is built up of firebrick, and on top is laid a rolled-steel plate about 1in. thick. The firebricks should be dipped in a thick solution of fireclay, so as to get close contact between bricks. The furnace brickwork is about 6ft. square. B is ordinary sheet iron forming the sides, it being kept in position by being riveted through small knee-pieces to the base-plate. There is a saddle bolted in the centre of the plate, forming a guide for the shaft, but it should be noticed that the shaft should not rest in this



Sand-Drying Pan.

saddle, as the heat would cause it to seize. The bearing at the top marked G is a cupped ball bearing, and the weight of the shaft should be taken at this point. In setting the bevel wheels, care should be taken to see that the teeth do not engage closely; about ½in. should be allowed for expansion when the fire is on. Sketch H shows plan of plate, X being a piece cut out with door fixed to slide underneath so as not to foul scrapers when revolving. This door is opened when a charge of sand is sufficiently dried, and the sand falls into a hopper, where it is picked up by a chain-bucket conveyor, and is dropped



at the top into a sieve, which is constantly kept in motion by a joggle wheel worked from the same shaft. This sifts all the stones from the sand, so that there is no danger of the outlet of the sand-boxes on the cars being stopped up, which might lead to serious consequences should the braking action on the car fail on a greasy rail. The sand is then ready for use. The furnace should be started with coal and kept up with damp coke.

There is no question as to this mechanical method of sand drying being far superior to the manual method, as from experience it is proved that in the latter case it takes about four or five men to do the work of the one man necessary to attend to the apparatus in the former method, besides which it is about 200 per cent. more economical from a fuel consumption point of view.—O. H M.

SHIPLEY ELECTRICITY WORKS.

Mr. S. D. Schofield, resident electrical engineer to the Shipley Urban District Council, has forwarded us a copy of the balance-sheet, analyses of costs, summary of expenditure, and return of units sold in connection with the Council's electrical undertaking for the year ending March 31 last, and also comparative costs for the part of year ending March 31, 1902. Supply was first given for lighting and power on July 26, 1901, there being three consumers connected up, with a total connection equivalent to 100 8-c.p. lamps; the total connections at the end of March, 1903, were equivalent to 8,147 8-c.p. lamps. This includes an equivalent of 4,237 8-c.p. lamps for 26 motors on hire in the town, the total brake horse-power being 169½. Traction supply was commenced on May 5, 1902, and the load factor has been calculated out from that date on, the running hours per day. These works are combined with the destructor and sewage works, and no charge is made by the Sanitary Committee for steam generated by the destructor boiler. On the other hand, the Electricity Committee bear the cost of management and superintendence of the destructor, sewage pumping, and sewage treatment, providing the current for the sewage pumps, clinker breaking and screening machinery, works lighting, and various small motors at the works, free of charge. The units used on works, including the above, last year were 92,542, and are not included with the units sold. Appended we give an abstract of the accounts. The amount of capital expenditure on March 31 last was £30,738. 5s. 1d.

PERSONAL.

Mr. F. W. Hewitt, the chief assistant of the electrical engineer, has gained a first prize offered by the Municipal Electrical Association for a paper on "Fuses."

The first annual outing of the Dartmouth staff of the Urban Electric Supply Company, Limited, took place on Saturday, Aug. 1. The party proceeded by train to Paignton, drove to Haytor Rocks *via* Totnes and Asberton. Dinner was served at the Rock Hotel, Haytor.

Digitized by Google

Leaving Haytor and proceeding over the moors, the next stop was made at Beeky Falls, and Bovey Tracey (where tea was provided) was reached at 5.30. Leaving at 7.30, the 9.10 train for Dartmouth was met at Torre, ending a most successful and enjoyable day.

We understand that the tramways department, with that of the Electricity Committee, is to be under one manager, and that the salary of Mr. C. J. Spencer, the tramways manager, is to be increased from £500 to £700 per annum, with annual increases of £100 up to a maximum of £1,000.

The Hoylake and West Kirby Urban District Council have appointed Mr, Chas. J. Turner, one of the mains assistants from the electricity department of the metropolitan borough of Islington, chief assistant to Mr. H. G. M'Haffie, the resident electrical engineer.

Messrs. Gent and Co., Faraday Works, Leicester, have appointed Mr. Harold Elliot, of 30, Bootle-street, Manchester, to represent them in Lancashire, Cheshire, North Wales, and West Riding of Yorkshire.

Mr. J. C. Vaudrey, M.I.C.E., M.I.E.E., who is retiring from the position of city electrical engineer at Birmingham, has been presented with a silver salver from the staff and employés of the electric supply department as a token of their esteem. Unfortunately the state of Mr. Vaudrey's health rendered a public presentation impossible. The salver was presented privately by the works manager.

The Hull Council have appointed Mr. Joseph Wilkinson to the post of tramway electrical engineer at a salary of £300 a year, and they appointed Mr. Herbert Bell to be the city electrical engineer, and devote himself exclusively to the electric lighting undertaking at a salary of £400 a year.

Mr. R. L. Horsfield, the chief clerk at the Bradford city tramways office, takes up his new duties as manager of the Walsall tramways on Sept. 1 at a salary of £200 per annum, rising £25 a year for meritorious service to £250 a year. Altogether there were close on 60 applicants.

We understand Mr. Frederick Groves, the tramways manager at Reading under the horse system (whose present appointment ceases on Oct. 31 next), is to be continued in the service of the Corporation as traffic superintendent under Mr. Binns, the engineer and manager, at a salary of £200 per annum.

Mr. Frank Ayton, who has been engaged since October last as resident engineer at Ipswich, representing Messrs. Kennedy and Jenkin, has been appointed engineer and manager of the electric light and power station and tramways undertaking, at a salary of £400 per annum, with an understanding that his salary would be increased by £40 per annum for three years.

LEGAL INTELLIGENCE.

ELECTRICITY METERS.

In the House of Lords judgment has been given in the appeal of the plaintiffs in the action Chamberlain and Hookham, Limited *v.* the Corporation of Bradford. The action was brought by the appellants to obtain an injunction to restrain the Corporation from infringing letters patent in respect of an invention of improvements in electricity meters, parts of which improvements are applicable to dynamo-electric generators and motors, and for damages on account of profits. The respondents denied the infringement, and said the letters patent were invalid. Mr. Justice Farwell found in favour of the respondents, and the Court of Appeal affirmed his decision. The House of Lords now dismissed the appeal, with costs.

HIRAM MAXIM ELECTRICAL CORPORATION.

In the Chancery Division on Thursday, Mr. Justice Farwell heard the case of Pulsford *v.* Devenish. The plaintiffs, Emile Pulsford and the Société Centrale d'Electricité et de Lampes, claimed damages against Mr. M. Devenish, of 44, Gillingham-street, London, the liquidator of the Hiram S. Maxim Electrical Corporation, Limited, for wrongfully distributing the assets without providing for the claims of the plaintiffs. The hearing was adjourned.

THE USE OF HIGHWAYS.

In the Chancery Division of the High Court on Tuesday (before Mr. Justice Swinfen Eady), Mr. Eve, K.C., applied on behalf of Mr. Morgan, of 72, Chepstow-road, Newport, a hay and corn dealer, for an injunction against the Corporation of Newport restraining them from unlawfully interfering with the plaintiff's user of the highway in front of his premises by the tramways of the defendants. There was a cross motion to restrain the plaintiff from interfering or obstructing the passage of the trams through the streets of Newport. The Corporation tramways ran in front of the plaintiff's shop and premises. At the part of the road where plaintiff's house stood the roadway was only 29ft. Notwithstanding this fact, the Corporation had proceeded to lay a double line of tramway at that spot, though the plaintiff's advisers had pointed out to the Town Council that it would be better to have what were called interlacing lines. The result was that when the trams came along they found the plaintiff's carts standing in front of his premises, loading or unloading, and there was not room for the tram to pass. The drivers stood and clanged their bells, and occasionally used opprobrious epithets to plaintiff's customers, whose carts were blocking the road. Sometimes they went so far that the Corporation officials took the names and addresses of plaintiff's customers, and even threatened prosecution, in one case the aid of the police being sought. There was no case where the obstruction of the tram had lasted more than five minutes, and yet the Corporation had gone to a Mr. Frost, who supplied plaintiff with goods, and warned him, with the result that he had declined to supply more goods.

Mr. Eve said the evidence was that frequently two or three trams passed together, owing to blocks at other places. Sometimes the tram men removed the carts, and then there was trouble. The plaintiff had as much right to use the road as the Corporation if he did not unduly occupy it. Owing to these difficulties the plaintiff's business in the last few months had gone down some 50 per cent.

The **Judge** said no doubt the Corporation wished to use the trams, and it was very irritating to them to be obstructed; but on the other hand he could quite see that plaintiff wished to make reasonable use of the highway. A man was entitled to earn his living by unloading or loading his goods at the shop door; but it must be done reasonably and without obstructing others. He thought it was unreasonable when there was a cart at plaintiff's door for the tram drivers to sound their gongs unreasonably. He did not think that Mr. Micklem had satisfied the Court that there had been unreasonable obstruction on plaintiff's part.

After further discussion, it was arranged that the Corporation should reduce the pathway to 4ft., so as to throw enough space into the roadway as to enable the plaintiff's carts to stand in front of his house, and at the same time to allow the trams to pass. On the Corporation undertaking to do that there would be no order made on the motion.

RIGHTS OF TELEPHONE COMPANIES.

Mr. Justice Buckley on Wednesday had before him the case of the National Telephone Company, Limited *v.* the Corporation of Hull, upon a motion to vary the minutes of the order as drawn by the registrar.

Mr. J. M. Astbury, K.C., for the plaintiffs, said that the motion was with regard to the question of costs of the action, and the simple question was whether the plaintiff had to pay the costs as between solicitor and client. The action involved the short point of whether the company was, under the latest Telephone Act, entitled to a renewal of their license from the Postmaster-General, or whether a notice given by the Corporation determining an agreement of 1899, by which the company maintained a telephone system in Hull, deprived them of that right. By the agreement of 1899 the Telephone Company had power to lay underground works in Hull. There was a provision in the agreement that by a certain notice given by the Corporation, they could determine the agreement. The Corporation gave that notice, and when the new Act of Parliament came into force the question arose of whether the Hull Corporation would have their own system and deprive the Telephone Company of the expenditure they had incurred in laying down and maintaining their system. The court had held against the plaintiffs, and they were ordered to pay the costs. He contended that as the defendants had given notice under the terms of the agreement, and not under any Act or in the exercise of any public authority, the question turned upon the agreement between the parties. The question had nothing to do with the Public Authorities' Protection Act, and therefore the defendants were only entitled to party-and-party costs.

Mr. Otto Danckwerts (for the Corporation) submitted that the question turned upon the statute, and in defending the action the Corporation were defending a public right, and were, therefore, entitled to the protection of the Act.

His Lordship said that, in his opinion, the Public Authorities' Protection Act did not apply. There was no duty on the part of the Corporation to determine the contracts with the plaintiffs, nor were they in so determining it acting as a public authority. They thought it right to determine it under a clause of revocation which they had reserved to themselves, and under the circumstances they were not entitled to the benefit of the Act. He, therefore, struck out of the minutes of the order the words "as between solicitor and client," and ordered the defendants to pay the costs of the motion.

DAMAGES FOR COLLISION.

At the Nottingham County Court last week £28. 18s. were obtained from the driver of a conveyance as damages for personal injuries. It appeared that on August Bank Holiday of last year a collision occurred between a tramcar in which plaintiff was riding and a dray, the shafts of which penetrated one of the windows. Plaintiff was injured by the broken glass and her child also, and she fainted. She was removed to her home and was under medical treatment for some time, and her health had suffered. The driver of the car stated that he was travelling at the rate of four miles an hour. After the accident he asked the defendant's man why he did not look where he was going, and he replied that he did not know about the cars. He admitted that he heard the bell, but said that he wanted to get to market. Defendant saw the driver and asked him to say that it was a pure accident, but he declined.

INTERFERING WITH THE TROLLEY POLES.

At the Spelthorne Petty Sessions, held at Sunbury on Wednesday, George Lush, 25, a carpenter, of Parkside, Windmill-road, Hamptonhill, was summoned for wilfully endangering the safety of passengers on an electric car of the London United Tramways Company by removing the trolley pole by means of which the electric current is communicated to the car. Defendant went into the box and swore that he never pulled down the trolley pole. He said he helped to put it back. The magistrates imposed a fine of £3 and 15s. costs, or a month's imprisonment.

COMPANIES' MEETINGS AND REPORTS.

LIVERPOOL OVERHEAD RAILWAY.

The half-yearly meeting of the Liverpool Overhead Railway Company was held on Tuesday, Sir Wm. B. Forwood, chairman of directors, presiding.

The **Chairman** said the report abundantly justified their recent expenditure of capital upon accelerating the service. The passengers carried during the half-year ended June 30 last numbered 5,514,000, an increase in round figures of half a million. Moreover, it was only 100,000 fewer than the record half-year. He pointed out that they were now putting aside for renewals and for the tramway sinking fund, to which they had contributed £500, a sum of £4,000 a year. The fund, he was glad to say, now amounted £26,200, which he considered was a very handsome sum. They proposed, with the shareholders' approval, to pay dividends at the rate of 5 per cent. per annum on the preferred shares, which would amount to £3 000, and 1¼ per cent. upon the ordinary shares, amounting to £3,125. This would leave a balance of £3,747. 5s. 10d. to be carried forward. During the half-year two Bills had passed through Parliament and received the Royal assent, in which they would be considerably interested. The first was the Bill of the Cheshire Lines Company to make a line connecting St. Michael's Station on the Cheshire Lines with the Overhead Railway at the Herculaneum Dock, thus forming a link with the Cheshire Lines, and enabling them to run their trains from their suburban stations, and also from Manchester and Warrington, along the Overhead Railway. The other was the Bill of the Seaforth and Sefton Junction Railway, and it was proposed to join the line running from the Central Station, Liverpool, to Southport at Aintree, and to form a junction with the Overhead Railway at Seaforth Sands, thus effecting a connection between the Overhead Railway and Southport, and forming a very important link or circle round the outside of Liverpool. They had arranged to work the trains that might run upon that line electrically off the Overhead system upon terms which had yet to be negotiated. The agreement with the Lancashire and Yorkshire Railway, which he mentioned at the last meeting, was expected to be concluded within the next few weeks. By that agreement they would connect with the Lancashire and Yorkshire Railway at their Seaforth Station. The system to Southport was at present being electrified, and he could not but think that when these arrangements were completed with their new line of railway very great advantage must result to the Liverpool Overhead Railway Company. Their structure and equipment had always been well maintained, and he believed it was in as good a condition to-day as on the day it was laid down. The service had been continued with great regularity. He was sorry to say they had not yet been able to institute a regular five minutes' service, as they were still short of some of the equipment necessary to do that, but he hoped in the course of a few weeks they would have a five minutes' service throughout the day. While they gave their shareholders this half-year £3,125, they had practically to pay the same amount in rates. This railway was really constructed more for the good of the trade of the port than for the shareholders - because they were all more or less philanthropists in the matter—and he did think they were unduly taxed when they had to pay to the local authority a sum exceeding £6,000 a year for rates and taxes.

The report (which appeared in our last issue) was adopted.

On the proposition of the **Chairman**, seconded by **Sir Edward Lawrence**, dividends were declared at the rate of 5 per cent. per annum on the preference shares and 1¼ per cent. per annum on the ordinary shares.

A vote of thanks to the chairman for presiding terminated the meeting.

LEYLAND AND BIRMINGHAM RUBBER.

The ordinary general meeting of the shareholders was held last week at Leyland, near Preston.

Mr. Jas. E. Baxter, who presided, congratulated the shareholders on the property. They had started in 1899 under the new form of the Leyland and Birmingham Company. They paid 6¼ per cent. in the first two years, 7½ in 1901 and 1902, and 8¾ in 1903. Since the end of the year which ended on June 30 the sales had very materially increased. They had increased up to July 18 to £3,345, or more than £1,000 per week. They had opened new markets with very considerable success. The tyre trade was bound to improve. The motorcar had come to stay, and was bound to be a very large and profitable business. The directors were looking upon that side of the question with great hopes, but they were not dependent in any case on specialities for realising this profit. They were building large new offices and warehouses necessary for the extension of the business, and it would also be necessary, before the year was out, to spend money in providing electrical power, engines, boilers, and further buildings.

The report was adopted, and the dividend was agreed to. Mr. S. Whitehead, the retiring director, was re-elected, and a special vote of thanks was accorded to Mr. Shutt, the secretary, and the managers.

WIDNES AND RUNCORN ELECTRICAL BRIDGE.

The sixth ordinary general meeting of the shareholders of the Widnes and Runcorn Bridge Company was held on Tuesday.

The **Deputy-Chairman** (Sir Henry Seton-Karr, M.P.), who presided, said the towers on each side had been erected to a height of about 160ft., the total being 190ft. The masonry was almost complete, and the wires for the cables were undergoing satisfactory tests. The final contract, that for the electrical installation and equipment, had been let to Messrs. Mather and Platt, of Manchester, who undertook to have the work completed within six months. The engines, dynamos, etc., were being made in duplicate, so that in the event of a breakdown the traffic would not be suspended. This contract included the machinery for driving the transporter car and for the lighting of the bridge. Having drawn attention to a pamphlet, prepared by the engineers, setting forth the history and features of the scheme in detail, Sir Henry said he hoped the bridge would be completed before the next half-yearly meeting.

The report was adopted, and the suggestion that the Prince of Wales, or, failing H.R.H., then some other member of the Royal family or other important personage, should be invited to ceremonially declare the bridge open was received with enthusiasm. The whole of the capital of the Company (£100,000) has been subscribed, £70,000 being called up. Only £500 of the calls are in arrear. The amount expended to date of report was £56,004, there being £13,700 balance in the bank. The bridge has a clear span over the Mersey of 1,000ft. The parliamentary powers to construct was obtained, after considerable opposition, in 1900.

METROPOLITAN DISTRICT RAILWAY.

Mr. R. W. Perks, M.P., at the half-yearly meeting on Thursday, said the work of electrification upon the railway was proceeding very rapidly. There were at present 1,000 men employed on this important work. Six hundred men were engaged constantly in laying the conductor railways carrying the ducts under the platforms, and doing general constructive work, which had already been completed on the Ealing and Harrow line. The Ealing and Harrow Railway was working under difficulties, but the effect of their running had already been to throw open for building purposes various estates both on the Harrow and the Hounslow line. At Whitechapel and Bow they had done an enormous business in the morning and evening, but, unfortunately, they could not get a sufficient number of trains through at present on the Tilbury Railway to show an adequate return upon the Whitechapel and Bow line. He did not see any reason why, if the Board of Trade sanctioned their automatic signalling apparatus, they should not run 40 to 50 trains per hour. Their electrical engineers proposed to run a five minutes' service of trains from Wimbledon, Richmond, Hounslow, Ealing, and from Harrow—five services of five minutes' interval. The Metropolitan Company were urging them to increase the number of trains running upon the Inner Circle. At the present time they ran six in the hour. It was possible that by arrangement they might increase that service to 10 in the hour. It was a matter they would have to consider with the Metropolitan Company. The rolling-stock which was now being ordered for the whole of the District Railway would provide a carrying capacity of from 100,000,000 to 120,000,000 passengers per annum. It might be necessary to ask Parliament to sanction a uniform fare of 2d. all over their railway without reference to class. That was the principle accepted by nearly every civilised country but our own. They carried at the present time from 45,000,000 to 50,000,000 people a year, and their passengers should bear in mind that the 10,000,000 or 11,000,000 of the working classes whom they carried at an abnormally low rate were practically being carried at the expense of the other travellers. It might be necessary to ask Parliament to sanction a uniform rate for rich and poor alike, regardless of place of booking and destination, and the time at which they might book. That was a democratic sort of proposition, which he thought ought to commend itself to Parliament and to the municipal governors of London, who seemed to think that they had a right to express an opinion as to the terms upon which London railways carried their passengers. As large ratepayers they were entitled to protest against the extravagant and wasteful expenditure of the County Council upon their abortive propositions which were from time to time, with strange insistence, brought before Parliament and almost invariably rejected. The report was adopted, and an extraordinary general meeting of the Company was subsequently held, at which resolutions were passed for the raising of additional capital.

NORTH METROPOLITAN TRAMWAYS.

The half-yearly general meeting of this Company was held at the Cannon-street Hotel on Wednesday under the presidency of Mr. George Richardson.

The **Chairman** said their receipts had fallen £34,613, the chief reason which accounted for these decreases being that the traffic on the Middlesex lines, which were sold to the Metropolitan Electric Tramways Company, was included in the corresponding period, and on this account there could be no fair comparison with the half-year ended June, 1902. The London County Council had not yet finally decided what system of electric traction was to be adopted on the tramways which they at present leased from them, but unfortunately their inclination seemed to be in favour of the more costly conduit system. This would mean about three times the cost of the overhead system. With regard to the West Ham scheme, it was in 1899 the Corporation of West Ham served notices upon the Company requiring them to sell the lines authorised by the Acts of 1869 and 1870. The Company lodged objection, and after lengthy negotiations an agreement was entered into with the West Ham Corporation, by which the Corporation agreed to buy the whole of the lines within their district, and also the two depôts situated at Stratford. The purchase money of the lines was fixed by agreement at £5,000 per mile of single line for the lines authorised by the Act of 1870, and at £5,500 per mile of single line for the remaining line. The value of the depôts was to be referred to arbitration in the event of the Company being unable to agree with the Corporation. The sale of lines was carried into effect as from June 30 last, and since that date the Company had by arrangement with the Corporation continued to work the line on behalf of the Corporation as part of the through system from Aldgate to Stratford.

The report was adopted, and it was further agreed that out of the £11,499 standing at the credit of net revenue account a dividend be

Digitized by Google

declared at the rate of 2½ per cent. per annum on the fully paid-up shares, and that the directors be authorised to enter into an agreement for the sale to the Metropolitan Electric Tramways, Limited (subject to the consent of the Board of Trade), of certain portions of tramway belonging to the Company, and situated in Stoke Newington and Hackney.

GREAT NORTHERN RAILWAY.

At the meeting on Tuesday **Lord Allerton,** who presided, said to some extent the decision as between steam and electric power would depend on whether a steam locomotive could be designed and constructed which would give much greater acceleration, coupled with more tractive power, without unduly increasing and concentrating the weight. At present—and it was the crux of the whole question—electric power appeared to have a decided advantage as regarded acceleration; but he had no doubt that the locomotive builders of the country realised how important this point was in connection with the future of their industry. The directors did not feel in a position at present to make any announcement on merits as between steam and electric traction, but meantime they were taking in hand improvements and enlargements which were common advantages under either or both systems. He hoped that they would be able to find some solution of a most difficult problem. The receipts on capital account in the half-year had amounted to £220,877, the whole amount practically being for the purposes of the Great Northern and City and the Great Northern, Piccadilly, and Brompton Railways. The opening for traffic of the Great Northern and City and the Great Northern, Piccadilly, and Brompton Railways was, it was hoped, approaching. Some persons, apparently, were sanguine enough to think that one of the lines would be open this year.

WATERLOO AND CITY RAILWAY.

Lieut.-Colonel the Hon. H. W. Campbell, deputy-chairman of this Company, presiding at the nineteenth half-yearly general meeting last week, said the traffic during the past half-year was greater than in the corresponding six months of 1902, although less than in the intermediate half-year ended last December. They carried 41,739 more passengers than in the half-year to June, 1902, and there was an increase of 47 in the number of season-ticket holders. A dividend at the rate of 3¼ per cent. per annum was proposed, which absorbed £8,775, and left £170 to be carried forward. At present the working Company ran as many trains as they could. If the storage accommodation for trains was enlarged they might be able to run more, and they would perhaps see this carried out in the near future.

The report was adopted.

LANCASHIRE ELECTRIC POWER.

Mr. F. E. Gripper, chairman of the Lancashire Electric Power Company, at the ordinary meeting of shareholders held on the 8th inst., said the Company having now raised the necessary capital for the equipment of their first station, which would be situate near Radcliffe, a contract has been entered into with the Lancashire Power Construction Company, Limited, to carry out the whole of the work for a plant with a total generating capacity of 6,000 kw., with substations and 60 miles of mains and cables, and as the local authorities with whom they had been negotiating were anxious for a supply of electricity in bulk, every effort was being made to expedite the work of construction, and by the end of 1904 or early in 1905 they expected to be in a position to afford such supply.

TAFF VALE RAILWAY.

At the half-yearly meeting at Bristol on the 11th inst., the **Chairman** mentioned that parliamentary powers had been obtained for the electrification of their railway, although the dreadful accident on a Paris railway would not encourage railways to proceed in that direction. They had intended to introduce on their line carriages with self-contained electric power, and with that object they obtained tenders from several electrical contractors. None of these tenders was, however, accepted, as from an inspection of the steam motor carriages now being used by the London and South-Western Railway it was concluded that it was better to adopt that mode of coach rather than a coach moved by electric power. They were now building, and it was nearly completed in their own sheds, a self-contained motor carriage as an experiment.

BELFAST STREET TRAMWAYS.

The report for the half-year ended June 30 last shows a credit balance of revenue account (after setting aside £1,400 to the credit of the sinking fund account) of £8,651, and from this the directors recommend a dividend upon the ordinary shares at the rate of 5½ per cent. per annum. This will leave £1,336 to be carried forward. Since the close of the half-year the Company has completed the purchase of the Sydenham District tramways and the Ligoniel tramways in accordance with the authority conferred upon the directors at the meeting held in February last. The Corporation will promote a Bill next session for the purchase of the Company's undertaking. This action of the Corporation, says the report, is a breach of the contract scheduled to and confirmed by the Act of 1893, whereby the date for the Corporation giving notice to purchase is postponed to 1907. In pursuance of this policy the Corporation has submitted to the Company a draft agreement for purchase. The directors regard this agreement as unfair, and in some respects even confiscatory in its terms, and they have informed the Corporation that, while the Company is now, as they have always been, willing on fair and reasonable terms to come to a voluntary agreement with the Corporation, so that electric traction may be established either by the Corporation or by the Company, they will resist to the utmost any attempt to force them into an agreement such as that of which the draft has been submitted.

BAKER STREET AND WATERLOO RAILWAY.

The report for the half-year ended June 30 last gives the capital expenditure for the half-year as £143,513; the estimated expenditure for the current half-year is £250,000. Satisfactory progress has been made with the construction of the works. The Company's Bills have now passed both Houses of Parliament, and await the Royal assent.

DUBLIN AND LUCAN ELECTRIC RAILWAY.

The report for the half-year ended June 30 last shows an increase of £61 in the total receipts. The expenditure shows a net increase of £167, including £137 for rebuilding a boundary wall, and £50 for repairs due to the great storm of Feb. 26. After providing for debenture interest there is a balance available of £837, out of which it is proposed that a dividend at the rate of 5 per cent. per annum be paid on the preference shares, that £300 be placed to reserve account, leaving £62 to be carried forward.

ELECTRIC WELDING.

A meeting of the Electric Welding Company, Limited, was held on Friday at the offices, 28, Basinghall-street, E.C. The Press was not admitted.

NEW COMPANIES REGISTERED.

Alexandra Simplex Motor Company, Limited.—Capital, £1,000. Objects: to manufacture, buy, sell, let on hire, and otherwise deal in motorcars and vehicles of every description and their component parts, fittings, and accessories; to adopt an agreement with C. Heyermans and A. Bluhm; and to carry on the business of automobile store and garage keepers, suppliers of electricity and motive power, electrical engineers, electricians, etc.

South-Western Electrical Company, Limited (78,230).—Capital, £5,000. Object: to carry on the business of electrical engineers, contractors, merchants, etc.

A. H. Miles, Limited (78201).—Capital, £1,000. Objects: to carry on the business of cycle and motorcar manufacturers, gun and ammunition makers, suppliers of electric light installations, manufacturers of phonographs, electric wiring, and bell fittings, etc.

Fabry Automobile Company, Limited (78,265).—Capital, £5,000. Objects: to adopt an agreement with M. Fabry, to cause to be manufactured, buy, sell, let on hire, and generally deal in motors and motor carriages and their parts, fittings, and accessories, to carry on the business of automobile store and garage keepers, motorcar repairers and cleaners, suppliers of electricity and motive power, electrical engineers, manufacturers of electrical apparatus, etc.

COMPANY LIENS REGISTERED.

Auckland Electric Tramways Company, Limited, London, W.C.—Trust deed registered July 31, for £200,000 debenture stock. Trustee: Electric and General Investment Company, Limited. Specifically charged on the concession, lands, and buildings, and generally, on the entire property, undertakings, and assets.

Ferranti Limited, Hollinwood.—Lien registered on Aug. 1 for £30,000 5 per cent. debenture. Holder: Parr's Bank, Limited. Charged on the undertaking and all the assets and property, including the uncalled capital, but subject to a first mortgage debenture for £10,000.

Wilson's (St. James's-square, Manchester), Limited (Ironmongers and Electricians).—Issue on July 28 of £4,250 debentures, part of a series created on July 23, 1903, to secure £4,500, charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. No previous issue of same series.

Bright's Light and Power, Limited.—A debenture for £2,000, created July 31, 1903, charged on the company's concessions, freehold and leasehold property, works, and plant in England or elsewhere, and (as a floating security) all its other assets, including uncalled capital, has been registered. Holder: C. Owles, 16-17, Russell-street, W.C.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Aranjuez.—The Municipality invite tenders for public and private lighting of the town. Tenders by Aug. 20.

Hackney.—The Borough Council invite tenders for arc lamps and pillars and distributing mains. Tenders by 31st inst.

Lisbon.—The Public Works Department require tenders for the public electric lighting of Macao. Tenders by Oct. 21.

Edinburgh.—The Corporation invite tenders for the supply of arc lamps for public lighting by Aug. 26. See advertisement.

Canea.—The Mayor of Canea invites tenders for the lighting by electricity of part or the whole of the town of Canea. Tenders by Aug. 28.

Beszterczebanya (Neusohl, Austria).—Tenders are required by the municipality for installation, buildings, etc., of a central station of a minimum capacity of 600 h.p. Tenders by Aug. 31.

Digitized by Google

West Ham.—The Borough Council invite tenders for traction switchboard, etc. Particulars from Borough Electrical Engineer, Abbey Mills, West Ham. Tenders by 4 p.m. on Aug. 21. See advertisement.

Avila.—The Department of the Interior, Madrid, require tenders for an electric light installation for public and private lighting. The latter will require about 6,000 lamps. Particulars from the above. Tenders by Aug. 22.

Madrid.—The Post and Telegraph Department require tenders for a telephone system in communication with the principal central station in San Lorenzo del Escorial and sub-central stations in Cercedilla. Tenders by Sept. 6.

West Ham.—The Town Council invite tenders for traction switchboard, etc. Further particulars may be obtained from Mr. James K. Bock, Abbey Mills, West Ham. Tenders may be sent to Mr. Fred E. Hilleary, Town Hall, West Ham, by 4 p.m. on 21st inst.

Madrid.—The Posts and Telegraph Department require tenders for installation and working of a telephone system in Gerona for twenty years, and also for installation of telephone between Gijon and Pola de Siero. Tenders by Aug. 25. Specification may seen at this office.

Shanghai.—The French Colony propose to instal motor-propelled tramways. Tenders may be sent by Oct. 31, 1903, to Secrétariat de la Municipalité Française de Shanghai. Particulars may be obtained from l'Office National du Commerce Extérieur, Rue Feydeau, 3, Paris.

Utrecht.—The Town Council will receive tenders for supply and erection of a central electric establishment for lighting, power supply, and working tramways. Contract, conditions, etc., to be obtained at the "Gemeente Secretaire" of Utrecht, on payment of 5fl. (8s. 4d.). Tenders by Oct. 1.

Swindon.—The Corporation invite tenders for the supply, delivery, and laying of all the rails, points, crossings, and accessories for the permanent way of the Corporation's tramways. Particulars from the engineers, Messrs. Lacey and Sillar, Manchester and Westminster. Tenders by Aug. 26. See advertisement.

Launceston (Tasmania).—The Mayor and Aldermen invite tenders for the supply of 500 or more electric meters. Particulars may be obtained on application to Mr. William Corin, city electrical engineer, Launceston, Tasmania, or to Messrs. John Terry and Co., 7, Great Winchester-street, London, E.C. Tenders by Sept. 28.

North Shields.—The Tynemouth Corporation invite tenders for the erection of an accumulator house at the electrical power station, North Shields. Plans and specifications may be seen at the office of Mr. John F. Smillie, borough surveyor, Tynemouth, to whom sealed tenders, endorsed "Tender for Accumulator House," are to be sent by 10 a.m. on 18th inst.

London, S.E.—The London County Council invite tenders for the supply, delivery, and erection in the electricity generating station to be established by the Council at Greenwich of four 5,000-h.p. vertical-horizontal steam-engines, each suitable for driving a three-phase generator. Particulars, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 6.

Portugal.—The "Diaro de Governo" of Aug. 5 contains a notice granting to the Conde de Vizella for 15 years the exclusive concession for automobile service on various roads in the districts of Loanda and Lunda, in Portuguese West Africa, with a preference, under equal conditions, of the establishment of other automobile services in the same districts upon conditions which are stated in the "Diario.""

Madrid.—The Posts and Telegraphs Department require tenders for the supply of 25 telegraph apparatus of the Hughes system and 25 motors with weight elevators for the same, for the service of the telegraph stations of the State, at the upset price of 2,530 pesetas, or about £73, for each apparatus with its accessories as detailed, and 408 pesetas, or about £12, for each motor with its corresponding elevator. Tenders by 22nd inst.

Batley.—The Corporation invite tenders for the mason, joiner, plumber, plasterer, slater, painter, heating engineer, and electric lighting engineer's work respectively, in erection and completion of additions to the present town hall. Plans and specifications, etc., can be seen, and bills of quantities obtained at the offices of Messrs. Walter Hanstock and Son, architects, Branch-road, Batley. Tenders to be sent to Mr. J. H. Craik, town clerk, by noon on Sept. 4.

Birmingham.—The Tramways Committee require the names of contractors who are desirous of tendering for the supply and delivery of materials and fittings as follows: (Section A) manganese steel points and crossings; (B) tapered steel side poles and bracket arms; (C) suspension ears, pull-offs, section insulators, and other overhead materials; (D) hard-drawn copper trolley wire and stranded steel span wire. Mr. John Price, city engineer, Council House, Birmingham.

Cardiff.—Tenders are required for new electrical department for lupus treatment, etc., at the Cardiff Infirmary. Plans, etc., may be seen at the office of the architect, Mr. Edwin Seward, F.R.I.B.A., from whom bills of quantities may be obtained on payment of cheque for £1. 1s., to be returned on receipt of a bona fide tender. Tenders, endorsed "Electrical and X-Ray Department," to be delivered to Mr. Leonard D. Rea, secretary and general superintendent, by 12 noon on 18th inst.

RESULTS OF TENDERS.

Colchester.—The Council have accepted the tender of Statter and Co. to supply a traction switchboard for £408.

Sleaford.—The Urban District Council have accepted the tender of Messrs. Parker and Co. for engine, at £754, and Messrs. Babcock and Wilcox's tender for a boiler, at £625.

Dewsbury.—The Joint Hospital Board have accepted a tender of Robb and Mitchell, Ossett, for electric mains, switchboards, etc., at the hospital in course of construction, at the cost of £634. 17s. 4d.

Derby.—The Electric Lighting Committee have, subject to the approval of the Council, accepted the tender of Messrs. Radford and Greaves, amounting to £1,328. 17s. 6d., for the erection of a battery house.

Baltinglass (Ireland).—The Guardians have accepted the tender of Mr. J. O'Gorman, Hacketstown, for supplying and erecting electric bells throughout the workhouse, amounting to about 12 in all, at £1. 7s. 6d. and £2. 2s. each.

Lifts.—Messrs. Wm. Aug's Gibson, Limited, Temple Bar House, 28, Fleet-street, E.C., have obtained the contract for four electric lifts and two hydraulic lifts in the new premises of Messrs. Robinson and Cleaver, Regent-street, W.

Bradford.—The Corporation have accepted the tender of G. H. Woods, Slacke, and Co., Corporation-street, Blackburn, for the works and materials necessary for the electric lighting at the Cartwright Memorial Hall, Lister Park, Bradford.

Admiralty.—Messrs. W. T. Henley's Telegraph Works Company, Limited, have obtained from the Admiralty a contract for the electric lighting of the Gibraltar Dockyard, the contract including supplying and laying of cables, conduits, arc lamps, joint-boxes, etc.

Penang.—The contractors for the arc lighting of Penang, Messrs. Crompton and Co., have accepted the tender of Messrs. Rowland Carr and Co., 6 and 8, Lime-street-square, London, E.C., for the supply of the whole of the arc-lamp pillars and brackets in connection with their contract.

Wednesbury.—The Corporation have received the following tenders for erection of a sub-station in connection with the electricity supply undertaking: Hammond Bros., Darlaston, £1,147; W. T. Lees, Darlaston, £1,140; G. Summerhill, Limited, Wednesbury, £1,135; F. J. Smith, Wednesbury, £948.

Kettering.—The Urban District Council have received the following tenders, ranging from £1,205. 12s. 3d. to £560. 17s. (Messrs. Lees and Harrison, Leeds), for providing and erecting the steel trusses and other work required for 2,000 yards super of roofing on the buildings for the electricity and destructor works.

Ealing.—The Town Council have accepted the following tenders in connection with the electricity works: Wiggins and Co., Castlehill Wharf, Ealing, stoneware pipes; W. Ashby and Sons, Cement Works, East Greenwich, cement; W. H. Willcox and Co., 23, Southwark-street, S.E., cylinder and other oils, waste, etc.

Kingston.—The Town Council have accepted the tender of Bennis and Co., Limited, for fitting one of their machine stokers, fitted with patent pneumatic gear and self-cleaning compressed-air furnaces, to the No. 2 Lancashire boiler, at £107. 10s., and the tender of the Wheeler Condenser and Engineering Company for supplying a horizontal combined air and circulating pump, inclusive of suction and delivery pipes and valves, at £130.

Newcastle.—Messrs. Falconar, Cross, and Co., 4, St. Nicholas-buildings, Newcastle-on-Tyne, report an order for the electrical work at the Newcastle-on-Tyne Royal Victoria Infirmary, which is now in course of erection. The contract includes the whole of the lighting and power distribution, and also electric bells, telephones, fire-alarms, fans, and motors. The work is being carried out to the specification of Messrs. Dolby and Williamson, of London.

Ipswich.—The Council have ordered from the British Westinghouse Electric and Manufacturing Company a combined motor watering and track-cleaning car complete at £864. 6s., and a telescopic car and breakdown wagon complete at £70. Eleven firms tendered for the supply of meters, and the tender of the Reason Manufacturing Company, at £273. 5s., has been accepted for the four smaller ones, and that of Ferranti Limited, at £96. 5s., for the larger ones.

Bracebridge Asylum.—The following tenders have been accepted in connection with the proposed plant for the supply of electric light and power to the asylum: Chloride Electric Storage Company, Limited, Clifton, supply and erection of a storage battery, £559; W. Foster and Co., Limited, Lincoln, supply and erection of two engines and dynamos, one motor-generator, main switchboard, meters, etc., £1,211; H. T. Hazzledine, Lincoln, supply and fixing of electric wires, switches, etc., £2,250.

Engines.—Messrs. W. H. Allen, Son, and Co., Limited, Queen's Engineering Works, Bedford, report the following recent orders: One 750-i.h.p. engine and surface-condensing plant for the Fairfield Shipbuilding Company; one 105-b.h.p. engine for Messrs. Mather and Platt; one 30-b.h.p. engine for Messrs. Parkers; one 30-b.h.p. engine for the Lahmeyer Electric Company for the Chelsea Polytechnic; nine 24-b.h.p. engines for the Union Castle Company; one 133-b.h.p. engine for the British Schuckert Company; three 900-i.h.p. triple-expansion engines and surface-condensing plants for the Cardiff Railway Company; two 10-b.h.p. engines for the Adelaide Steamship Company.

Aberdeen.—The Tramways Committee have received the following tenders for the electrical equipment of their Torry route of tramways, comprising the supply and laying of cables and erection of overhead gear: British Insulated and Helsby Cables Limited, Prescot, Lancs. (accepted); W. T. Glover and Co., Limited, Manchester; G. Hill and Co., Limited, Manchester; W. T. Henley's Telegraph Works Co., Limited, London; St. Helens Cable Company, Warrington; Callender's Cable and Construction Company, Limited, London; Anchor Cable Company, Limited, Leigh; Western Electric Company, London; Land-und-Sekabelwerke Aktiengesellschaft, Coln-Nippes, Germany.

Bootle.—The following tenders have been accepted: J. Riddock, Bootle, construction of foundations for extension of boiler-house, £1,033, and construction of foundations for engines at a schedule of prices; Yates and Thom, Blackburn, supply and fixing of four Lancashire boilers with superheaters £2,569, supply and fixing of one fuel economiser and fittings £425, and supply and fixing of

Digitized by Google

coal conveyor and overhead bunkers £954; Ferranti Limited, Hollinwood, supply and delivery of two steam dynamos, spare parts and switchboard, £8,711; Fawcett, Preston, and Co., Limited, Liverpool, supply and erection of an iron bridge over the Leeds and Liverpool Canal, to carry cables, subject to agreement with the canal company, £180.

Heston and Isleworth.—The following tenders have been received by the Urban District Council for electric lighting:

Section 2.—Engines and dynamos, boosters and balancers switchboard and connections, condensers, pumps and accessories, with cooling plant, water softener, travelling crane, tools, etc.

Bruce Peebles and Co.	£5,359

BUSINESS NOTES.

TRACTION.

Perth.—The Tramways Order Confirmation Bill has received the Royal assent.

Bristol.—The tramways carried nearly a quarter of a million passengers on Bank Holiday.

Fleetwood.—Record business has been done on the Fleetwood trams during the holidays.

Ipswich.—The Corporation have received a deputation against the running of trams on Sunday.

Glasgow Corporation Tramways Order.—This Bill has been read a third time in the House of Commons.

Mexico.—The Mexican Electric Vehicle Company has given up business, as there was not sufficient local demand for motors and garage.

Crewe.—The Corporation have adopted the agreement with the Crewe and Nantwich Tramways Company, as revised by Messrs. Hewitt and Rhodes.

Newcastle.—The Corporation tramways carried 764,660 passengers in the week ended Aug. 1; 76,152 miles were run for £3,485, giving 10·98d. per car mile.

Wednesbury.—Terms have been agreed to by which the electrification of the tramway connecting Wednesbury and West Bromwich will be commenced forthwith.

Oldham.—The Town Council have obtained sanction to borrow £62,000 for tramway plant and street widening, and £17,000 for electrical equipment of the lines.

Leicester.—The permanent way on the chief trunk line of the new tramways—that is to say, the London-road and the Belgrave-road—will be probably completed by the end of October.

Barrowford.—The first trial trip on the new length between Foulds-street and Higherford Bridge has been made. The journey only occupied about 10 minutes, and was performed without a hitch.

Aberdeen.—A sub-committee of the Corporation Tramway Committee have resolved to recommend that ½d. fares be introduced. The question will come before the Council next Monday for confirmation.

Italy.—The Mediterranean Railroad Company has presented to the Italian Government a plan for an electric line from Rome to Naples of 210 km. The cost of constructing this line would exceed £4,000,000.

Newport (Mon.).—The tramways receipts for the month of June were £1,956. 6s. 8½d., the number of passengers carried being 465,333, against £1,424. 14s. 8d. receipts from horse cars for the corresponding month of last year.

Yardley.—The Tramway Committee intend to commence the construction of the lines on the two main roads, while the work on the Coventry-road route, from Small Heath to the Swan Inn at Yardley, is to be proceeded with at once.

Hillingdon.—The London United Tramways, Limited, are applying to the Board of Trade for a 12 months' extension of time in which to complete their light railway to Uxbridge under an order of 1898. The Parish Council have asked the company to widen the roads.

Burton.—The question of the running of trams on Sundays in Burton has caused the Wesleyans of Burton to issue a notice, in which the ratepayers belonging to the church and congregation are earnestly entreated to record their votes against such a measure.

Dundee.—The returns for the city tramways for the week just ended show receipts amounting to £872. 17s. 4½d., representing 224,799 passengers—increases of £82. 10s. 6d. in receipts and 21,284 in passengers as compared with the corresponding week of last year.

Cardiff.—Application is to be made to the Board of Trade for a loan of £4,000 for the construction of a new tramway section in Meteor-street from Planet-street to the junction in Constellation-street. In the week ending Aug. 8, 682,261 passengers were carried.

Portsmouth.—On Bank Holiday the trams earned a record amount. During the day no less than £812 was taken, or an average of about £10 per car. The previous best day was Whit Monday, when £797 was taken. On August Bank Holiday a year ago the cars earned £600.

Birkenhead.—The trams showed a fairly substantial increase for the last Bank Holiday. An increased service was run all day. The following are the returns for the three days: 1903—passengers 120,294, receipts £586. 9s. 0½d.; 1902—passengers 116,688, receipts £592. 7s. 5½d.

Beddgelert Light Railway.—In a letter to the Glaslyn Council, read at the last monthly meeting, the secretary of the North Wales Narrow-Gauge Railway Company stated that the company intended to proceed with the proposed railway from Rhyd-ddu to Beddgelert as soon as possible.

Sheffield.—At the last meeting of the City Council it was proposed that a sum of £5,000 be contributed out of the surplus of the tramways undertaking towards the new university buildings, conditional on a grant of a charter being made and the amount being spread over a period of five years.

Colne and Trawden Light Railway.—An extension of time has been granted in which to construct railways No. 2 and No. 3 (part of) on the express understanding that railway No. 4 was completed by June 17, 1904, in accordance with the arrangement made at the enquiry before the Board of Trade.

Elland.—The Elland Council recently sent in an application to the Huddersfield Corporation that that body should extend their tramway service to Elland. We understand that a reply has been received by the Elland Council stating that at present the Corporation cannot see their way to effect the desired extension.

Dunfermline.—Now that the Fife Electric Power Bill has been passed, and only awaits the Royal assent, consideration has been turned to the proposal of forming a company in Dunfermline, with the object of making a tramway from Dunfermline to St. Margaret's Hope. Probably other districts will be opened up.

Reading.—Up to Tuesday night, Aug. 4, 347,319 passengers had been carried, and up to Wednesday night £1,655. 12s. 3d. has been taken in fares. On Bank Holiday the persons carried numbered 51,310, and the money taken amounted to £247. 0s. 10d. During the first 10 days only about 20 cars were in use.

Doncaster.—Major Druitt, inspector for the Board of Trade, on Tuesday inspected the new tramway lines at Doncaster, from Station-road to Beckett-road, Wheatley, and the loop line from Station-road by Printing Office-street to High-street. The Priory-place loop is 1 furlong 3½ chains in length, and the Beckett-road route 3 furlongs 4 chains.

Chile.—The Government have appointed a special commission for the consideration of the question of applying electric traction to that part of the State railways between Santiago and Talca, taking into account the hydraulic power that might be available, and also for the work of affording additional power for working the line between Lhai-Lhai and Las Chilcas.

Leeds and Wakefield Tramway.—At a recent meeting of the Stanley District Council it was announced that the tramway syndicate had decided to commence work on the construction of the Leeds and Wakefield tramway on Aug. 13. A start was to be made at the Stanley and Wakefield boundary (opposite the Vine Tree Inn, Newton), working towards Leeds.

Wandsworth.—The Council have informed the London County Council that they regret that it is not apparently intended to apply for powers in the ensuing session of Parliament for the extension of the tramways along East-hill and High-street, Wandsworth, and asking the London County Council to consider the desirability of including such powers in their Bill.

Prestwich.—The Urban District Council have decided to apply to the Board of Trade for sanction to the borrowing of £24,125 for the construction of the electric tramway line in Bury Old-road, and the costs incurred in the construction of the tramways. The new line will connect the Manchester and Salford lines. It will run from

Digitized by Google

Heaton Park main entrance to Besses-o'-th'-Barn, where it will join the Salford tramway line, which ends at Whitefield.

Wolverhampton.—A letter from the Tradesmen's Association, urging the Council to have the tramways constructed along the Dudley-road, Willenhall-road, and Wednesfield-road, to end the isolation of the town and the outside districts, has been referred to the Tramways Committee, asking them to proceed without delay in establishing communication with the outside districts. A special meeting of the Council is to be held next month to direct the work to be carried out.

Colchester.—Application is to be made for a further prolongation for three months of the time for the commencement of the tram works, "though in the sub-committee's view it may not be needful to take advantage of the extension." The Board of Trade sanction had been received to the borrowing of £61,164 for the purposes and periods undermentioned: permanent way, buildings, lands, etc., 30 years, £39,933; electrical equipment, with contingencies, 20 years, £10,831; cars, £10,400.

Coatbridge and Airdrie.—The Tramway Confirmation of Order Bill for these burghs has passed the third reading in the Commons, and may be expected to reach that stage shortly in the Lords. The tramways are to be driven by electricity generated at the works of the Scottish House-to-House Electricity Company, Limited, in Dundyvan, the company who are at present supplying the burghs with current for electric lighting. The contractors expect to start work on the 15th inst.

Hull.—About 300 of the drivers and conductors of the Hull Corporation tramways, through the kindness of Councillor Peter Atkinson and Mr. John Tapp and numerous friends, last week enjoyed a cruise on the River Humber. Breakfast and dinner were served aboard, and with music and dancing the time passed pleasantly. The party arrived at the pier about one o'clock, and before the men left the ship to take up their customary Sunday duty some speechmaking took place in the saloon cabin.

Poole and District Light Railway.—The petitions of all parties with reference to the Bournemouth Light Railway Bill have been withdrawn, and the Bill will now proceed as an unopposed measure. The agreement mentions that the Bournemouth Corporation should not accept a lease or enter into a contract with respect to the working of any tramlines in the county of Dorset (except the borough of Poole and the urban district of Branksome), unless they obtain the consent of the County Council of Dorset.

Blackpool.—Last week a cable was run from one of the Fleetwood Tramroad Company's feeders to one of the Corporation Promenade tramway poles at the Gynn Inn junction. The heavy Bank Holiday traffic on the Promenade and Lytham and St. Annes section of the Corporation line having strained the electrical energy at the municipal works, application was made for assistance from the Fleetwood Company's power station at Bispham. Mr. Cameron, the secretary and manager, at once complied with the request.

Manchester.—It appears that the refusal to carry passengers on the Manchester Corporation electric cars up the steep gradient from Chestergate into St. Peter's-square led to a threat to legally enforce the terms of the agreement between the Stockport and Manchester Corporation. The general manager of the Manchester tramways has recently placed an order for a number of cars to be equipped with the Westinghouse magnetic brake, by means of which he expects to be able to safely negotiate the heavy gradient and run through St. Peter's-square.

Douglas.—The purchase by the Town Council of the tramway system within the borough has turned out a great success. The first year's working was very satisfactory from a financial point of view, and ever since the receipts have been growing. Last week they exceeded those of the corresponding week of 1902 by over £200, while the increase in regard to the portion of the year up to the end of last week is nearly £1,000. It is expected that the result of the current year's working will enable a handsome contribution to be made in relief of the rates.

Halifax.—At the meeting of the Corporation last week it was agreed that the borough engineer be instructed to proceed with the extension of the tramways from Hove Edge to Brighouse (George Hotel), at an estimated cost of £10,378. 13s. 9d. (of this amount £2,103. 10s. having been already spent), on the terms set forth in the resolution of the Tramways Committee of July 23—namely, that the Brighouse Corporation excavate and pay the value of the granite, dross, and rolling where rails are laid in Upper Green-lane, Well Green-lane, and Laverack-lane.

Carlisle.—The Electricity Sub-Committee of the Corporation have had under consideration a letter from the tramway company with reference to a proposal by the company to run a 10 minutes' service of cars throughout the year, provided the Corporation would meet them by reducing the price charged for the current required for traction purposes. The sub-committee have passed a resolution recommending the Town Council to make a uniform charge of 1·6d. per unit on condition that the company guarantee a 10 minutes' service, and take a minimum of 350,000 units of electrical energy per annum.

Manchester.—The Tramways Committee are extending their lines in the direction of Middleton. At the present time workmen are constructing a new line in Middleton-road from White Smithy Bar to the city boundary. In continuation of this line the Salford Corporation will lay down rails from the city boundary up to the Three Arrows, where the lines will join the system of the British Electric Traction Company, which runs through the borough of Middleton. It has been suggested that a tramway line might be laid from the Middleton-road side of Heaton Park to a point in the park not far from the hall.

Yeadon.—At the last meeting of the Yeadon District Council the tramways question came up for discussion on an enquiry as to the exact position the Leeds and Guiseley scheme occupied. The clerk (Mr. H. Walmesley) was instructed to call a special meeting of the Council as soon as he had obtained any reliable information as to the position of affairs, the feeling on the part of the Yeadon councillors being that, if the present scheme collapsed, the construction of the tramways should be taken in hand by the joint Councils of Guiseley, Rawdon, and Yeadon, or the Leeds City Council be asked to carry out the scheme.

Brighton.—The following figures give the number of passengers carried on the Corporation trams for each of the first four days of last week, together with the receipts. Monday was Bank Holiday, and the other days those of the Brighton races. Out of the total number, 33,277 passengers paid the special 2d. fare during certain hours for the Race-hill trams. Monday proved a record for a day's passengers, and it is expected that the week will surpass any previous week's total: Monday, passengers 84,343, receipts £351; Tuesday, 56,144 and £283; Wednesday, 71,464 and £297; Thursday, 56,389 and £277—totals, 268,340 and £1,210.

Highgate Tramways.—The Middlesex County Council have in hand a scheme for the extension and construction of tramways at Highgate, N. For this purpose the Council have compulsorily acquired certain land and property in Archway-road, Highgate, amounting to nearly 3 000ft., and an enquiry was held at Westminster recently before Mr. Ralph Clutton, F.S.I., as sole arbitrator, to assess the compensation in a claim brought by the owners of the property. For the claimants £3,100 was asked for, but the Middlesex County Council, through their expert witnesses, put the value at about £600 to £800. The arbitrator reserved his award.

Rotherham.—The returns for the week ending Aug. 6 were as under: Tinsley, passengers 60,255, receipts £436; Kimberworth and Fitzwilliam-road, 54,428 and £201; Canklow and Rawmarsh-road, 39,869 and £129—totals, 154,552 and £769. These returns again greatly exceed all previous records. The figures for the preceding week were: passengers, 132 693; receipts, £600. The best day this week was Bank Holiday, when 39,871 passengers were carried and £207 in fares received. Since the opening of the first section on Jan. 31 the total number of passengers up to and including Thursday was 1,789,078, and the total receipts amounted to £6,450.

Perth.—At the last Council meeting a letter was read from the parliamentary agents intimating that the tramway provisional order had now passed the Commons, and awaited the formal Royal assent. The convener submitted the financial report by the tramway company directors for the month of June, 1903. The number of passengers carried during the month was 68,000, and the credit balance of assets over expenditure amounted to the satisfactory sum of £233 10s. 3d. The committee considered this extremely satisfactory, and they were strongly of opinion that the tramway directors should be asked to continue the management of the concern until the conversion to electric traction takes place.

Sunderland.—The Tramways Committee have determined to join the rails on the new Laurence-street route in the same manner as the rest of the system, with the addition of the scarphed or Dicker joints with anchor bolts, in preference to a new system of welding which was tested recently at Roker. At the last meeting a circular letter was read from the Board of Trade, in which it was recommended that in view of the fact that many people who had been knocked down by cars had been injured by the protruding step, folding steps should be adopted. Mr. H. England (manager) and Mr. J. F. C. Snell (electrical engineer) pointed out that such steps were impracticable and dangerous, and had not been successful in places where they had been tried. The committee agreed with the report of their officials.

Devonport.—The secretary to the Light Railway Commission has forwarded the following letter to the parties interested in the application of the Corporation to construct an electric tramway to Crownhill: "Sir,—With reference to the enquiry held by the Light Railway Commissioners at Devonport on Feb. 26 last, I am directed by them to inform you that they are satisfied that the preamble of the order to authorise the above-named light railway is proved, but that the submission by them of an order to the Board of Trade will depend upon the settlement of satisfactory clauses in particular as to road widenings, etc., if possible to be agreed between the Devonport Corporation and the Devon County Council, or in default of agreement settled by the Commissioners.—I am, Sir, your obedient servant, (Signed) ALAN D. ERSKINE."

Heywood.—The understanding which has been arrived at between Heywood and the Corporations of Bury and Rochdale for the Heywood tramways is, briefly, that the Corporations of the two adjoining boroughs should each run their cars to Heywood Market-place. They would purchase the tramways from the present company, Heywood would reconstruct the lines within the borough boundary, and then would lease them for 21 years to Bury and Rochdale at a rent equal to 10 per cent. on the capital outlay, Heywood to keep the line in repair. Latterly, however, the neighbouring Corporations have agreed that if they hold by this understanding they will lose by it, and an amended scheme has been submitted to the Heywood committee. The committee have decided that they could not accept the amendments; they could not see their way to depart from the original agreement.

Walsall.—At Tuesday's meeting of the Town Council the chairman of the Tramways Committee, Mr. Cope, said it had been stated that when the Corporation took over the tramways Walsall would be isolated from Wednesbury and Darlaston, as the British Electric Traction lines would break the connection. The committee knew there would be a difficulty, but it would have to be arranged mutually. He believed the borough surveyor and electrical engineer had had an interview with Mr. Lycett, but the committee had entered into no arrangement. The Town Clerk said the British Electric Traction Company could not construct a loop line to connect the existing Wednesbury

Digitized by Google

and Darlaston lines without the consent of the Council, who were quite masters of the situation. The Tramways Committee, however, did not wish to act dog-in-the-manger like, and he believed a spirit of conciliation would be manifested.

North Wales.—Messrs. Bruce Peebles and Co., Limited, of Tay Works, Bonnington, have secured the contract for the construction of the new electric railway being promoted by the North Wales Power and Traction Company, Limited. The scheme is for the harnessing of the immense watershed comprised in the lakes of Snowdon. The initial contract, amounting to £180,000, will supply approximately 10,000 h.p., and includes about 13 miles of electric railway, constructed on the Ganz high-tension system. The line will pass through some of the finest scenery in North Wales. It passes through the village of Croesor and amongst the numerous slate quarries in active operation in that district, and only awaiting railway communication with Portmadoc, where the slates can be shipped direct. At present, owing to the heavy cost of cartage, amounting to as much as 10s. per ton for a distance of 12 miles, several of the quarries have had to shut down.

Parliament.—After six months' sittings the Royal Commission on London Locomotion have adjourned for the summer recess, and will not meet again until the first week in October. While metropolitan tube schemes are thus stopped for the moment, work has been proceeding with those schemes which have passed the ordeal of Parliament. The line from Baker-street to Waterloo is being pushed on as rapidly as possible, and there is every probability that the new tube from Finsbury Park to Moorgate-street will be ready for the public about the end of the year. It does not appear that the restriction will apply to tramway extension schemes. During the session the London County Council have obtained legislative sanction to their proposed electric lines from Hammersmith to Harlesden in the west, and from Garratt-lane to the county boundary at Wimbledon in the south. Several other schemes have been adopted, and it is understood that these will be proceeded with.

Derby.—At the last meeting of the Council it was mentioned that the Brush Company had obtained the contract for the tramway cars through the contractors (Messrs. White). Some time ago three names were given by the contractors, and the committee were asked whether they would be satisfied with these firms—viz., the Brush Company, the Electric Contract Company, and G. F. Milnes and Co. The committee intimated that they would be satisfied with any of these, and the contractors then had the selection, and they nominated the Brush Company. The receipts of the Corporation tramways during the five weeks ended July 26 were £2,000. 19s. 11d., being an increase of £20. 13s. 8d. as compared with the corresponding period last year. The Board of Trade have approved the plans of the rail and substructure of the electric tramways, subject to certain minor conditions. The committee have visited Loughborough, Nottingham, and Halifax for the purpose of inspecting tramcars.

Eastbourne.—The Electricity Committee of the Town Council have decided to discard the German motor omnibus which has for the second time been given a trial. The car has its good points, the arrangement of the body being particularly ingenious and of considerable convenience to the passengers, but its eccentricities were too marked to allow the committee to recommend a definite purchase. One of its little originalities was an impromptu pyrotechnic display, accompanied by a terrific report, which occurred whenever the vapour in the cylinders failed to ignite and the succeeding spark exploded a double charge. One of these performances was given about nine o'clock the other evening just opposite the railway station, and the time in which the passengers vacated their seats and the vehicle is quoted as a record. The crowd which had collected was worthy of the Metropolis, and their remarks were vitriolic. So the committee have determined that the 'bus is too exciting a luxury for staid Eastbourne.

Wallasey.—A tramways extension scheme, estimated to cost £169,100, was adopted by the Wallasey District Council last week. The various routes to be proceeded with were the Poulton-road and Breck-road route, so long asked for, which would cost £14,300; from Breck-road west of St. Luke's Church to School-lane, Wallasey, £8,300; Wallasey village from School-lane to Sandy-lane, £7,100; and Grove-road from Sandy-lane to Warren-drive, £6,600, this completing the Poulton-Wallasey route. In addition to this, there was a doubling in Wheatland-lane, in Victoria-road, New Brighton, a single line along Egerton-street and Grosvenor-road, which would enable some of the cars to go *via* Virginia-road, and would give a double system from New Brighton Ferry to Seabank-road. Also doublings along part of Warren-drive, in Seaview-road, in Hose-side, and along Seabank-road; a single line along Falkland-road, and an extension of the Church-street line along Tobin-street, with a return by a turn-out into Brighton-street, so that a connection with Liscard and Tobin-street could be had for Egremont Ferry.

Lowestoft.—The electric trams, which were only opened on July 22, took as much as £64 and £63 last Saturday and Sunday respectively, which were up to that time record receipts. These figures were far exceeded on Bank Holiday, when, although actually all the cars were not in use, as many as 22,570 passengers were carried (and then hundreds were unable to obtain a ride), and the earnings reached £111. 7s. 4d. The cars were also well filled on Tuesday. The earnings of the cars during the first 12 days (three of which, by the way, were only half days), including about the wettest week of the season, were £729—an average of about £60. 10s. per day. Tuesday night completed the second week's working. In the 14 days the cars have carried 165,900 passengers, a number representing the population of the borough 5½ times over. The takings amounted to £792. 0s. 3d. In the first week, which began after one o'clock on the opening day, and in which there were several rainy days, the number of passengers was 72,434. The number for the second week, which, of course, included the exceptional holiday traffic, was, therefore, 93,466.

Aberdeen.—The traffic receipts for the week ending Saturday, Aug. 1, show that the receipts amounted to £1,251. 1s., a decrease of £68. 9s. 7d. compared with the corresponding week last year. The expenditure for the week, which totalled £490. 3s. 8d., shows an increase of £118. 8s. 8d. compared with the corresponding period last year. There were 33 cars and 210 men employed, as against 31 cars and 142 men in the same week last year, while the number of car miles run was 25,012, compared with 19,758. The passengers carried numbered 285,448, the figures for the corresponding week last year being 292,579. For the nine weeks of the financial year the receipts amount to £11,691. 7s. 10d., an increase of £1 355. 15s. 1d., and as the expenditure for the same period shows an increase of £1,253. 5s. 4d., the net advantage is £102. 9s. 9d. At a meeting of the Lands and Fishings Committee of the Harbour Board an application from the Tramways Committee of the Town Council for a piece of ground for the purpose of providing shed accommodation for the cars to be run on the Torry tramway system was agreed to.

Bury.—At the quarterly meeting of the Town Council Mr. Alderman Sykes, in moving the adoption of the minutes of the Tramway Committee, referred to a hitch which had occurred in the negotiations between the Bury, Rochdale, and other local authorities, and the Bury, Rochdale, and Oldham Tramway Company, by which the understanding that the local authorities should take over the control of the tramway undertaking on July 31 had not come into effect. The hitch, he said, arose through the company springing upon them what the local authorities thought were pettifogging details. He also stated that at a conference between representatives of Bury and Salford on the question of a through service of cars an understanding had been arrived at. During the conference the chairman of the Salford Tramway Committee stated that it had been agreed between Manchester and Salford that any revenue raised by one authority in the other's territory should go into the coffers of that authority after deducting wages, etc. The Salford representatives agreed that the Salford cars should be run on to Bury on conditions similar to those existing between Salford and Manchester. Salford also agreed to run their cars into the centre of Radcliffe provided a double set of rails were laid, Bury to take the revenue. The minutes were confirmed.

Peru.—Two syndicates have recently been formed in Lima for the construction of overhead trolley tramways. One is La Compañia Anónima Tranvia Eléctrico de Lima y Chorrillos. This company proposes to build an electric tramway from Lima to Chorrillos, a distance of about eight miles. The line will be double-tracked and the cars will run at intervals of about 10 minutes. The capital is 389,320dol., divided into shares of 4·86dol. each. The other company is called Ferrocarril Eléctrico de Lima y Callao. This line is also to be double-tracked, and will run from Lima to Callao, about eight miles distant. This company also intends to construct tramways in the city of Callao. Its capital is 486,650dol., and it intends to compete with the existing railways for the carrying of freight as well as passengers between Callao and Lima. The passenger trains are intended to be run, like those of the other company, every 10 minutes. The Government gives to these two syndicates a privilege for 66 years. The two companies are to be free of taxes and are to import free of duty for the term of two years all material for their own use. At the end of 66 years the tramways, rolling-stock, and all material become the property of the Government free of cost. Both the electric tramway companies have made arrangements with American manufacturers for the supply of plant and material to equip the lines, which are to be finished and in working order within two years from the date of contract with the Government.

Tramway Competition.—The Midland Railway, owing to the competition of electric trams, lost 123,000 short-journey passengers during the past half-year. The same cause was answerable on the North-Eastern Railway, in Newcastle, Tynemouth, and Wallsend districts, for a deficiency of 1,000,000 passengers in the same period. At the half-yearly meeting of the Lancashire and Yorkshire Railway Company Sir George Armytage, the chairman, explained the decrease of over half a million passengers carried by the company's trains to be due to the competition of tramways in short journeys. At the half-yearly meeting of the London and South-Western Railway Company Lord Frederick Hamilton, speaking as a shareholder, raised the subject of municipal tramway competition. It was high time, he said, they were protecting their interests. The Chairman, in reply, said the question was under consideration by the Board. He thought their best chance of getting rid of competitive tramways was by fighting them "tooth and nail" when their Bills came before the Houses of Parliament. Tramway competition was also the subject of complaint by Sir Alexander Henderson, M.P., in presiding over a meeting of the Great Central Railway Company at Manchester yesterday. By this competition in the Manchester district alone the company had lost no fewer than 330,000 passengers, but as the majority of these travelled very short distances, and the fares were very low, the actual decrease in receipts would not exceed £2,000 or £3,000.

East Molesey.—At the last District Council meeting the following enquiries were made: (1) whether the London United Tramways Company recently sought to acquire powers to supply electrical energy to private consumers, and electric light for other purposes; (2) whether the Council opposed the application upon the ground that they might at some remote date desire to undertake similar services; (3) whether the powers sought by the tramways company were in any sense exclusive, or whether, on the contrary, they would have left the local authority free to undertake such work whenever they felt so disposed; (4) whether the company were willing to bind themselves not to supply electrical power to any person in the district without the written consent of the local authority; (5) whether opposition of the local authority was prompted not by the consideration that they would be debarred from undertaking work of that kind, but that if they at any time undertook it, they would have to do so in competition with the tramways company. The Clerk explained that it was

Digitized by Google

a fact that they had objected to the tramways company supplying electricity without the consent of the Council in writing, which the company were willing to adopt, but in the passage of the Bill through the House of Commons the whole clause relating to the supply of electricity was withdrawn. It was mentioned that it was the desire of the Council to protect the inhabitants of the district to the fullest extent, and to see that they had a supply of current at the lowest possible price. It must be their policy to come to some arrangement with a company, as they had decided not to provide the supply themselves.

Leeds.—Councillor R. A. Smithson has written to the Lord Mayor of Leeds (Mr. John Ward) resigning his position as chairman of the Tramways Committee. He feels, he says, that no other course is open to him, as it was mainly upon his advice that the Tramways Committee put forward the recommendation in regard to Mr. Hamilton's salary, fully dealt with in our last issue. A special meeting of the Tramways Committee was held on Saturday, at which it was decided to ask the Lord Mayor to write to Mr. Smithson, conveying to him their regret that he should have thought it necessary to send in his resignation. The committee expressed the confidence they have always felt in Mr. Smithson as their chairman. Further consideration of the matter was left over until the monthly meeting of the Tramways Committee next Monday, and a hope was expressed that in the meantime Mr. Smithson would reconsider the position and withdraw his resignation. The Corporation tramway men have been been granted concessions which represent an increased expenditure of £4,600 a year, but it seems in every way likely that they will demand still more, as the minimum, for which they have been agitating has not yet been reached. The tramwaymen connected with the Gas-workers' and General Labourers' Union are not yet satisfied with the new conditions. A meeting was held on the 10th, when it was urged that the whole of their original application to the committee might be granted. The great stumbling block in the way of any final settlement is the bonus system, which, while condemned by the men, is, in the opinion of the committee, the best possible way in which to prevent accidents. They point to the very small number of accidents in the city, contending that if it were not for the bonus system there would not be such a clean sheet in regard to accidents as there is at the present time.

Inquests.—The Salford coroner, Mr. A. Holmes, has held an inquest with regard to the death of the little boy William Pearson, who was killed by an electric car on Wednesday last week. Thomas Griggs, deputy superintendent of the car depôt, stated that the car, which belonged to the Manchester Corporation, was slowing down when he first saw the child. The boy was only some four yards away and he applied the emergency brake and pulled up in 30 yards. With that type of car he could not pull up under about 20 yards. A foreman fitter named Talbot stated that he and Griggs were standing side by side, and the latter was driving the car in a careful manner. The hand brake was applied when the boy was some 20 yards away. The boy was three yards clear of the track, and when the vehicle was about four yards away the boy ran straight in front of it. The car was a big weight—about 15 tons—and going down a decline the weight would carry the car forward. The jury found that death was accidental, and added that they considered the authorities were to blame for entrusting an inexperienced man with the driving of the car.—Mr. Coroner Hoyle held an inquest at the Newcastle Infirmary last week on Mary Etta Rutherford, 20 years old, who was killed by colliding with an electric tramcar whilst riding a bicycle on Monday. The evidence showed that at the point where the accident occurred a large hoarding prevented the driver of the car from seeing traffic approaching from a side street or other traffic from seeing the approach of the cars. It also appeared that the space between the tramlines and the kerb was too narrow for the young woman to turn along it, and therefore compelled her to attempt to cross the road. The coroner commented strongly on the small space that was left between the tramlines and kerbs in various parts of the city. The jury found that deceased had died from injuries accidentally received.

London United Electric Tramways.—The number of passengers carried during the Bank Holiday period was as follows: Saturday, 178,000; Sunday, 200,000; Monday, 330,000; and Tuesday, 170,000—a total of 878,000. For the week ended on Saturday the figures would probably reach 1,100,000 passengers. On Tuesday, on the confirmation of the order for the making of several miles of tramways in the neighbourhood of the Thames Valley, recently passed by the Light Railway Commissioners, the Middlesex County Council asked for amendments by which they should become the purchasing authority in the place of the local authorities through which the tramway passes; that they should have the power to make the by-laws; that all plans of works to be constructed should be submitted to them for approval as well as to the local authorities; and, further, they objected to any light railway being laid unless the roads were 32ft. in width for a single line and 50ft. for a double line. Colonel Yorke, on behalf of the Board of Trade, recommended that the single line should be 32ft. instead of 24ft., as passed by the Light Railway Commissioners. He said that these narrow roads were not suitable for the speeds now attained on tramways; and if the roads were not widened the promoters would have to be satisfied with lesser speeds. Mr. Lewis Coward, K.C., for the tramways company, said if they were saddled with the cost of widening to 32ft., and in some parts to 50ft., they might have to abandon the scheme. The widenings of the London United Tramways route had cost them over £200,000, and it was proposed to make them pay another £100,000. Sir H. Jekyll and the Board would go carefully over that question, and that concerning the change in the purchasing authority, before coming to a decision. The directors of the company have declared an interim dividend of 8 per cent. per annum on the £10 ordinary shares for the half-year ended June 30 last. The divided warrants will be posted on the 14th inst.

North-Eastern Railway.—We have already referred to the proposal of the North-Eastern Railway Company to electrify a portion of their system, notably on the north bank of the River Tyne. The line is at present operated by steam locomotives with the exception of the line from Gosforth to Ponteland, which is under construction. The *Stockton and Darlington Reporter* says the Quayside branch line, which is used for goods traffic only, is also being equipped for electrical operation, the object in this case being to overcome the ventilation difficulties which now prevent the line from being fully utilised owing to it being for the most part in tunnel and on a heavy gradient. The various lines to be so electrified run from Newcastle Central Station in all cases to Manors, Byker, Heaton, Walkergate, Wallsend, Haydon, Percy Main, North Shields, Tynemouth, then up the coast to Monk Seaton, and inland again to Benton, Gosforth, West Jesmond, and completing the circular route. The Quayside line leaves the first route at Byker, and running close to the river, touches the first route again near Percy Main. A third line leaves the original rails at Heaton, and running to Benton, again comes into the circle. The line to be put down runs out west from Gosforth to Ponteland, into what is acknowledged to be pretty country. The current to drive the electric trams will be supplied to the collector rail, from which the cars will collect their power, from sub-stations located at Pandon Dene, Wallsend, Cullercoats, Benton, and Kenton, the largest of these being Pandon Dene. The stations will be lighted with electricity, but the manner in which it will be done has not yet been decided. The new rolling-stock which will be used will comprise motor and trailer coaches, the bodies of which will be built by the railway company at their works at York from the designs of Mr. William Worsdell. They will be of the open-corridor type, lighted and heated with electricity. The unit train will be composed of two motor coaches, with one trailer coach between them, this being strengthened when necessary by the addition of another unit train. The motor coaches will have driver's compartments at one end only, but a master controller will be fitted at the other end also, so that the coach may be driven from this end also. The coaches will be fitted with the Westinghouse air-brake, a motor-driven air-compressor being provided for this purpose. The ordinary stopping train will take about 23 minutes for the journey from Newcastle to Tynemouth, the average speed being 22 miles per hour, including stops. Quick trains, running through without stops, will reduce this time to 15 minutes. Instead of constructing a generating station of their own, the railway company will purchase their current from the Newcastle-on-Tyne Electric Supply Company, Limited. Already many of the contracts have been placed.

LIGHTING AND GENERAL.

Felixstowe.—We understand that the electric lighting is to be started on the 17th inst.

Clydebank.—The new Corporation telephones between Duntocher and Clydebank have been opened.

Friern Barnet.—The Council have decided to apply for an extension of their electric lighting order.

Wednesbury.—The Council have obtained sanction to a loan of £11,000 for electric lighting purposes.

Shropshire and Worcestershire Electric Power Bill.—This Bill has been ordered for third reading.

Morpeth.—The electric supply company will begin to lay the cables in the main streets within a month's time.

Yorkshire College, Leeds.—The next session will begin on Monday, Oct. 5. Details in another column.

Walton-le-Dale.—The District Council have applied for powers to generate and supply electricity in the district.

Scottish Electric Power Bill.—This Bill has passed the Committee on Unopposed Bills of the House of Commons.

Horsham.—An enquiry is to be held into the Council's application for sanction to borrow £9,500 for electric lighting.

Stafford.—The Town Council intend to apply for power to borrow £6,000 for the extension of the electric lighting cables.

Business for Sale.—A well-known electrical plant and accessory supply business is for sale. Details in another column.

Thirsk.—The Parish Council are negotiating with the Northern Counties Electricity Supply Company for public lighting.

Derby.—The Town Council have agreed to pay £3,400 for property in Full-street for the extension of the electric light works.

Kingston.—The appointment of Messrs. Burstall and Monkhouse as advising engineers to the Corporation has been confirmed.

Colyton.—The Parochial Sanitary Committee have decided to at once invite tenders for the lighting of Colyton and Colyford.

Leicester.—The engineer to the Corporation has advised a considerable extension of the distributing plant at a cost of £69,223.

Cardiff.—The work in connection with the electric lighting of Clare-street is expected to be begun in about a week or fortnight.

Whitby.—The Urban District Council have decided to borrow a further sum of £2,500 for extending their electric lighting system.

Conway.—The electric light is to be installed in Deganwy. The Council will consider the question of applying for a Board of Trade order.

Stroud.—The draft agreement with the National Telephone Company for the laying of underground wires within the urban area has been approved.

Malling.—The Kent Electric Power Syndicate and Kent Electric Power Company will apply for orders to embrace the Council's district in the autumn.

Digitized by Google

Bootle.—Mr. W. O. E. Meade-King has held an enquiry into the application of the Council for sanction to borrow £40,000 for purposes of electric lighting.

Redditch.—The Urban District Council are considering a supplementary report from Messrs. Burstall and Monkhouse, London, upon the town's electric supply undertaking.

Carlisle.—The Electricity Committee have appointed a sub-committee to consider the charges at present made to private consumers for the electric current for lighting purposes.

Farnham.—The Urban District Council are corresponding with the Sir Hiram Maxim Electrical and Engineering Company, Limited, with regard to their electric lighting provisional order.

Begnor.—The Local Government Board having given their sanction to the borrowing of £16,000 for the purpose of lighting the town with electricity, the Council are advertising for a loan.

Woolwich.—As the result of the audit by Messrs. W. H. Pannell and Co. of the accounts of the Woolwich Electric Light Company, the Borough Council have benefited by £664. 17s. 7d.

Ludlow.—The Town Council have resolved to apply for sanction to borrow £8,250 for the purpose of carrying out a system of electric lighting for the borough and erecting a refuse destructor.

Mutford and Lothingland.—The Council have asked Messrs. Barber and Croft, of Oulton, to give an estimate for fitting the hospital for the use of electric light, and for the supply of the light.

West Hartlepool.—The Electric Lighting Committee's last report states that 91,581 units of current had been supplied during the quarter ended June 30 against 50,423 for the corresponding quarter of last year.

Walsall.—The Council have entered into an agreement with Messrs. Whittaker Bros., Limited, Dudley, who propose to apply for a provisional order to enable them to supply electricity in the Cannock Urban Council area.

Saltburn.—The work of wiring the parish church for the installation of the electric light is approaching completion, and arrangements have been made for having it switched on on Aug. 30, when special services are to be held.

Fire.—A small fire occurred last Saturday in an outlying store and auxiliary serving shed at Messrs. W. T. Glover's works, Trafford Park, but not of sufficient consequence to affect the output. The damage is only slight, and is covered by insurance.

Spalding.—The Urban District Council have referred to a committee the proposed application of a company to apply for powers to supply the town with electricity, and the question whether the Council d take action to secure the powers for themselves.

Burgess Hill.—The Electric Lighting Committee will, before proceeding further in the matter of electric lighting, enquire as to the probable number of consumers which might be obtained in that portion of the district to be served by the proposed works.

Huntingdon.—We understand that the Town Council will not avail themselves of the offer of the Hiram Maxim Electrical and Engineering Company, Limited, who intend to apply for a provisional order authorising the supply of electricity in the borough.

Northwich.—An offer from the Northwich Electric Light Company as to a suggested fixed price for supplying light for the district is before a sub-committee empowered to confer with either company as to the preparation of a scheme to be submitted by the Council.

Buckfastleigh.—The District Council have accepted an offer from Messrs. Noblett for public electric lighting at 37s. per lamp. The same firm will undertake to light Buckfast on the same terms. They have commenced operations, and the town will be lighted by Oct. 1.

Belfast.—Mr. Moneypenny (most appropriate name in connection with accounts) last week presented the electric accounts, which amounted to £60. 18s. 3d., and stated that the banking account showed a balance of £9,552. 9s. 8d. to the credit of the department.

Wakefield.—The last report of the electrical engineer shows that the income for the year has been £6,669 and the cost £2,846, leaving a gross profit of £3,823. Interest and sinking fund absorbed £2,874, leaving a net profit of £948, a considerable advance on any previous year.

Abersychan.—At Tuesday's meeting of the District Council it was reported that the Empire Electric Light Company were not likely to be successful in their application to supply electric light to the Abersychan district, as the Abersychan Council had already obtained powers.

Lytham.—At a meeting of the Ratepayers' Committee appointed to report upon the question of an electricity installation for the town, on Thursday, it was decided to ask the Council for more definite particulars, so that they may arrive at a conclusion as to what the approximate cost will be.

Peru.—According to the reports of Joseph C. Cree, American vice-consul at Callao, the city of Lima is now lighted throughout by electricity, and in many establishments the machinery is driven by electrical power. A number of the cities in the interior also enjoy the benefits of electric lighting.

Edinburgh.—The number of lamps applied for from July 16 to Aug. 6 was as follows: lighting, 3,559; power, 438; heating, 1,240—total, 5,237; compared with 4,532, 768, and 416—total, 5,716—for the corresponding period of last year. The total for the year from May 15, 1902, was 25,032, and for the year 1983, 23,704.

St. Annes.—Of the £2,866 received from the sale of electric current last year, £1,541. 14s. was from private consumption and £1,324. 15s. 2d. from public lighting. The Council are negotiating a loan of £12,023 for electric lighting extensions. The Electric Light Committee have decided to lay a distributing main in Chapel-street for a distance of 115 yards.

Dorchester.—The Town Council again considered the question of electric lighting on Tuesday. Messrs. E. Wright, the electrical engineers, had informed the Council that they were prepared to submit a modified scheme to serve the compulsory area at an expenditure of from £12,000 to £14,000 in place of the more expensive scheme they had already submitted.

London Gazette.—The partnership heretofore subsisting between Ralph Ball and Sidney Alfred Hunter, carrying on business as dealers in electrical accessories, at 9 and 10, Wells-street, Oxford-street, in the county of London, under the style or firm of the Accessories Manufacturing Company, has been dissolved by mutual consent as and from July 31, 1903.

New Book.—We have received from the Directory Publishing Company, Limited, 3, Ludgate-circus-buildings, E.C., the ninth issue of the "Universal Directory of Railway Officials," compiled from official sources under the direction of S. Richardson Blundstone, editor of the *Railway Engineer*. The volume is, like its predecessors, well compiled and handy for reference.

Ludlow.—At the last Town Council meeting it was decided to apply for sanction to borrow £8,250 for carrying out a scheme of electric lighting and for the purpose of a refuse destructor. The scheme has been prepared by Mr. John Parker, Hereford, and the Corporation has already consulted an expert upon the details, his opinion being entirely favourable.

Swinton and Pendlebury.—The clerk (Mr. Postlethwaite) has been instructed to write to the Lancashire Electric Power Company and the South Lancashire Tramways Company enquiring when these companies would be prepared to enter into an agreement to supply electricity in bulk for the lighting of the district, and on what terms, if different from the offers already made.

Clacton.—At the last meeting of the Urban District Council a letter was considered from Messrs. Ainslie Bros., Electric Works, Pier-avenue, undertaking to supply electrical energy and a business premises, etc., in the centre of the town, by arrangement with the Council, on the understanding that the Council should take over the installation at the end of seven years at cost price.

Battersea.—Tenants of the Borough Council's new workmen's dwellings on the Latchmere estate will be able to use electric light at a charge less than the price of gas which rules in the disirict. The electric light will be provided on the "penny-in-the-slot" system at the rate of 4d. per unit. The arrangement means that about 7½ hours' light from one ordinary 8-c.p. lamp can be obtained for 1d.

Bexley.—We understand that Messrs. Mordey and Dawbarn have been appointed the Council's consulting engineers with regard to the electric lighting of the newly-added East Wickham ward. It further recommends the Council to instruct the engineers to prepare plans and detailed estimates of the cost of lighting of that ward, in order that same may be submitted to the Local Government Board with application for loan.

Beverley.—The Beverley Corporation and Mr Baker, the engineer employed in connection with the scheme for installing the electric light in the borough, have agreed to refer the payment of Mr. Baker's account to the president of the Law Society, or someone he may appoint. This means the abandonment of the scheme by the Corporation, and the settling of the electric lighting question for some years to come.

Sowerby Bridge.—A circular is to be sent to the various mill-owners, tradespeople, etc., within the area covered by the electric lighting order, asking if they would be prepared to take a supply of electricity from the Council, and also what quantity they would be likely to require. A sub-committee has been appointed to consider generally matters connected with electric lighting and the carrying out of the order.

The King's Electric Motor-Launch.—On Thursday last week the King and the Prince of Wales left the Royal yacht in his Majesty's new electric motor-launch, used for the first time on this occasion, and landed at Kingston Quay. A visit was then paid to Barton Manor, a large residence on the Osborne Estate, where alterations have been in progress with a view, it is believed, to its being utilised by members of the Royal family.

Accrington.—The Electricity Committee have adopted a new scale of electricity charges both for lighting and power, commencing on Oct. 1 next—viz.: Lighting—4d. per unit, with 1¼ per cent. discount for 251 up to 500 units per quarter, rising by 1¼ per cent. for each additional 250 units up to 3,000, over 3,000 units 15 per cent. Power—3d. per unit for the first hour per day of normal full-load running, and 1d. per unit after. No demand indicator is to be used.

Accidents.—On Wednesday an accident occurred on the tramway route near the centre of the town, by which about 16 persons were injured, 12 of which required medical treatment. It appears that a car proceeding from Margate had reached the top of the hill in Bellevue-road, when an overhead rod became detached from the cable and the driver lost control of the vehicle. It ran down hill at a most alarming rate, and would possibly have stopped without mishap had not another car been on the rails at a point where the lines converged. The cars collided with violence, and all the outside passengers were thrown off. From the evidence at the enquiry into the accident which occurred in Elswick-road, Newcastle, last week, it appears that no blame could possibly be put on the driver of the car, who did the best he could under the circumstances. Some excitement was caused in Church-street, Liverpool, near the Pro-Cathedral, on Monday through one of the electric tram wires falling into the roadway. No one was injured, and the Corporation repairing wagon, which arrived in quick time repaired the damage within half an hour.

Digitized by Google

South Staffordshire Mines Drainage.—At the last meeting of the South Staffordshire Mines Drainage Commission, Mr. E. B. Marten, surface engineer, reported that the electric pump at Doebank had worked continuously during the last month. We understand that further electric pumps are to be installed.

West Bromwich.—The loss for the year on the electric lighting account amounts to £1,045. 5s. 2d. The sum of £760 will be transferred from district fund to credit of profit and loss account, which at March last stood at £1,195. 1s. 2d. The Council have adopted the report on street-lighting to which we referred in our last issue.

Rochester.—The surveyor has been instructed to build a boundary wall and iron fence to enclose the yard adjoining the central station at a cost of £107. The electrical engineer (Mr. A. R. Sillar) in his last report gives the following figures: output of electricity in units during June—1903, 13,113; 1902, 8,266; 1901, 4,464; number of consumers at end of June—1903, 362; 1902, 279; 1901, 177; total number of 8-c.p. lamps connected—1903, 22,819; 1902, 16,483; 1901, 12,691.

Glasgow.—The accounts of the Corporation Electricity Committee show a revenue of £127,000, an increase on the 12 months of £24,000. Generating and distribution cost £57,500, and provision was made for interest and statutory sinking fund to the extent of £45,000, leaving a balance of £24,500. For depreciation applicable to the year the committee have, however, written off £37,700, thereby bringing out a net debit balance of £13,200. No alteration will be made in the charges to consumers.

Perth.—Mr. John Lambert, electrical engineer, has just issued his report on the working of the electrical department for the month of July, giving the following figures: units generated during month, 23,764; units generated during same month last year, 8,434; consumers connected, 4; lamps connected (equivalent), 154; lamps disconnected (equivalent), nil; total lamps connected since June 1, 1901, 24,461; coal and coke used during month, 112 tons 3cwt.; coal, etc., per unit generated, 10·57lb.

Wakefield.—The city electrical engineer (Mr. C. M. Shaw) in his report upon the electric light shows a net profit for the past year of £948, compared with £187 in 1902, £463 in 1901, and £129 in 1900, while in 1903 there has been an increased consumption of 47 per cent. over that of the preceding year, and an addition of 48 per cent. to the lamp connection of 1902. The increased profit is owing to economies effected and improvements made at the works, as well as to an increase of the output, while there is no appreciable increase in the expenses for buildings, salaries, and so forth.

Sunderland.—The electric lighting account shows a total borrowing of £226,635 and an expenditure of £225,997 on capital works, £26,214 of which had been spent during the year. The income on the revenue account was £31,325, and the working expenses were £18,509, leaving a gross profit of £12,816 to carry to net revenue, out of which there has been paid in interest £6,755, and £6,460 has been set aside for the depreciation and sinking fund account. The total amount repaid to mortgages was £20,025, and £1,346 has been set aside for reserve purposes.

Worthing.—Electricity equivalent to 11,955 lamps of 8 c.p. is now supplied by the Corporation to private consumers, who number some 230, and there are still connections to be made. There was a recommendation to the Town Council on Tuesday to acquire the land and premises on the east side of the electricity works, "on the ground that it would be a material advantage to extend the frontage of the works to Park-road, and admit of the shutting off of that part of the present premises which is in use for other purposes." The proposal to purchase was, however, rejected.

Lowestoft.—The Electric Lighting Committee's estimate for the half-year ending Dec. 31 shows that they will probably require £894 from the rates to meet expenses, which includes £2,350 repayment of loans and interest and £1,700 for coal. The electrical engineer reports that 10 new consumers for the last month, representing 507 8-c.p. lamps, had been connected to the mains. The total lamps connected aggregate 20,218 8-c.p. lamps. Cables for public lighting are being laid in Essex-street and Norfolk-road to enable the surveyor to complete the making-up of these roads.

Ayr.—The burgh electrical engineer (Mr. Roland Marshall) in his last report says the sub-station at Craigie-road is now completed and equipped, and so far is working satisfactorily. The erection of a sub-station is in hand. The following figures were appended: Number of consumers as per last report, 707; number of consumers connected during month, 6—total, 713. Number of lamps connected as per last report, 27,243; number of lamps connected during month, 391—total, 27,634. Units generated as per last report, 104,476; units generated during month, 62,752—total, 167,228; units generated for corresponding period of last year, 164,819—increase, 2,409.

Sheffield.—The chief constable recently interviewed the general manager of the electric light department and the cleansing superintendent with reference to the utilisation of the spare steam at the Penistone-road destructor for the purpose of generating electricity for lighting streets in the neighbourhood of the destructor. The estimated cost of the installation of the necessary plant, lights, etc., for lighting 100 lamps would be £3,000—not including the annual cost of maintenance. A deputation from the Watch Committee will meet the Cleansing Sub-Committee of the Health Committee with reference to the utilisation of the spare steam for the purpose named.

Chesterfield.—Application is to be made for sanction to borrow £15,000 for the extension of the electricity works. The consumers and the plant have increased from time to time, and the major part of the proposed loan is to be used for paying work already sanctioned by the Council, leaving a margin for further extensions. In June, 1903, there were 262 consumers, as compared with 146 in 1902; an equivalent of 21,132 8-c.p. lamps, as against 11,676; 161 h.p. in motors, as against 30; 16 radiators, as against 10; and 43,313 units sold, a compared with 22,919. The revenue from current sold for the quarter ended June, 1903, was £802, being an increase of £319. 15s. 10d.

Water Power in the States.—In the United States 43 companies, having a total capacity of 177,300 h.p., transmit power over a line distance of 1,549 miles, on an average 36 miles, with a voltage which ranges from 10,000 to 60 000 volts. The maximum distance over which power is transmitted is from Colgate to San Francisco, 220 miles, with a loss of 25 per cent. Waterfalls are made use of under the most varied conditions as regards volume and fall. At Niagara the body of water is large, and the fall is between 150ft. and 200ft.; at Sault Ste. Marie, between Lakes Superior and Huron, the body of water is also large, but the fall is small—namely, 24ft.; at Colgate the body of water is small, but the fall is 1,500ft.

Tonbridge.—The Electric Lighting Committee in their last report state that the total amount of charges to private consumers for the quarter ending June 30 were £107. 11s. 1d. The resident engineer reported that five applications for light had been received during the month, and that the total to date was 72, equal to 2,395 8-c.p. lamps. The number of units supplied to private consumers for the quarter ended June 30 (summer quarter) was 5,280, against 5,546 for the quarter ended March 31, 1903 (winter quarter). The consumption for a winter quarter was usually double that for a summer quarter, and the resident engineer therefore estimated that at least 12,000 units would be sold for private consumption during the next Christmas quarter.

Brighton.—The following proceedings of the Lighting Committee have been confirmed: "This committee, at their meeting on July 27, had before them a letter from the British Westinghouse Electric and Manufacturing Company, Limited, stating that they made a mistake when they quoted the sum of £580 for electrically-driven condensers, instead of steam-driven, in the works at Southwick, and that the price should be £1,400, as quoted in their letter of June 6, 1903, forwarding their tender for the generating plant The consulting engineer having reported thereon, the committee were satisfied that the smaller sum was quoted in error, and they recommended the Council to agree to pay £1,400 as the addition for electrically-driven condensers."

Broughty Ferry.—The Town Council have adopted the following charges for current: for motive power, 4d. per unit; for lighting, 6d. per unit. The accounts of the electricity department show receipts amounting to £706. 9s. 7d. and expenditure to £887. 13s. 7d., a deficit of £181. 4s. The sale of current realised £688. 10s. 6d., the amount derived at 6d. per unit being £485. 5s. The expenditure consisted chiefly of the cost of generation, £351. 18s. 11d., and management expenses, £228. 12s. From the estimates it appeared that the sale of current was expected to yield £1,673. 13s. 4d., and that the total income would be £1,694. 8s. 4d. The generation, it was anticipated, would cost £402. 7s.; management expenses, £241; while interest and sinking fund would absorb £421. 17s. 6d. and £443. 11s. 3d. respectively, the total outlay being estimated at £1,628. 13s. 11d., exclusive of the debit balance at the beginning of the year.

Longton.—The last report shows that the electric lighting undertaking is more satisfactory, even at this early stage in its career, than was anticipated, though it does not pay the whole of the charges to be brought against it. There is a "working profit" of £704 for the year ended March last, but the interest on capital and the proportion of sinking fund not only swallow up the whole of the working profit, but also leave a deficiency of £719. This, with a similar deficiency of £426 on the previous year, leaves a net deficiency of £1,145 on the 18 months' working. There was an item of £870 for bank interest. It will probably be three or four years before the profit from this department will be sufficient to meet the whole of the current capital charges, and in the meantime there will be an increased deficiency in the sinking fund account. the debit balance at the present time being (as stated before) £1,145, and probably nearly £3,000 before the committee can make ends meet.

Siberian Telegraphs.—The *Globe* St. Petersburg correspondent says the recent decision of the Imperial authorities to establish direct telegraphic communication between St. Petersburg and Vladivostock may be ascribed, doubtless, to the following incident. A few days ago there arrived here a very important telegram consisting of 1,600 words, and sent from Japan to the Czar by means of the Siberian telegraph system. Not only did the telegram take three days to reach the Russian capital after it had been dispatched, but on its arrival it was found to be so greatly mutilated that its meaning was altogether unintelligible, and the dispatch was valueless. The Czar at once gave orders that the chief officials employed in the postal and telegraphic offices at Irkutsk, Blagovestshensk, Vladivostock, and Samara should be dismissed. Nor will the matter rest there; it is reported that the chief officials of the Siberian telegraphic system as far as Kazan, in European Russia, are to be removed from office.

Hull.—The last report by the city treasurer and Mr. Bell (acting engineer) shows the position of the electric light undertaking. The value of the useful plant is estimated at £220,000, after deducting the cost of plant disposed of, the depreciation set aside on meters, and the proportion of accumulated sinking fund. The statement shows that the land in Dagger-lane cost £152. 10s., and that in Sculcoates-lane £1,348. 16s. 6d. The buildings in Sculcoates-lane have cost £21,285, in Dagger-lane £3,175, and the sub-stations £1,196. The engines and dynamos at Dagger-lane cost £9,296, and Sculcoates-lane and sub-stations £33,887; the boilers and economisers at Dagger-lane £2,266, and at Sculcoates-lane and sub-stations £8 072; while the transformers and other plant and works have cost £11,579 at Dagger-lane, and £35,946 at Sculcoates-lane and the sub-stations. The accumulators have cost £2,340, and there have been expended £113,377 on mains, and meters have cost £11,229. The total expenditure has been £252,545, the

Digitized by Google

increase during the year being £46,299. The number of units sold for the year ending March, 1903, was 2,385,577, as compared with 1,490,099 in the previous year, the receipts being £31,148, an addition of £7,591.

COLONIAL NOTES.

Ladysmith.—The Corporation's electricity plant has now been erected, and a trial run is expected to be made in the early part of this month.

Melbourne.—Mr. Alfred Edward Morgans, of Perth, has obtained a contract for the construction of electric tramways in some of the suburbs. The contract stipulates that building of the generating station is to be commenced three months after the powers required by the contract have been obtained. The station is to be finished within nine months, and the service is to commence 12 months after that date.

Tamworth (N.S.W.).—Tamworth was the first town in New South Wales to be lighted by electricity, and the municipal plant installed by Messrs. Crompton and Co. has been in constant use for the past 15 years. The Council are at the present time considering the question of private lighting, and a canvass was recently made of the town to find out what amount of support would be forthcoming if the light was made available for private use. The result was most satisfactory, and orders were taken for the equivalent of over 2,000 8-c.p. lamps. Mr. William G. Counsell, the borough electrical engineer, will shortly submit for the Council's consideration a scheme providing for the necessary extensions to plant, and if this scheme is adopted, the motive power will be producer gas, working in conjunction with gas-engines. The estimated capital expenditure will be about £6,000.

PROVISIONAL PATENTS, 1903.

JULY 27.

16456. **Improvements in the manufacture of incandescence electric lamps.** Harry Hogge and Jean Barrollier, 115, Cannon-street, London. (Date applied for under Patents Act, 1901, April 8, 1903, being date of application in France.) (Complete specification.)

16469. **Electrical fog signalling apparatus.** O'Brien Reynolds St. John Palmer, 50, Melton-terrace, New Hartley, Northumberland.

16481. **Improvements in and connected with apparatus for electrically locking railway carriage doors.** William Walmsley, 9, Tempest Hey, Liverpool.

16467. **Improved telegraph pole.** Wilhelm Schütz, Dresden—A. 3, Germany. (Complete specification.)

16509. **Improved field magnet for electrical machines.** Thomas Alfred Hearson, 22, Southampton-buildings, Chancery-lane, London. (Electricitäts-Gesellschaft Alioth, Switzerland.) (Complete specification.)

16511. **Improvements in electric hoist controllers.** William Harding Scott, 47, Lincoln's-inn-fields, London.

16513. **Improvements in and relating to electrical fuses or cut-outs.** William Richard Macdonald and George Edward Heyl-Dia, 322, High Holborn, London.

16514. **Improvements in indicating devices for use with electrical fuses or cut-outs.** William Richard Macdonald and George Edward Heyl-Dia, 322, High Holborn, London.

JULY 28.

16534. **Improvements in and relating to secondary galvanic batteries.** Max Schneider and Julius Beissbarth, 51, Deansgate-arcade, Manchester.

16594. **An improved process for making fireproof casings and covers for electric conductors.** Henry Redmayne Romney, 65, Chancery-lane, London.

JULY 29.

16636. **Improvements in insulator brackets for telegraphic or telephonic purposes.** Charles Henry Brandreth, Imperial-chambers, Albert-street, Derby.

16653. **Improved apparatus for soldering armature leads to commutator bars.** John Alexander Wirth and Jacob Beech, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Oct. 22, 1902, being date of application in United States.) (Complete specification.)

16661. **Improvements in and relating to electrical heating devices.** Milton Henry Schoenberg and James Washington Edwards, 60, Queen Victoria-street, London. (Complete specification.)

JULY 30.

8576A. **Improvements in or connected with the rail return and the utilisation of the current therein on electric tramways.** James Townsley Pearson, 8, St. James's Hall, Burnley. (Date applied for under Patents Rule 9, Feb. 16, 1903.) (Complete specification.)

18711. **Insulators for electrical terminals.** John Alfred Davenport and Arthur Frederic Guy, 10, St. George's-crescent, Liverpool.

16740. **Improvements in time-limit electric circuit controllers.** Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

16741. **Improvements in electric arc lamps.** Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

16742. **Improvements in electric cut-outs or switches.** Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

16744. **Improvements in controlling electric switches.** Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

16745. **Improvements in controllers for electric motors.** Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

JULY 31.

16774. **Improvements in converting electric currents.** Granville Hugh Baillie, 82, Victoria-street, Westminster, London.

16788. **Electric integrator.** William Bullen Day, K Lines, Curragh Camp, co. Kildare.

16806. **Improvements in electrical fuses, ceiling roses, and wall plugs, and method of attaching metal terminals thereto.** James Morton Douglas, 5, Budge-row, London. (Complete specification.)

16808. **Improvements in or connected with holding devices for the collecting brushes of electrical machines.** Griffith Brewer, 33, Chancery-lane, London. (Electricitaets-Gesellschaft Alioth, Switzerland.) (Complete specification.)

16817. **Improvements in dynamo-electric machines of the class employing commutators.** Henry Metcalf Hobart, Oswaldestre House, Norfolk-street, Strand, London.

16830. **An improvement in connection with the trolley wheels of overhead-driven electric vehicles.** William Charles Dunne and Louis Levitt, 23, Coleman-street, London.

16836. **Improvements in and connected with lampholders for electric incandescent lamps.** Ferdinand Subatzus, 81, High Holborn, London.

16852. **An improvement in flexible metallic tubing for armouring electrical conductors and apparatus for its manufacture.** William Henry Kanzon Bowley, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

AUGUST 1.

16856. **Improvements in electrostatic methods of measuring electrical potential differences.** Edgar Walford Marchant and Gladstone Walker Worrall, Liverpool University, Liverpool.

16868. **Improvements in portable accumulators.** Harry Ramsbottom and Jasper Richardson, 427A, Strand, London.

16878. **Improvements in and relating to printing telegraph instruments.** Clarence Mortimer Stiner, 51, Deansgate-arcade, Manchester. (Complete specification.)

16902. **Improvements in electric fuses.** Edward Neville Bray, Frederick Rice Markham, Ferdinand Edward Reiss, and Bray, Markham, and Reiss, Limited, 18, Southampton-buildings, Chancery-lane, London.

16907. **Improvements in controllers for electric-motors.** John Bush, 90, Lausanne-road, Peckham, London.

AUG. 4.

16960. **Improvements in or relating to balance weights for electroliers, lamps, pendants, and the like.** William Soutter, 82, Mark-lane, London.

16965. **Improvements in electrical fire-alarm apparatus.** James Percival Robertson, 77, Chancery-lane, London. (Complete specification.)

16975. **Improvements in electrical cut-outs.** Hugo Korten, 80, Leicester-road, East Finchley, London.

16988. **Improvements in or relating to partitions or diaphragms for electrolytic and electro-plating purposes.** Pierre Steenlet, 111, Hatton-garden, London. (Complete specification.)

16989. **Improved process for obtaining copper by electrolysis from copper-containing solutions.** Pierre Steenlet, 111, Hatton-garden, London. (Complete specification.)

16992. **Improvements relating to electrolytic cells.** Phillippe Auguste Gaye, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

17001. **Automatic electric stopping apparatus for lace and net machines.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, Chancery-lane, London. (Auguste Pocheron and François Cellery, France.)

AUG. 5.

17034. **Induction transformer for wireless telegraphy stations.** Eugéne Ducretet, 72, Cannon-street, London. (Complete specification.)

17057. **Improvements in and relating to steering gear for motor road vehicles, electric or steam launches, and the like.** Thomas Mathewson and Arthur James Fielding, 11, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17059. **Improvements in incandescent filaments for electric incandescent lamps.** William Phillips Thompson, 6, Lord-street, Liverpool. (Bayerische Glühfadenfabrik Augsburg-Lechhausen Georg Luedecke und Co., Germany.)

Digitized by Google

17069. Improvements in geometric telegraphs. Grant Beebe Rossman, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17072. A method of sytonising two electric circuits and apparatus for use therein. Christopher Russell Payne, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17073. Improvements in electric arc lamps. Thomas Hamilton-Adams, 4, South-street, Finsbury, London.

AUG. 6.

17082. Improvements in the manufacture of trolley poles and means for connecting them to trolley standards in trolleys used for electric tramcars or vehicles propelled by electric traction. Edward May Munro, Henry Brecknell, and Hugh Innes Rogers, Thrissell-street, Bristol.

17105. Improvements relating to insulating supports for use in electric traction systems. Domenico Bordoni, 45, Southampton-buildings, Chancery-lane, London.

17128. Improvements in means for electric signalling between railway trains and between railway stations and trains. Marius Archambault, 47, Lincoln's-inn-fields, London.

17140. Improvements in electromagnets. Frederic de Mare, 72, Cannon-street, London.

AUG. 7.

17149. Improvements in electric traction on a shallow conduit system. Samuel Green Bennett, Clyde House, Heath Town, Wolverhampton.

17150. Improvements in or connected with switches for starting electric motors. Alfred Sykes, 32, John William-street, Huddersfield.

17173. Improvements in electrical starting gates for race-courses. Herbert Fraser Foster, "Turnlee," Laburnam-road, Epsom.

17179. Improvements relating to electric railway systems. Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Morgan Electric Machine Company, United States.) (Complete specification.)

17184. Improvements in clamps for wires, especially applicable for use in overhead electric conductors. Franz Krückl, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17185. Improvements in frames for alternating-current motors. Giorgio Finzi and Emil Korrodi, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17195. Improvements in and relating to wireless telegraphy. Octave Rochefort and Emile Mors, 45, Southampton-buildings, Chancery-lane, London.

17207. Improvements in or connected with dynamo-electric machines. Thomas Murthwaite Dutton and the Sandycroft Foundry Company, Limited, 6, Lord-street, Liverpool.

17214. Improvements in protecting devices for electric circuits. William Bradley Woodhouse, 18, Southampton-buildings, Chancery-lane, London.

AUG. 8.

17225. Improved interlocking automatic intercommunication telephone switchboard. Frederick James Lowe, 5, Pearson-terrace, Hyde Park, Leeds.

17229. An improved appliance for gripping and supporting the wires of overhead wire systems of electric traction. John Henry Luby and William Harris, Lloyds' Bank-buildings, Bristol.

17232. Improvements in terminal holders for electric wires, leads, or cables. Charles Henry Stevens, Lloyds' Bank-buildings, Bristol.

17241. Device for re-railing electric or steam tramcars which have accidentally left the lines. Joe William Harrop, Tom Dickinson, and Harry Dickinson, 7, Ray-street, Huddersfield.

17245. Improvements in electric light fixtures. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

17247. Improvements in electric light fixtures. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

17248. Improvements in electric rheostats. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

17249. Improvements in reels for electric cables and the like. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

17272. A new or improved device for electrically firing blasting cartridges and the like. Thomas Grainger, 9, Regent-street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published August 27, 1903.

INTERNAL-COMBUSTION ENGINES FOR DRIVING DYNAMOS.*

BY HERBERT A. HUMPHREY, M.I.C.E., M.I.E.E.

There are now 50 firms manufacturing large gas-engines of 200 h.p. and upwards. Almost all these firms have entered this new branch of engineering during the last five years, and the large gas-engines now running have been constructed, with but few exceptions, during the last 3½ years. The table attached to this paper shows the number of gas-engines above 200 i.h.p. made by some of the principal firms. The engines now completed or on order number 498, having an aggregate capacity of 310,865 h.p., and of these 390 engines are for dynamos, and give collectively 198,405 i.h.p. The central-station engineer is now fully alive to the fact that the gas-producer and gas-engine constitute the cheapest means of generating electric power where coal is the basis of the energy. The internal-combustion engine is rapidly attaining to sizes of units which are large enough to suit even the big tramway stations, and, when suitably designed, has proved quite as reliable for driving alternators in parallel as the best steam-engine.

The following types of gas-engines are now made for driving dynamos, and figures are added showing the number of impulses per revolution and the horse-power up to which each type is constructed. Single-cylinder single-acting gas-engines, although made in large powers (600 h.p. to 700 h.p.) by the John Cockerill Company, of Seraing, and by Messrs. Richardsons, Westgarth, and Co. in this country, would not usually be chosen in large units for dynamo driving, except where regularity is not important. It is interesting to note, however, that 100-h.p. gas-engine sets of the single-cylinder single-acting type are actually in use at the Embrach Works, driving belt-driven three-phase alternators in parallel, a small additional flywheel being placed on the armature of each machine.

	—	Impulses per revolution.	Usual sizes of engines.	Reference No.
Four-stroke cycle single-acting	Single cylinder	½	Up to 600	1
	Vis-à-vis	1	,, 600	2
	Double *vis-à-vis*	2	,, 1,200	3
	Twin cylinder	1	,, 800	4
	Tandem cylinder	1	,, 1,200	5
	Double tandem	2	,, 2,500	6
	Vertical two, three, and four cylinder	1, 1½, 2	,, 1,000	7
Four-stroke cycle double-acting	Single cylinder	1	,, 1,000	8
	Twin cylinder	2	,, 1,000	9
	Tandem cylinder	2	,, 2,000	10
	Double tandem	4	,, 4,000	11
	Vertical two cylinder	2	,, 2,000	12
Two-stroke cycle single-acting	Oechelhauser, one cylinder	1	,, 1,000	13
	Oechelhauser, two cylinder	2	,, 2,000	14
Two-stroke cycle double-acting	Korting, one cylinder	2	,, 2,000	15

One of the first types to gain prominence was the *vis-à-vis* engine, manufactured by Messrs. Crossley Bros., who make engines of 500 h.p. and 600 h.p., with two cylinders, and the Gasmotoren-Fabrik Deutz, who have carried this type up to 1,200 h.p., using four cylinders. Probably no more engines of this type will be made on the Continent, as the Deutz firm have abandoned the design in favour of double-acting single and tandem-cylinder engines. Consequently, although this *vis-à-vis* type has done excellent service, and is now in use for driving alternators in parallel on a large scale, little need be said about it in face of the change to the double-acting type which is taking place.

Type No. 4 is being made by Körting Bros., of Hanover, who get about 300 h.p. to 400 h.p. out of each cylinder, the two cranks being placed at 180deg. This type is going to be largely adopted, but the tandem engine (type No. 5), with its straight-line stresses and equally-timed impulses, is likely to live longer than the *vis-à-vis* type or the twin-cylinder type. The Premier engine is an example of the straight-line type, and the Premier Gas-Engine Company have held a front place among the pioneers in large gas-engines. The Nürnberg Company and the Cockerill Company also make very powerful engines of the ordinary tandem type, suitable for direct coupling to both direct-current dynamos and alternators. The double-tandem engine (type No. 6) can be carried to very large powers, and makes a simple and strong engine, but it is heavy for its work and covers a large floor space. Very good work has, however, been obtained from this engine, and it is suitable for driving alternators in parallel up to units of 2,500 h.p.

Quite a number of firms now manufacture vertical gas-engines with two, three, or four cylinders (type No. 7), all of them constructed specially for dynamo driving. The Westinghouse Company are the best-known makers in connection with this type of engine, but Messrs. Tangyes, Limited, and Messrs. the Campbell Gas-Engine Company now construct vertical engines up to 300 h.p. and 400 h.p. The last-mentioned company make a four-cylinder vertical engine which is extremely well balanced, and, as it gives two impulses per revolution, provides great regularity of turning moment. Messrs. Fielding and Platt have made their first four-cylinder vertical engine, enclosed type, and expect a number of orders for engines of 100 h.p. to 200 h.p.

Many attempts were made to get over the difficulty of a piston-rod stuffing box, and Messrs. Dick, Kerr, and Co. years ago constructed and ran at Belfast engines with double-acting pistons and piston-rod glands. The solution of the problem has, however, come gradually, and the Cockerill Company, followed by numerous other makers, have now examples of efficient stuffing boxes fitted in the closed ends of gas-engine cylinders and giving no trouble. Once this difficulty is removed, the gas-engine must logically be manufactured as a double-acting machine, for by simply duplicating the valve gear twice the power and twice the number of impulses are obtained from the same size of cylinder without increasing any of the working stresses. So completely has this fact been recognised, that all the leading makers now construct double-acting engines (types 8 to 12), and powers of 1,000 h.p. with single-cylinder engines, and of 4,000 h.p. with double-tandem engines, of the double-acting type, are readily obtainable. Nearly all the important orders which are now being placed for large gas-engines are for the double-acting type, and all the types Nos. 8 to 12 give thoroughly efficient prime movers for central-station work. In fact, the tandem-cylinder engine (type No. 10) and the vertical two-cylinder engine (type No. 12) are among the chief favourites on the Continent and in this country. The Nürnberg Company and the Deutz Company build double-acting tandem engines which leave very little to be desired in the way of simplicity, smooth running, and good turning moment qualities.

The Nürnberg engine has the whole of the weight of the piston and piston rods carried on slides running on guides, so that the piston and stuffing-box friction is reduced to that due simply to the rubbing contact on the piston rings and the packing in the glands. The front slide constitutes the ordinary cross-head, and the back slide block is utilised to introduce and discharge the water required for cooling the pistons and piston rod. This type of engine has so far reached the lowest consumption of both gas and oil for a given output of power.

The new type Westinghouse gas-engine now being made in this country for powers of 500 h.p. to 2,000 h.p. has much the appearance of the vertical Corliss engines so largely used in the United States. The two double-acting Otto-cycle cylinders are carried on A-frames, and the connecting rods are coupled to overhanging crank-pins at either end of the shaft, so that only two large bearings are required. Between these bearings the alternator and flywheel are placed, and the whole forms a very compact and powerful set, occupying the minimum floor space and running at speeds closely corresponding to the usual speeds of similar size steam units used to drive large alternators.

The Oechelhauser engines have been largely built for dynamo driving by the Deutsche Kraftgas-Gesellschaft, and one of their finest examples is to be found in the central power station at Ilsede Hütte, where electric power is developed by gas-engines coupled to alternators, and supplying three-phase current at 10,000 volts to rolling-

mills at Peine, about five miles away. The gas-engine sets are in 1,000-h.p. units, and run in parallel with steam-driven alternators, but the latter are to be superseded when the full 6,000 h.p. of gas-engines—*i.e.*, six units—is installed.

Last, but not least, we have the Körting gas-engine, which heads the list with the highest aggregate of power of any type. It is the only engine at present on the market which gives two impulses in one cylinder per revolution, being in this respect like an ordinary steam-engine. Many firms have taken out licenses to build this engine, and in this country it is made by Messrs. Mather and Platt, who have just supplied their first 700-h.p. engine for dynamo driving, and by Messrs. Fraser and Chalmers. Full descriptions of the Körting and Oechelhäuser engines have appeared in the technical journals, and these types are now almost as well known as the Otto-cycle engines.

Brief mention must be made of the Vogt gas-engine, which, like the Körting engine, gives two impulses per revolution in one cylinder. It is unique, in that the explosions take place over water, and the motor cylinder is filled with this fluid. The combustion chambers are above the cylinder level, and the water rises and falls in these as the piston reciprocates. This engine embodies the principle of internal cooling, so that water jackets are dispensed with, and the metal cylinder may be made as thick as strength requires for any size of cylinder. No hot gases come in contact with any moving part of the engine except the valves. Probably a good deal will be heard of this engine

in the future, as the results obtained with an experimental engine of small size are excellent.

In the author's opinion sufficient attention has not been given to the construction of gas-engines intended to take a supply of both gas and air, separately stored under pressure. For central stations of large size the previous compression of the gas and air, so that they may be drawn as required from reservoirs, has much to recommend it, and involves, with proper precautions, no special danger. The advantage of the two-cycle gas-engine would then be attained without the complication of each engine carrying its compressing plant, together with all the extra valves and gear required. Also, there is no reason why the heavy and somewhat noisy cam gear on gas-engines should not be replaced, and the valves operated by compressed air, or even high-pressure burnt gases stored from the motor cylinder itself, controlled by a small rotating valve.

The term "internal-combustion engines" embraces oil-engines, but oil-engines above 200 h.p. are rare, and cannot compete in cost of fuel with gas-engines using cheap producer gas, especially when the system of recovering the ammonia from the coal, as in the Mond producer plant, is available. The Diesel oil-engine has attained a high degree of economy, and has been applied to dynamo driving up to 200-h.p. units.

In general, a gas-engine giving at least one impulse per revolution is necessary for all central-station direct-coupled dynamo sets, and in cases of alternators working in parallel

Digitized by Google

engines should be chosen which give two impulses per revolution. The exact solution of the alternator-in-parallel problem is too complicated, owing to the interaction of the sets, to be given here, but some idea of the relative value of different types of engines for this class of work can be gathered from the Klönne diagrams, which take no account

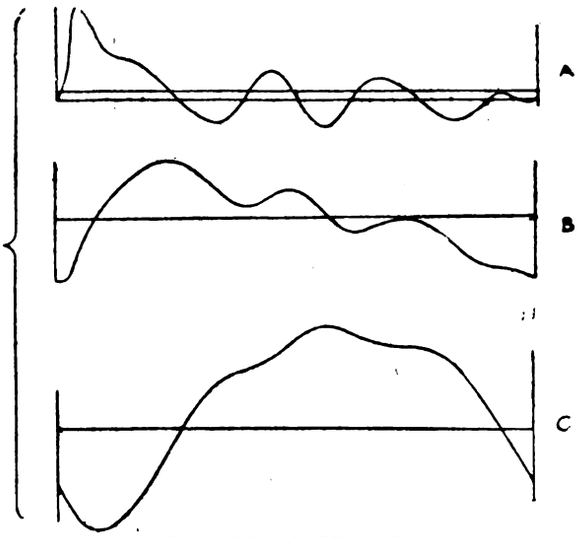

FIG. 1.—1-Cylinder 4-Stroke Cycle.

of this interaction, and are reproduced in Figs. 1 to 6. In each case three curves are drawn: (A) the turning moment curve corrected for inertia of reciprocating parts (the straight line representing the mean work or resistance is made with the same ordinate in all cases); (B) the corresponding angular velocity curve; (C) the corresponding

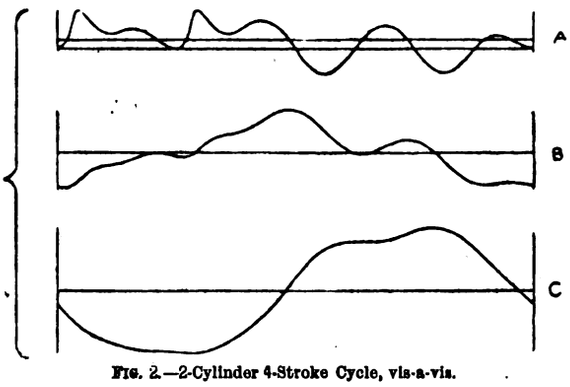

FIG. 2.—2-Cylinder 4-Stroke Cycle, vis-a-vis.

angular deviation curve, showing at any moment the angular difference between the position occupied by the flywheel and the position it would have occupied had the rotation been absolutely uniform. The moment of inertia of the rotating parts, the weight of the reciprocating masses per square inch of piston area, and the ratio of con-

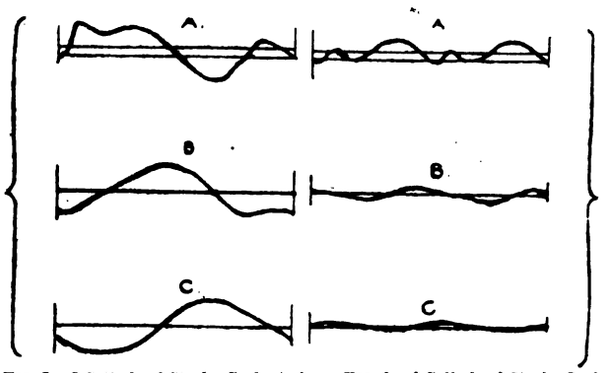

FIG. 3.—2-Cylinder 4-Stroke Cycle, twin. FIG. 4.—4-Cylinder 4-Stroke Cycle.

necting rod to crank length is assumed to be the same for all five cases. Using these diagrams it was found that for a 500-h.p. engine (700 h.p. maximum) running at 125 revolutions per minute, coupled to an alternator having a periodicity of 50 cycles per second, the ratio of the moments of inertia required to restrain the angular deviation to ±3deg. in all six cases was

One-cylinder four-stroke cycle				37·5
Two	,,	,,	*vis-a-vis*	23·1
Two	,,	,,	tandem	10·2
Four	,,	,,		1·0
One	,,	Oechelhauser		11·6
Two	,,	,,		1·0

These are theoretical results, and cannot be directly applied in practice; still they convey to the mind an approximate idea of the relative merits of the different types.

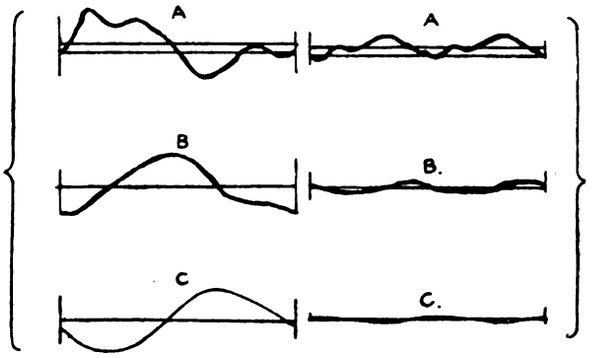

FIG. 5.—1-Cylinder Oechelhauser. G. 6.—2-Cylinder Oechelhauser.

The large central electric stations of the future will employ producer gas and gas-engines, and several existing stations with steam plant are to have gas-engines for additional power with the ultimate object of the entire replacement of all steam plant.

DISCUSSION.

The discussion was opened by **Prof. Kennedy,** who said that he had studied these questions from the point of view of money and economy and speed, and he would have done his utmost to use power-gas engines if they found that they were going to be the things that were wanted. There were a good many of them who had failed to convince themselves of that fact. He was very unprejudiced, because he had very nearly the earliest central station driven by gas-engines on a design of his own. But some further evidence was necessary as to the actual working economically and financially of those engines especially with power gas, not with blast-furnace gas, and this would be most interesting.

Mr. Crossley said they all owed Mr. Humphrey a debt of gratitude for what he was doing in connection with gas-engines. The *vis-a-vis* type was one of the most simple and the cheapest engine, and the most economical in working up to 20in. or 28in., but when they got beyond that they must go to a water piston, and then, of course, they could go to any size of cylinder. The watering of the piston was a considerable nuisance and danger. It was extraordinary how quickly a piston would heat if they withdrew the water, and it was terrible to think of the results. Then there was another reason, that once they had a piston rod cooled going through an explosive chamber they must lose very considerably. In gas-engines where gas cost them practically nothing, it did not matter, but if they had an engine of 28in. cylinder and a water piston, they would find that they lost about 9 per cent. due to this water piston rod. For moderate-size engines up to 28in. with pistons it was better to have the *vis-a-vis* type. With reference to the motion bars, up to a certain size he did not think they were needed, and they were a complication.

Mr. Michael Longridge said he knew very little about gas-engines. A short time ago he endeavoured to get tenders from English makers for 500-h.p. gas-engines, and he found there was hardly such a thing in the country. They had practically no experience of gas-engines in this country. A great many were at work in Germany, but those engines were mostly working with blast-furnace gas. He felt great diffidence in recommending anyone to go in for large gas-engines, although to his mind if they could be brought into a practical state they ought certainly to be the most economical and the best engines. He would be very glad to place an order with any of the agents of those engines either in Germany or in England.

Dr. Hopkinson said that Dr. Kennedy had doubted the value of the gas-engine in comparison with steam for central-station purposes. He would compare a full-load run upon a gas-engine and upon a steam-engine. They might take the comparative figures at something like 2½lb. of fuel per kilowatt-hour for the highest-class steam-engine, and taking into account the various losses in the case of the gas-engine it was something under 2lb. That difference might be made quite insignificant when other factors were taken into account in making up the total cost of energy derived from the two sources. But when they considered the conditions of an electric station where they had a load factor not exceeding 25 per cent., they would find that the comparison took a very different form indeed. He supposed from actual result that 8lb. of coal per kilowatt-hour was not a bad result for the steam-driven electric station. Although figures were not obtainable for gas-engines, still the stand-by losses were enormously less. If all these were fairly reckoned up, they would find that figures in the case of gas-engines which would compare fairly with the 3lb., in the case of the steam-engines would be about 8lb. That was an enormous economy, and he felt sure, if Dr. Kennedy would look at it from that point of view, he would find very ample justification for the view that the gas-engine must be the type of motor for the future in

Digitized by Google

the electric lighting station. He considered it purely from the point of view of fuel, and did not take into account the recovery of ammonia, which was remote, but it would greatly reduce the cost of energy.

Mr. Davey said he had listened to a good many gas-engine discussions, and he found that the gas producer was left out of the question generally. The gas-engine was of very little use without the producer. With the blast-furnace gases they had a producer which gave them the gas practically for nothing of fairly uniform quality, and without any difficulties that attended the use of ordinary gas-producers. What they wanted in the application of the gas-engine for general purposes, was a producer which would take the place of the steam-boiler. If they could get a satisfactory gas-producer, which could be worked at the same expense as the steam-boiler for stoking and so on, and they got 70 to 80 per cent. of the calorific value of the fuel. The gas-engine using such gas must be the most economical prime mover; and looking at it in that light, he was rather surprised that he did not find stations with gas-producers and gas-engines of a moderate size. If they had a satisfactory gas-producer of a moderate size, he believed it would lead to a general application of gas-engines.

Prof. Burstall said he had paid some attention to the question of gas-engines driving alternators in parallel. He had seen them, but he was bound to admit that in no case were they used in such a way as a central-station engineer would allow.

After a few words from **Dr. Hopkinson, Mr. Atkinson, Mr. Booth, Mr. Lawson,** and **General Webber,**

Mr. Humphrey replied. He said Mr. Crossley had mentioned the *vis-a-vis* type. It was doing excellent work, and it was only that he looked a long way ahead and saw a certain amount of standardisation when the gas-engine would entirely replace the steam-engine, and in that case they would have fewer types of engines, and probably the double-acting type would be the prevailing one. As to the cooling of the pistons in the case of the Nürnberg engine, they had got the piston carried on blocks, so that only the rings were pressing on the cylinder. Mr. Longridge must have made his enquiries some considerable time ago, because if he now enquired for a 500-h.p. engine there would be no difficulty in seeing plenty of them at work. He could show him six 500-h.p. engines together, and working day and night. There were differences between the two-stroke and the four-stroke cycle engine which would have to be carefully considered, and which did limit the speed, and this had a very important bearing on the question of cooling. A great deal had been said about the relative cost. They had steam-engines and gas-engines running in the same building, and looked after by the same superintendent, and they found that the cost, all included, for the steam-engine was about twice that of the gas-engine. He would be very glad to show them cases where gas was being made regularly and satisfactorily for use in gas-engines. He did not think there was any difficulty even if they wanted a small gas-producer of from 10 h.p. to 12 h.p. With regard to the cycle variation, he was prepared to admit that if they went to a maker and asked what cycle deviation in speed they wanted, he would say $\frac{1}{70}$th or $\frac{1}{30}$th. But that was not necessary, and one of the big American engineers assured him that $\frac{1}{100}$th was good enough for all purposes. Even if it was not, they were prepared to supply something better.

A hearty vote of thanks was given to the author.

ELECTRICAL ENGINEERING IN SOUTH WALES.

Electrical Motive Power in Mines and Collieries.

At the quarterly sessions of the South Wales and Monmouthshire Institute of Engineers, held at Cardiff under the presidency of Mr. Harry Riches, M.I.C.E., M.E., on Friday, July 10, the greater part of the time was occupied in the discussion of questions bearing upon electrical engineering. One of two papers submitted, and which caused a good deal of general interest, was that on "Electric Motive Power in Mines and Collieries," by Mr. W. A. Scott, A.M.I.E.E.

Mr. Scott, who has had wide experience as an electrical engineer, pointed out at the outset of his paper that electric power had been steadily growing in favour for mining operations during the past 10 years, and in the North of England and Scotland many very large plants had been installed for both pumping and haulage underground. It was, however, only during the past two years that any schemes of this description had been introduced into South Wales. Yet during this time some of the largest colliery electric power plants to be found in the country had been put to work, and were running most successfully in this district. No doubt many mistakes were made during the early history of colliery electric plants, and the writer ventured to say that many failures were due to the advice of incompetent persons, and also to that bugbear, the lowest tender, which had much to answer for here as well as in other branches of electrical engineering. There was no excuse now, however, for any mistakes being made, if only the experience gained elsewhere was made use of. But there was a tendency for contractors tendering on their own specifications to cut prices and put in an inferior job, which, unfortunately, was often accepted. The writer proceeded to outline the two chief types of electrical machinery suitable for power work—continuous-current and polyphase alternating-current machines—pointing out that up to the present time electric transmission work in this country had been carried out with the aid of continuous currents, and the majority of engineers were acquainted with the general appearance of this type, but for colliery work there were points of detail in design which were well worth considering, and these he proceeded to enlarge upon. The typical drum armature, the wires of which were embedded in slots cutting to the core, was now adopted in all first-class machines. Incidentally referring to the question of starting switches, Mr. Scott remarked that the type of starter to be used very much depended on the load the motor was to start. They had the choice of two types, liquid and metallic resistance, each of which had its advantages when used in the proper place. The writer's experience had led him to the conclusion that if the load to be started had great inertia, as heavy shears, large pumps, and such like, then the liquid screw-down switch was the best type to use. If the motor required to be reversed often, such as on cranes or main top rope haulage, then a liquid reversing switch had undoubted advantage in point of simplicity and minimum repair. An over-load and no-voltage arrangement could be combined with either of these switches, so that, from a point of safety, there was no difference between them and the metallic type, which were usually fitted with these arrangements. A metallic starter was very satisfactory for starting motors on fairly light loads; but a general mistake made with these was that the time taken to bring the motor up to full speed was quite neglected when ordering the switch. The result was that before the motor attained full speed, the resistances were red hot and the switch contacts burnt. This question of starter was really a very important one, and one which had not received the amount of attention which it deserved. It was not too much to say that the success or failure of a job greatly depended on the starter used. Speaking generally, whatever type of starter was used it should be of first-class mechanical construction, and the parts to be handled in its operation should be efficiently insulated. Metallic starters, when not encased in specified boxes, should on no account be mounted on inflammable supports, and main and switch boards should be supported on iron frames or brick pillars. Many serious fires had been caused by the neglect of these important points. Having expatiated at some length on the transmission line, he passed on to deal with the question of insulation of the cables. This required to be carefully gone into, and what would be suitable for one job might prove quite a failure in another. For mining work the writer's experience was that rubber cables were very unreliable, and paper-insulated cables covered with lead were not satisfactory. During many years' connection with this class of work he had found that cables insulated with bitumen stood better in damp places than any other. Mr. Scott afterwards briefly investigated alternating-current phenomena and machines in their principal features of application in power work, and went on to say that so far very little single-phase plant had been installed for power purposes, as it had presented considerable difficulty in regard to motors. There was, however, some likelihood of its early adoption in certain classes of work, such as railway electrification, although they need not look upon it as a great rival of the polyphase motor for some time to come. He was in favour of the revolving-magnet type, as the construction of the armature could be made a sounder mechanical job. The chief advantages presented by alternating-current machines were the absence of commutators and the ease with which high-pressure currents could be dealt with. If a stand-by exciting power was deemed necessary, Mr. Scott would advocate the electric lighting plant, which should be a direct-current set, built for the same pressure as the exciter, with sufficient margin of power and suitable arrangements for using it to excite the alternators. The polyphase type of motor best suited for mining purposes was the induction motor (or the asynchronous motor). Slot windings presented good features as regards winding and repairs; the coils could be formed before being laid into the slots, and by using mica ducts the mechanical protection was very good. The power factor of these machines was, however, lower, as the air-gap had to be longer. This was not altogether a disadvantage, as in colliery work a small air-gap was very liable to get choked. Some writers, and even some firms, advocated the squirrel-cage motor for all mining work, but the writer's experience was that for motors over 10 h.p. the slip-ring motor, with cased brush-gear, was a far more satisfactory job, and the additional risk introduced by the slip-ring was practically nil. He never recommended concentric cables for three-phase work, and advocated in connection with haulage work some suitable friction clutch on all gears, whether continuous current or polyphase, when the power became considerable. He was greatly in favour of starting large pumps through a by-pass, which he submitted had much to recommend it, and was a very inexpensive piece of work. Proceeding to consider the best type of generating plant suited to colliery work, he remarked that the type of engine which had found most favour with mining engineers was the horizontal slow-speed coupled compound, and there were many good reasons for this preference. First, the steam pressure in collieries was very often not higher than 80lb., but even if it was 100lb. to 120lb. the high-speed engine was not so economical as an automatic expansion-gear compound engine. Simplicity, as well as economy,

Digitized by Google

was one of the chief things to be aimed at. By providing an engine which the average colliery engineman could attend to and understand was generally of just as much importance as saving another pound of steam. In the case of large plants, say over 250 kw., or about 400 i.h.p., he would favour a direct-coupled set. It must be remembered, however, that direct-coupled sets for smaller power became very expensive in first cost compared on the basis of output, and unless due account was taken of the first cost when installing any scheme, the interest on capital invested would be a very high proportion of the cost of the units generated. It therefore seemed that for smaller powers of about 200 kw., although the efficiency of the rope-driven set might be a little lower than the slow-speed direct-coupled plant, it would be just as economical in cost per unit when the interest on the first cost was included in this figure. Many engineers advocated high-speed engines for colliery work, but he was of the opinion that, if space would allow, it would be better to put in slow-speed engines and rope-drive, even if their over-all efficiency was somewhat less (but this was not always so). The high-speed engine could only be economical at about its full load, as the valves had a fixed cut-off (which was set for the best results at full load), and at anything under this steam consumption per horse-power increased very much. Another point was that, when the bearings required taking up, a thoroughly skilled man was necessary, as the fittings of these must be accurate or trouble would be experienced. The writer knew of many installations running most satisfactorily with high-speed engines, but for heavy haulage in collieries, which was what they must prepare for now, they were certainly not to be recommended. However, if high-speed engines were adopted, then they must be fitted with forced lubrication to all parts, as by this means the wear and tear was reduced to a minimum. The best lubricating oil was the only thing to be employed in this case, otherwise the wear was very great. The question of lighting would usually crop up, and in most cases this should be done by a separate plant. It was often necessary to run the lighting plant week in and week out, and this could be best done by having a small set either belt driven or direct coupled. If the power plant was three-phase, the lighting should be at the same pressure as the exciters on the alternator shafts. Mr. Scott then gave a description of a large colliery installation—one of the largest in the country—erected under his supervision for the Tredegar Iron and Coal Company, at three of their pits in the Sirhowy Valley, Monmouthshire. This plant was for driving the whole of the haulage, both main and tail and endless ropes, also for pumping. Previously the greater part of this work was done by compressed air, and the remainder by steam, carried to the haulage gears at the pit bottom and some pumps in the shaft. As the output of the pits increased it became necessary either to increase the size of the compressing plant or to adopt some other means of power transmission. On the advice of Mr. Maurice Deacon, the consulting engineer to the company, it was decided to instal electricity, and the three-phase system was chosen as being most suitable for their mines. The object of introducing three-phase current was that commutators could be entirely done away with, and in cases where slip-rings were necessary these could be effectually enclosed in a gas-tight box. Dealing with the magnitude of two of the three collieries, he pointed out that high-tension circuits were in use for transmission of power to what was known as the Bedwellty pits, some mile and a quarter distance. The foundations for the haulage gear and underground pumps had been specially constructed to meet the requirements of the South Wales collieries, as regarded the movement in the floors and walls due to squeeze and heave. It had been often put to electrical engineers at what distance from the boilers did it become better practice to adopt an electric motor in place of a steam-engine? This question had given rise to very many opposing views, but to the writer it did not seem a difficult matter to decide. In the first place, it was obvious that the cost of power would be greater per horse-power at the dynamo terminals than at the engine crankshaft, and if they could use a steam-engine of the same class and efficiency as they used for driving the dynamo, and the distance from the boiler did not cause great condensation in the steam-pipes, then it would not pay to put in a motor, which would require a dynamo to drive it, or, in other words, to add two links in their chain. Therefore, if the power required was about 100 h.p. or over, the factors which would decide whether an engine or a motor should be used would be the length of the steam-pipes and the class of load. If the load was intermittent, then the losses from condensation in the pipes bore a greater proportion to the horse-power developed than when the load was regular, and for this reason alone it was often advisable to put in a motor, which consumed no power when it was not running. The case of small engines was quite another matter. The average steam consumption of the best of them was not less than 60lb. to 70lb. of steam per indicated horse-power, and in most cases it was twice or even three times this amount. If these engines were scattered around the surface (the distance from the boilers need not be very great), the losses in condensation would be nearly as much as would keep the lot running at full load. To quote a case in point, the writer was asked to prepare a scheme for electric driving in a steelworks, and for this purpose he took some tests of the losses in condensation on nine small auxiliary engines, averaging about 10 h.p. each. The steam condensed in the pipes leading to these engines was measured, and found to be 3,604 gallons in 12 hours, and the coal used was 2¼ tons, which gave an evaporation of 8lb. of water per pound of coal. As the boilers were steaming easy, it was safe to say that in ordinary working the average evaporation was not more than 6lb. of steam per pound of coal, which was unwashed small. This meant that the coal used under ordinary conditions of working would be about 2 tons 14cwt. in 12 hours for condensation in pipes to these engines. One only need work this out for the year to see how much was likely to be saved by adopting electricity in such a case. Transmission of power by shafting was, in most cases, a very wasteful method, and they lost, maybe, anything from 15 to 77 per cent. The average was, perhaps, about 40 per cent. In one case in the writer's knowledge 15 h.p. was transmitted to a distance of 263ft. Two shafts, a reducing gear, and four belts were used, and from tests taken it was found that 8 h.p. was absorbed by shafting and belts. Of course, a motor in this case would soon pay for itself. Instances of this sort might be quoted by the dozen, but the writer believed that the economical advantages of electricity were fully realised by mining engineers generally. One other item might be mentioned, and that was the approximate cost of generating electric power. One saw some wonderful figures sometimes given as the cost of generation in some certain cases, but whether these included all the items which should be included it was difficult to say. In one or two installations with which the writer had been connected the costs had been carefully noted, and the units generated were registered by means of wattmeters, which, by the way, should be part of every installation. At a large steelworks in that district the power was generated by two high-speed direct-coupled engines and dynamos, each set being about 350 i.h.p., and one set was large enough to deal with the whole of the load, the other being kept as a stand-by. The average annual consumption was about 300,000 units, and the cost per Board of Trade unit, including coal, oil, waste, and stores, two stokers, two drivers, three arc lamps and motor attendants, one chief electrician, all arc lamp carbons and motor brushes, renewals of incandescent lamps, and all sundry materials connected with the actual use of electricity, for the past 18 months, had worked out at 1·01d. per Board of Trade unit. The cost of power at Pochin Pits, Tredegar, had been estimated at ·43d. per Board of Trade unit for an annual consumption of about 300,000 units per annum; this cost included all stokers', drivers', and electricians' time, and proportion of the chief mechanic's time for supervision. Another instance was Messrs. Dorman and Long steelworks, Middlesbrough, with which installation the writer was connected for some considerable time. Here the annual consumption was something like 2,000,000 units, and the cost per unit was ·224d. Cheap power, however, was not the only advantage of electricity; there were many others, such as higher output from machine tools when used in workshops, less wear and tear, and ease with which portable tools could be adopted. These and many other incidental advantages accrued from the use of electric power, and the writer ventured to think that before long even larger colliery installations than Tredegar would be seen in South Wales. During the past two years great activity had been displayed in England in the formation of large electric power companies dealing with extensive tracts of country, and covering, under their parliamentary powers, vast areas for the supply of electricity in bulk. In certain cases and under favourable conditions with regard to the district to be supplied the companies might meet with success, but this would greatly depend on the price at which they were prepared to supply power to the fairly large consumer. The cost at which these companies could supply would be largely dependent on the nature of the district, whether scattered or not, as it must be remembered electricity was not transmitted without loss, and the greater the distance between consumers the higher the price must be to make it profitable. For small works and factories requiring about 100 h.p. to 150 h.p., it would, no doubt, be found that power from a company at 1d. per unit would be more profitable than putting in a plant and generating it in the works. In cases such as these the companies should have a good field before them. The writer did not think, however, that a company could generate and supply large collieries, requiring, say, 300 h.p., cheaper than the collieries could generate it themselves. In conclusion, Mr. Scott said that it was only by discussion that they could arrive at some general standard for colliery work, and there seemed to be great room for something of the kind, and added that in the non-condensing station it was noticeable, in cases which he cited, that the generating sets were only half the size of those in the condensing station. All the engines were of the high-speed type, and these were in every way satisfactory under the severe conditions of continuous heavy loads. After five years' running the cylinder liners showed practically no wear. The individual

Digitized by Google

motor system had been tried largely in America, but he was inclined to think that a combination of the two systems was likely to prove best in the long run—*i.e.*, to run all large tools, such as heavy planers, boring mills, and lathes by individual motors, and all the smaller tools in groups of five to eight, from a length of shafting, for which a 10-h.p. motor would usually be ample.

The discussion on the paper was adjourned to the next meeting.

Electricity as "The Motive Power of the Future."

An animated discussion took place on the views propounded by Mr. HORACE D. B. HOW, A.M.I.E.E., on "The Motive Power of the Future," which Mr. How declared would be "electricity."

Prof. A. C. ELLIOTT, D.Sc. (South Wales and Monmouthshire University College), recalled the fact that when it fell to his happy lot, 10 or 12 years ago, to devise an engineering laboratory at Cardiff he immediately resolved upon electrical driving—the first venture of the kind in the locality, though it was on a very small scale comparatively, and that for a satisfactory reason. But it did not satisfy him, for he was anxious for yet more substantial outcome, and he was now confident of realisation, for the antiquated things of the past had been superseded, and they had automatic tools that could be run up to their proper speed and kept at it for hours. He insisted on the importance of having sufficient regulation. He referred to tests of bare and armoured electric cables as bearing upon their safe adoption in fiery mines, and jocularly observed that it would seem that the word "armoured" exercised in these connections much the same distracting effect upon some minds as the word "Mesopotamia" did upon the famous old lady in the story.

Mr. STEWART (Abertillery) felt anxious to know what sort of engine Mr. How regarded as the one likely to be adopted in the future. They had heard a good deal of the remarkable engine that was about to be put down for the Metropolitan Company in connection with what was expected to be one of the largest installations in the country, and he had himself to do with an installation in which the engineer advised them also to put down an engine of the same class.

Mr. R. FORDAN (Newport, Mon.) did not conceive anyone would care to take a cable in the face of workings where the mine was considered dusty and fiery. But, on the other hand, he saw no objection to taking a cable to a colliery where one could without risk work with a safety lamp. He advised, with regard to the electric cabling of good haulage roads, that the fixings should be out of the way of trams, and, subject to such precautionary provision, he saw no more danger in carrying electricity over the main roads than in carrying ordinary colliery lamps. As to the use of high-speed engines, that was one of the most interesting issues in connection with the introduction of electricity underground. Colliery managers had no doubt been much in favour of slow-speed engines so far, but that was somewhat excusable, bearing in mind that they had been accustomed to them so many years; and again, it must not be forgotten that the mechanics at the coal-pits were not always as experienced as the men engaged on the staff of an engineering works. The great feat of engineering was not to repair an engine after it had broken down—anyone of them could do that—but to maintain the engine in fit and repaired condition as to obviate the harsher experience. High-speed engines would be difficult for the average man to understand for a little while, and that was where prejudice came in. But the difficulty would be in due time surmounted. He, personally, favoured the high-speed engines, for they could be utilised in a very small space, and there were other considerable advantages.

Mr. HOWE replied to the criticism at some length. He believed that some years hence their engineers would all, to a large extent, be electricians—the next generation of engineers would have to be "electrical" men, and he had compiled his paper in view of this fact, and because he thought that many of their engineers knew nothing at all about the subject. He had no hesitation in attributing the prejudice to high-speed engines at collieries to ignorance of them. But this was no "fault" of the engine itself. They had high-speed engines running all over the kingdom, and where collieries had not got proper men to look after them, why, for heaven's sake, get them. Efficiency was what they wanted. He strongly advocated turbines for collieries. As an electrical engineer, he would put down an armoured cable, polyphase machinery, and include switchgear to do any duty required in the most fiery mine in South Wales. Colliery engineers might not be so bold, but he was prepared to do what he said and work the thing for six months, and stay down himself, so confident was he in the feasibility of the proposal to apply electricity in mines. The fear of electricity arose from lack of knowledge of it. If colliery managers would say what they wanted, electrical engineers would do what was required. There was no problem in colliery work that he would be afraid to tackle, and he said this after having devoted a great deal of thought to the subject. There were heaps of places in South Wales where the application of electricity would mean saving the cost of the plant in about three years, and if the system was gradually applied at a works, he was confident that the whole of the pits would be equipped in five years. The maintenance cost was not high, and he summed up the contrastive advantages of electricity as a motive power as fourfold—viz.: in the transmission, high efficiency, reduced cost of attendance, and reduced wear and tear of machinery. Mr. Hugh Bramwell had pointed out that at several collieries in Westphalia winding engines were doing heavy work from depths up to 1,000 yards very successfully with electrical power, and had said also that he thought collieries in the future would be entirely equipped electrically. He (Mr. Howe) agreed with Mr. Bramwell, and predicted that in five years the present kind of winding engines would pretty well have died out in South Wales.

Other contributions were made to the discussion on the paper, Principal GRIFFITHS, of the South Wales College, having already expressed the belief that it was not beyond the resources of science to make arrangements by which the breaking of a cable would not yield a spark.

A vote of thanks was accorded to Mr. How for his paper, and the debate, it was understood, again stood adjourned. The other subjects dealt with were outside the scope of electrical reference.

CHESTER ELECTRICITY ACCOUNTS.

The total expenditure on capital account of the Chester Corporation electricity undertaking on March 25 last amounted to £105,924. Below we give abstracts of the accounts for the past year.

Dr. REVENUE ACCOUNT.	£	s.	d.
Coal or other fuel	1,637	5	9
Oil, engine-room stores, etc.	366	6	11
Wages at generating stations	1,097	14	9
Repairs and maintenance of generating plant, etc.	496	1	1

NOTES.

Correspondence Instruction.—Elsewhere in this issue is a notice that instruction by letter in mechanical and electrical engineering can be obtained from Prof. Jamieson, Kelvinside. This class of instruction is of great value to those students, whether in the electrical or mechanical branches of the profession, who by reason of their employment are isolated from the usual means of instruction—such as the various classes held in the large owns in the United Kingdom.

The Motorcar Bill.—This Bill, which has now become law and will come into force the 1st of next year, can be viewed from two standpoints. The owners of motorcars look upon it as a failure in spite of the fact that the higher speed of 20 miles an hour is legalised on country roads. This higher speed, however, is accompanied with other restrictions which are irksome to the expert motorist. From the public point of view we think the Bill moves in the right direction, in that it will prevent undue harassing of motorcar owners by magistrates who lack judgment and are biassed. This Act also makes drivers responsible for any recklessness irrespective of the actual speed at which the car is going. In our opinion the Automobile Club has done more to prevent reckless driving than the new Act, and its plan of expelling from membership any who have been proved to drive at excessive speeds will have an excellent effect.

Wireless Telegraphy Conference.—This international conference, held at Berlin, has now concluded its labours, and it has received the thanks of the Imperial Secretary of State for the German Post Office, speaking for the Emperor. The results of the conference have been embodied in draft regulations for the control of wireless telegraphy, which will now be submitted to the various Governments represented at the conference. The conclusions of these regulations are to be treated as confidential, but it is asserted that they advocate the Government control of wireless telegraphy in all countries. The members attending the conference had every facility offered them by the German companies for seeing the German systems of wireless telegraphy. Another interesting experiment was one by Mr. Schmidt, who showed an instrument that enabled a station using one system to be attuned to the stations of any other system, so as to secure interchange of signals. In other words, he showed that he could interfere with the secrecy of any system now in commercial use. The final solution of the international question of wireless telegraphy has yet to be arrived at.

Electric Railways.—Colonel Mellor, speaking as chairman at the recent half-yearly meeting of the Metropolitan Railway Company, gave some interesting figures as to the advantages which that railway and its patrons would derive from the conversion of the system to electrical working. He spoke on the assumption that the line would carry some 50 million passengers per annum, and that each passenger would use the train for two journeys of 12 minutes per day. It then follows that by the reduction of the time required to run round the circle from 70 minutes, as at present, to 50 minutes by electric traction, the railway would save its passengers no less than the equivalent of 300,000 working days of 10 hours each per annum. The time so economised is valued at 3s. 4d. per day, and makes a saving of £50,000 to the travelling public. Quite apart from this, the increased speed would add 30 per cent. to the capacity of the line, of the rolling-stock, and of the permanent way. The chairman's estimates seem to us well within the mark, and we trust that the time will soon arrive when it can no longer be said that only those who must patronise the tunnels of the Metropolitan Railway Company.

New Annunciator System.—A new annunciator system has been designed by Mr. R. Dachsel, with the idea of reducing the number of circuits required, and which is described in the *Elektrotechnischer Anzeiger*. With the ordinary system each button requires one independent wire, though many may be grouped together on a common return. In the new arrangement two or more return circuits are used. The buttons are then grouped so that those having the same return circuit are connected to separate outgoing circuits, and those on the same outgoing circuits are connected to separate return circuits. Thus, supposing there are four buttons, four lines are required, two outgoing and two return. There is an annunciator drop in each circuit. Those on the outgoing circuits show numbers, those on the return showing colours. Thus, if button No. 1 is pressed, a drop falls showing two numbers, 1 and 2, on different coloured backgrounds. A second drop opens showing one colour, indicating that that number having the same coloured background as the second drop is the number of the button which has been pushed. The system here outlined is the simplest form, as a combination of three or more numbers to a drop, or three or more colours, enables a further saving of wire to be made.

Radium and Cancer.—Dr. Alexander Graham Bell has in a letter to Dr. Sowers, a physician of Washington, made a suggestion which may lead to good results. He said in the letter: "I understand from you that the Röntgen X-rays, and the rays emitted by radium, have been found to have a marked curative effect upon external cancers, but that the effects upon deep-seated cancers have not thus far proved satisfactory. It has occurred to me that one reason for the unsatisfactory nature of these latter experiments arises from the fact that the rays have been applied externally, thus having to pass through healthy tissues of various depths in order to reach the cancerous matter. The Crookes tube from which the Röntgen rays are emitted is, of course, too bulky to be admitted into the middle of a mass of cancer, but there is no reason why a tiny fragment of radium sealed up in a fine glass tube should not be inserted into the very heart of the cancer, thus acting directly upon the diseased material. Would it not be worth while making experiments along this line?" To this letter Dr. Sowers replied: "The suggestion which you make in regard to the application of the radium rays to the substance of deep-seated cancer I regard as very valuable. If such experiments should be made I have no doubt they would prove successful in many cases where we now have failures."

Motorcar Reliability Trial.—The fifth annual motorcar trials organised by the Automobile Club are to be held this year from Sept. 18 to 26, inclusive. The trials will be of reliability and not speed. Elaborate rules have been drawn up, whereby over 130 cars, each of which will be under the continuous observation of an official club observer, will cover 1,019 miles at slow touring speed. It will be the observer's duty to note every stoppage for repairs or adjustments, and even for filling the petrol tanks, so that an absolutely reliable report will be obtained as to the performance of the cars over that distance. Such a test should go far to prove to the public that designs which have been suggested and proved by recent races have been put into practical shape for ordinary touring purposes. In addition to considering ordinary reliability, a number of other points are to be taken note of in making the awards for these trials. Probably the one which will be the most appreciated by the British public is the award of marks for

Digitized by Google

absence of dust raising. There is no doubt that this is one of the most serious objections, from the public point of view, to the more general use of cars, and the effect of these trials will be to draw the attention of the makers to this important question. The routes of the trials will extend from the Crystal Palace to various seaside places and back on the same day, so that a large number of people will have an opportunity of witnessing the performance of the cars during the trials. The places to be visited include Margate, Folkestone, Eastbourne, Bexhill, Brighton, Worthing, Southsea, and Winchester.

Radium.—Sir Oliver Lodge, writing to the *Times* under the date of Aug. 14, points out that "all the known properties of radium are consistent with the hypothesis that a rearrangement of parts is going on inside the atom, and that it is not a case of chemical action in the ordinary sense at all. There is no difficulty in accounting for the energy in this way." Incidentally, he mentions that he is struck with the dependence of the populace on "the daily Press for their scientific interest and information. In France it appears that many educated and professional persons have barely heard of the existence of radium, and the name of Mme. Curie means nothing to them. They are, indeed, in the position of English people in 1888-95 with respect to the discoveries of Hertz and his successors, a subject which the Press did not happen to take up until it was popularised by an application to telegraphy. In the equally important matter of radium, however, the British public have had their interest stimulated and have been kept well informed—largely through the agency of the *Times*." We quite agree with him in this last respect, that you cannot get a non-technical public to read the technical Press, but they will absorb a certain amount of scientific knowledge if it is mixed in with other information. Unfortunately, unlike the *Times*, some of our daily papers cannot be said to give scientific information in their columns. We mean that their science notes are too frequently incorrect and too often directly contributed by unscientific inventors, who have as little real knowledge on the subject on which they write as the editors who accept the copy.

Electro-chemical Industries.—A review of the progress made in electro-chemistry and electro-metallurgy will soon convince anyone that electricity is revolutionising certain of the chemical industries. It is to Niagara that one must look for the most advanced improvements in this direction, as the cheap power that can be obtained there is also accompanied with other local advantages such as are not enjoyed by those power undertakings in less highly-developed countries. Amongst the successes at Niagara is the manufacture of carborundum, which is displacing to a large extent other abrasive material. This is especially so in connection with the steel trade, and it is said that the steel industry alone takes 75 tons of carborundum per month. Aluminium is now manufactured wholly in electric furnaces, but the spread of the aluminium industry is not quite so fast as had been hoped. Its position as a successful competitor of copper has been threatened by the fall in the price of that metal. Another commercial undertaking at Niagara is the manufacture of phosphorus in an electrical furnace from phosphate mixtures. Artificial graphite, produced electrically, is a product which has now reached the commercial stage, and this graphite is now being manufactured in very large quantities. The return for 1901 showed a production of almost 1,000 tons, and the increase since then has been marked. In the electrolytic production of caustic alkalies and chlorine, the new industries have to face a widespread monopoly, but even here the electrical undertakings have reached commercial stages, although they produce but a very small percentage of the large total of these materials required. Other processes now in course of development promise wide fields for the use of cheap electrical energy, and also that electrical industries will in time replace the many more roundabout chemical processes used up to the present.

The British Association.—More information is now to hand as to the programme of the forthcoming meeting at Southport. The first general meeting will be held on Wednesday, Sept. 9, at 8.30 p.m. precisely, when Sir Norman Lockyer, K.C.B., F.R.S., president-elect, will assume the presidency, in succession to Prof. James Dewar, M.A., LL.D., D.Sc., F.R.S., and deliver an address. On Thursday evening, Sept. 10, at 8.30 p.m., there will be a *soirée*. On Friday evening, Sept. 11, at 8.30 p.m., a discourse on "Man as Artist and Sportsman in the Palæolithic Period" will be delivered by Robert Munro, M.A., M.D., LL.D., F.R.S.E. On Monday evening, Sept. 14, at 8.30 p.m., a discourse on "The Old Chalk Sea, and some of its Teachings" will be delivered by Dr. Arthur Rowe, F.G.S. On Tuesday evening, Sept. 15, at 8.30 p.m., there will be a *soirée*. On Wednesday, Sept. 16, the concluding general meeting will be held at 2.30 p.m. A good programme of excursions has been arranged, and these will, if the weather is propitious, be much enjoyed by those present. This year the presidents of the various sections are as follows: for Section A, which deals with mathematics and general science, Mr. Charles Vernon Boys, F.R.S.; Section B, dealing with chemistry, Prof. Walter Noel Hartley, D.Sc., F.R.S.L. and E.; Section C, on geology, Prof. William W. Watts, M.A.; Section D, on zoology, Prof. Sydney J. Hickson, M.A., D.Sc., F.R.S.; Section E, which takes geography, Captain Ettrick W. Creak, C.B., R.N., F.R.S.; Section F, dealing with economic science and statistics, Mr. Edward W. Brarrook, C.B.; Section G, on engineering, Mr. Charles Hawkesley, M.I.C.E.; Section H, on anthropology, Prof. Johnson Symington, M.D., F.R.S., F.R.S.E.; Section K, which has botany for its subject, Mr. Albert Charles Seward, M.A., F.R.S.; and Section L, dealing with educational science, Sir William de W. Abney, K.C.B., D.C.L., F.R.S.

The Paris Disaster.—The lamentable disaster on the Paris Metropolitan Railway, to which we referred in our last issue, may or may not be looked upon as due to electricity, according to the care which is taken to examine the information at hand. We notice that the engineer of the line took the same view of the matter that we did—*i.e.*, that the disaster was caused by the officials who ordered the burning train to be pushed forward along the line into a tunnel, instead of shunting it on to sidings in the open air provided for the very purpose of housing disabled trains. To the editor of the *Lancet* the other point commends itself. He is always great on short-circuits, and in the present instance writes on "the fearful results that might arise through a diversion of the electric potentials on electric railways." The editor is so far wide of the truth that he concludes, "There is little doubt, therefore, that the defective motor was the cause of a disastrous short-circuit, with the result that the train and the succeeding trains caught fire in the tunnel." The evidence is clear that the train was on fire before it entered the tunnel, and that the loss of life was due practically to the spreading of the fire along the train by its motion through the air. As we wrote after the Liverpool affair we would again write: that electric traction is, *per se*, more safe than any older means of locomotion. It seems likely that there may be considerable friction between the municipal authorities of the city of Paris and the Metropolitan Company over the recent disaster. In the first instance,

Digitized by Google

the tunnels were constructed by the city, we believe, to the designs prepared by the advisers of the city, and the Metropolitan Company was only responsible for the electrical installation and for the capital charges incurred by the municipality. The question, then, as to whether the tunnels are properly constructed with sufficient air ventilation and air shafts, is one which lends itself to litigation between the two parties as to which is mainly responsible for the recent regrettable loss of life.

Radium Researches.—Investigations on the behaviour of the emanations from radium are being carried on by a large number of expert scientists. The advantage of the independent investigations thus being carried out, together with the mutual discussion of the results obtained, should do much to clear up the mysteries of these emanations and the peculiar properties of radium. A *brochure* just issued from the *Proceedings* of the Royal Society contains four important papers on this subject. Amongst the contributors of these papers are Lady Huggins, Miss Willcox (of Newnham College), Sir William Ramsay, and Mr. Soddy. The first named, in conjunction with her husband, Sir William Huggins, endeavoured to obtain the spectrum of the spontaneous and luminous radiation from radium at ordinary temperatures. A preliminary prismatic examination of the glow from pure radium bromide was made by eye, when a very faint spectrum was noticed. Photography was then invoked in order to obtain, if possible, a record of the blue, violet, and ultra-violet regions of the spectrum. Ultimately, with an exposure of 72 hours, a negative was obtained, consisting of eight bright lines and at least eight faint lines, together with a misty trace of continuous spectrum in the blue region. The final result, so the authors say, has shown, quite unexpectedly, that the seven strongest lines in the new spectrum agree not only in position, but also in relative intensity and character, with bands of the spectrum of nitrogen, and, further, that nearly the whole of the ultra-violet radiations appear to come from nitrogen. Additional photographs are, however, to be taken with a longer exposure, when "it may be that indications of helium, and possibly of radium itself, may be forthcoming." The last two named experimenters investigated the connection between the radium emanations and helium. They affirm that from spectrum analyses the helium always accompanies the radium emanations. The characteristic lines have been observed, identical in position with those of a helium tube thrown into the field of vision at the same time. Sir William and his co-experimenters extract the emanations by the aid of a special pump, and deal with it as they would a gas, condense it in a U-shaped tube, surrounded by liquid air—a cold of about 190deg. C.—and even "wash" it with another gas, while the passage of emanation from place to place through glass tubes can be followed by the eye in a darkened room. The communications which are supplementary to these papers include one by Mr. W. B. Hardy and Miss Willcock, referring to the influence of the rays from radium upon chemical change, and other actions. Tubes containing a solution of iodoform in chlorophyll were enclosed in a box of black cardboard, and they remained unchanged for 60 hours. On placing the box over radium bromide the tubes became purple in about 10 minutes. Further instances of chemical decomposition are given. Lastly, there is a paper by the Hon. R. J. Strutt, a son of Lord Rayleigh, on the most penetrating rays of radium. Altogether, some notable advances are indicated by these authors in their respective departments.

Variable Speed Control.—Mr. Wm. Cooper read a valuable paper before the recent Chicago convention of the National Electric Light Association, in which he compared the relative advantages of electrical and mechanical methods of variable speed control for general power purposes. The conclusion he arrives at are instructive, and in the following we abstract some of the most important. In the first place, in the installation of a new manufacturing plant in which machinery will be used that will require to be used at varying speeds, the methods employed should be considered in about the following order: first, what system will assist in yielding a maximum output from the machinery installed; second, the comparative costs of the different methods installed. Usually, in the consideration of the advisability of installing any certain method of operation, the questions are put in the reverse order to that given above, the question of cost being wrongly placed before that of output. Great care should be exercised in the selection of motors for different machines to determine whether the horse-power required is practically constant or varies with the speed. In most machines of a reciprocating action—slotters, shapers, planers, etc.—the power required varies with the speed, as the power is consumed in the reversals of the machines, and not in the actual work being done. In cases of this kind, the motor will be called upon to do its maximum work at the maximum speed of the machine, while in the case of machines in which the work performed is constant, irrespective of the actual speed of the machine itself, the power required to drive it will be practically constant throughout the entire range of variation. In machine-shop tools, such as lathes, boring mills, milling machines, etc., this condition exists. When the range of different voltages impressed upon the armature of the motor, and the range through which its speed is changed by changing the amount of magnetism in its field, are properly apportioned, the minimum sized motor for a given total speed variation is obtained. To get the minimum speed we must use some other method than field control, because the field is already up to its maximum strength, and we therefore introduce a lower voltage. The ratio that this lower voltage bears to the normal voltage is the same as that which the lower speed bears to the normal speed. By the combination of multi-voltage and field control we are able to use the minimum size of motor for the given work. In conclusion, the author presents the following few simple rules for use in determining the relative size of motors for constant horse-power application: (1) the total range of speed, using both variable voltage and field regulation, will be as the square of the range of voltages; (2) the change in horse-power will be directly proportional to change of voltage impressed on the armature, the field being constant; (3) the change in horse-power by change of field strength will be inversely proportional to the change in speed, the voltage on the armature remaining constant; (4) the relative size of the motor, as referred to the maximum speed, will be directly proportioual to its speed variation, when using variable voltages; (5) the relative size of the motor, as referred to the maximum speed, will be as the square of the speed variation when using field regulation.

Electric Batteries with One and Two Electrolytes.—In a paper on the above subject recently read before the French Academy of Sciences, Berthelot discusses the general relations existing between the E.M.F.'s of the various elements with equal or different electrodes and electrolytes. These relations may either be of a general character, being a consequence of the general laws of electricity, or else constitute special laws established on more or less sure hypotheses, and requiring confirmation

Digitized by Google

by experiment. The results recorded in the present paper are relative to measurements made after the equilibrium corresponding to normal initial conditions was established—*i.e.*, before any noticeable disturbing phenomena due either to polarisation, or to an alteration of the metals; or, finally, to a progressive mixture of the electrolytes through the partition wall of porous vessels had occurred. The author first discusses elements made up of a single electrolyte, two different electrodes and two wires of the metal of one of the electrodes. Berthelot confirms for the case of several elements, the electrodes of which (M, M′, M″) consisted of zinc, copper, and platinum respectively, and where the electrolyte was a solution of the different salts, acids, or mixtures of both, the relation

$$E_1 + E_2 = E_3,$$

as derived from the equations

$$E_1 = M \mid A + A \mid M' + M' \mid M,$$
$$E_2 = M' \mid A + A \mid M'' + M'' \mid M',$$
$$E_3 = M \mid A + A \mid M'' + M'' \mid M.$$

This formula, deduced in virtue of Volta's law, is confirmed in the case of the following substances: H_2SO_4, KCl, H_3BO_3, $ZnCl_2$, $2KCl + Na_2A_4S_2$, $2NaCl + K_2SO_4$, $2NaCl + ZnSO_4$. As regards elements with two electrolytes A and B, there may be formed nine different elements from three different electrodes, three having equal and six different electrodes. Now it may be seen that

$$\text{E.M.F. (M A B M')} + \text{E.M.F. (M' A B M)} =$$
$$= \text{E.M.F. (M A B M)} + \text{E.M.F. (M' A B M')},$$

corresponding additional relations being deduced in a similar way. The whole of Berthelot's experiments shows these laws to be true.

Hull Telephones.—It will be remembered that the fight between the Corporation and the National Telephone Company at Hull, has by no means been confined to the ordinary scope of competition. The Corporation had an agreement with the company with regard to wayleaves which they could terminate, and this has placed them in a better position when arranging for intercommunication between the Corporation exchange and the National system. As a result of lawsuits and lengthened negotiations the following agreement has been accepted by both parties—*i.e.*, "That in consideration of the National Telephone Company withdrawing their appeal and agreeing to mutual free intercommunication between their subscribers in the Hull area and those who may join the Corporation system, and also mutual intercommunication between the latter and the subscribers of the company in other towns through the trunk wires of the Postmaster-General without any terminal or other charges being made by either the company or the Corporation, the Corporation shall continue present and future underground wayleaves to the company until the expiration of the company's licence in 1911, on the terms of the agreement of March 18, 1899, except that the payments under such agreement shall be reduced by one-half as from March 18 next, the cost of the necessary junction lines to be borne equally by the company and the Corporation." We are of opinion that as the result of our discussion with the representatives of the company that, in the event of the Corporation not entering into competition at present, an alternative proposal could be effected on the following basis: (1) The company to forthwith introduce (in addition to the existing party lines and other services) a measured service tariff on the following scale: £5 to cover 600 calls per annum; £6, 1,000; £7, 1,600; £8, 2,100; £9, 2,600, all inward calls to be free, and excess local calls to be charged for at the rate of 1d. per call. (2) The unlimited rates to remain as at present; and (3) the company to pay for the underground wayleaves the full charges mentioned in the agreement of March 18, 1899. In spite of this agreement, we believe there is to be considerable opposition at the forthcoming enquiry over the municipal loan for telephone purposes.

Atmospheric Electricity.—In a recent report of the United States Weather Bureau some interesting experiments are described which had for their object the determination of the normal distribution of electrification in the atmosphere. The investigators have used, like Franklin, a special kite as a means of determining the electrification of different strata in air. The cord which held the kite was wound spirally with a fine copper wire attached to an electrometer, so that, by the usual optical methods, accurate readings of the electric intensity at any height could be obtained. The most notable results recorded are that the higher regions of the atmosphere—viz., from 7,600ft. to 12,300ft. above sea-level—are always in an electrified condition, and that the electric intensity is very greatly increased during showers or thunderstorms. In perfectly calm weather the needle of the instrument moved forward or backward as the kite rose or fell in the air, showing that the electric intensity varied with the altitude. A detailed account of the electrical state of the atmosphere during a storm is given. Under such conditions a torrent of sparks could be drawn from the conducting wire, but the current was not enough to light up an incandescent lamp of 105 volts. In other experiments the water-dropping collector was used, especially in investigating the distribution during a thunderstorm. Here, at one moment, the electrometer would show that the atmosphere had a strong positive electrification; this would increase until a flash of lightning occurred, when the needle would oscillate violently, finally showing a strongly negative condition. The intensity of electrification at any one point during a storm depends upon its distance from the storm area. The constant existence of some electrical condition in the atmosphere lends interest to enquiries as to the extent of the earth's electric field. Investigations at the highest altitudes it is at present possible to reach seem to show that the upper limit is in the area between 10,000ft. and 15,000ft. above sea-level. Above this area the electric potential may be regarded as constant. The cause of this phenomenon has not yet been satisfactorily elucidated, and various theories have been brought forward to account for it. These all agree in regarding friction between particles of the same or different materials, such as water and air or water and ice, as the initial cause. These researches seem to indicate that the impact of rain on the surface of a lake or sea, or even the wind blowing on these surfaces, produce electricity, which may be the initial cause of thunderstorms.

Three-Phase Transmission Systems.—The recent paper read by Mr. Blackwell before the Niagara Convention of the American Institution of Electrical Engineers had for its subject the consideration of various systems of multiphase transmission mains and the question of earthing various portions of the same. In the course of the discussion, Mr. Peck showed that the added responsibility of earthing is mainly concerned with the voltage distortions which result from the short-circuiting of transformers by grounding or otherwise. The effect of the distortion thus superinduced may be great enough to more than double the voltage across certain of the lines under certain conditions and with certain connections. To catalogue the conditions and their effects would be to cite bodily Mr. Peck's tables, to which reference should be made for particulars.

Digitized by Google

Some things, however, are worth noting. Either pure star, grounded generator and all, or pure mesh connections are safe enough from abnormal voltages. Of the mixed systems in common use, most are somewhat liable to the chance of getting abnormally high voltages on some part of the circuit, of which the chance of a short-circuit on a raising transformer is the most likely cause. With one branch of a raising mesh out there is a beautiful chance for trouble ahead. The moral is that the high-voltage transformers must be kept out of mischief by particular care. In ordinary practical operation the crippling of a raising or reducing transformer puts the circuit so thoroughly out of business that the distribution of voltages becomes a matter of secondary importance anyhow. Any system of operation which saves copper is liable to serious derangement of the voltages in its respective parts, and in using such a system, whether the common three-wire or some strange and complex polyphase system, it ought to be distinctly understood that one has to pay a reasonable price in care for the saving in cost of conductors. In the early days of the three phase system it was a constant source of joy to the unregenerate to see the continuous-current contingent, whose daily food was balancing and boosting, howling about the dreadful result of unbalanced load on a three-phase system. It is doubtless true that with the feeder drop common in direct-current practice, a three-phase distribution would be in a bad way; but this is all ancient history now, and we recur to the grounding question. Our contemporary, the *Electrical World*, adds: "In our opinion, considered merely as a safety precaution, the grounded neutral is decidedly to be recommended. It unquestionably requires a little more care than an ungrounded system, but it reduces the main risks very materially. Incidentally, it allows the safe use of working transmission voltages which otherwise would have to be classed as somewhat hazardous. What is more, those plants which have adopted the plan find that it causes far less inconvenience than they were prepared to meet. Whether a system should employ a star system which permits grounding is a question to be decided on its merits. Where a large secondary distribution is to be attempted, the saving in copper by using a star with neutral is so great that it will commonly be used whatever the connections back of it may be; and these latter connections should certainly be considered in the light of such possibilities as Mr. Peck has described. But in many cases the connection can be chosen without reference to any extended network, and the choice will generally fall on one of the mixed systems. Pure mesh connection in large plants has fallen into partial disuse, and the advantage, of which much was once made, in using two of the transformers to form a resultant mesh, has been proved to be of very little moment. Few who have tried it on a large scale would care to repeat the experiment, and on the scale of most recent plants the gain in using two transformers instead of three is negligible. At present the whole question is largely a matter of convenience."

Evaporation of Metals. — In the issue of the Chemical Society's *Journal* for the current month will be found a long abstract of a paper by Mr. F. Krafft on "The Evaporation and Boiling of Metals in Quartz-Glass and in the Electric Oven in the Vacuum of the Cathode Light." The observation that many substances boil quite regularly and at a definite temperature under the pressure of a column of their own vapour only in the vacuum of the cathode light, can be extended to metals by using suitable apparatus. For this purpose quartz vessels are invaluable, as they can be taken out from an electric furnace at 600deg. or 1,200deg., allowed to cool, and put straight back again without breaking, even when they contain metal; neither do they crack at the point at which the tube emerges from the furnace. They can be readily used for temperatures up to 1,200deg., and, with care, even at 1,200deg. to 1,400deg. Tight joints can readily be made which will maintain the cathode light vacuum, but as the vessels are attacked by oxides it is advisable to admit carbon dioxide or nitrogen rather than air when the vacuum is no longer needed. The use of an electric furnace is not only convenient, allowing as it does of a rapid and exact regulation of the temperature within 2deg. or 3deg. over a range from 14deg. to 1,400deg., but is, in fact, almost essential, as the quartz vessels do not project far from the furnace, and it is necessary that the wax which is used to make tight the joint should not be melted, as would inevitably be the case with any of the ordinary types of furnace. In the vacuum of the cathode light, zinc sublimes so rapidly, even at 300deg., that the upper part of the vessel becomes covered with an opaque layer of metal in the course of a few seconds; actual boiling occurs when the temperature outside the tube is about 640deg., and the process is very rapid, 5 grm. being distilled in 30 minutes. In a large apparatus it should be possible to distil a kilogramme of zinc at constant temperature and in quite a short time. Cadmium begins to sublime at 322deg, and boils when the temperature of the oven is 474deg. Selenium distils quickly at 380deg., whilst tellurium begins to sublime at 430deg, and boils at 555deg. Lead begins to evaporate at about 1,000deg., and at 1,180deg. (temperature of oven) boils vigorously. Tin is much less volatile and does not show any sign of evaporating at 1,100deg. Antimony evaporates freely at 670deg., and rapidly distils at 775deg. to 780deg. Bismuth begins to evaporate at 540deg. and boils at 1,045deg. to 1,050deg. Silver evaporates very rapidly near its melting point, but does not boil at 1,229deg.—the highest temperature of the experiment; a second experiment showed a very rapid evaporation at 1,340deg., but no boiling. Copper evaporates at about 1,300deg., but probably would not boil below 1,500deg. or 1,600deg. Gold is even less volatile than copper, and shows only a slight evaporation at 1,375deg.; it might boil at about 1,800deg. It is notable that the boiling points are in the order of the valencies, and not of the atomic weights of the metals. The actual temperatures at which the metals boil depends on the temperature of the oven and also on the height of the vapour column, which can be easily varied by raising or lowering the distilling tube in the furnace, since complete condensation takes place immediately outside the furnace. The boiling point of cadmium under a 6cm. column of vapour rose from 424deg. to 450deg. as the temperature of the oven was raised from 462deg. to 540deg., under a 9cm. to 10cm. vapour column from 435deg. to 480deg. (oven temperature 488deg. to 583deg.), and under a 13cm. to 14cm. column from 430deg. to 474deg. (oven 485deg. to 589deg.); the boiling point thus rises regularly with the height of the vapour column, but only rises relatively slightly when the temperature of the oven is raised considerably. With the oven temperature at 714deg., zinc boils at 545deg. under a vapour column of 60mm., at 553deg. under 100mm. of vapour, and at 560deg. under 135mm. of vapour. With a furnace temperature of about 1,100deg., bismuth boils at 994deg. under 60mm., at 1,014deg. under 90mm., and at 1,045deg. under 135mm. of vapour. Antimony under a short vapour column boils at 735deg. (oven 778deg. to 780deg.). Under a short vapour column, lead boils at 1,140deg. to 1,142deg. (oven 1,226deg.), under 45mm. of vapour at 1,172deg. to 1,173deg. (oven 1,225deg.).

LONDON UNITED ELECTRIC TRAMWAYS.

BY B. PONTIFEX.

The enormous development of the tramways in the West of London since the adoption of electric traction is very well set forth by a list of the sections open to traffic, those authorised and under construction, and the proposed extensions, together with their many connections with other railway and tramway systems, now either in actual operation or under construction.

Sections of the London United Electric Tramways Open for Traffic.—Shepherd's Bush to Southall; Shepherd's Bush to Hounslow; Shepherd's Bush to Twickenham, Hampton, and Hampton Court Palace; Hammersmith Broadway to Hounslow; Hammersmith to Twickenham, Hampton, and Hampton Court Palace; Richmond Bridge to Twickenham, Teddington, Kingston Bridge, and Hampton Court Palace; and Kew Bridge to Richmond.

Authorised Extensions.—Acton to Willesden; Southall to Uxbridge; Hammersmith to East Acton; Richmond to Hammersmith Bridge, *vid* Barnes and Mortlake; Hounslow to Cranford; Hounslow to Kempton Park; Twickenham to Kempton Park; Hampton to Molesey, Thames Ditton, Surbiton, Talworth, and Hook; Kingston to Surbiton; Kingston to Kingston-hill; and Kingston to Tooting, *via* New Malden, Raynes Park, and Wimbledon.

Proposed Extensions.—Cranford to Slough and Maidenhead; and Hounslow to Staines and Virginia Water.

That the above systems will be of the greatest use in opening up the districts through which they pass is clearly shown by the following tables of fares and distances covered by the London United and their business allies, the Metropolitan District Railway, and compared with those of opposition routes; the average fare per mile, as shown in the tables below, being 0·4d. against 0·76d., with the average mileage per 1d. at 2·29 miles as against 1·33 miles. The map (Fig. 1) also shows the special facilities for intercommunication between the London United Electric Tramways and the various branches of the District Railway and the allied "tube" railways, by means of which direct communication will be established between different suburban districts which at present are only served by roundabout routes.

The site of the central power-house at Chiswick, together with those of the sub-stations and car depôts at Fulwell, Hounslow, Hanwell, and Acton, are indicated by the

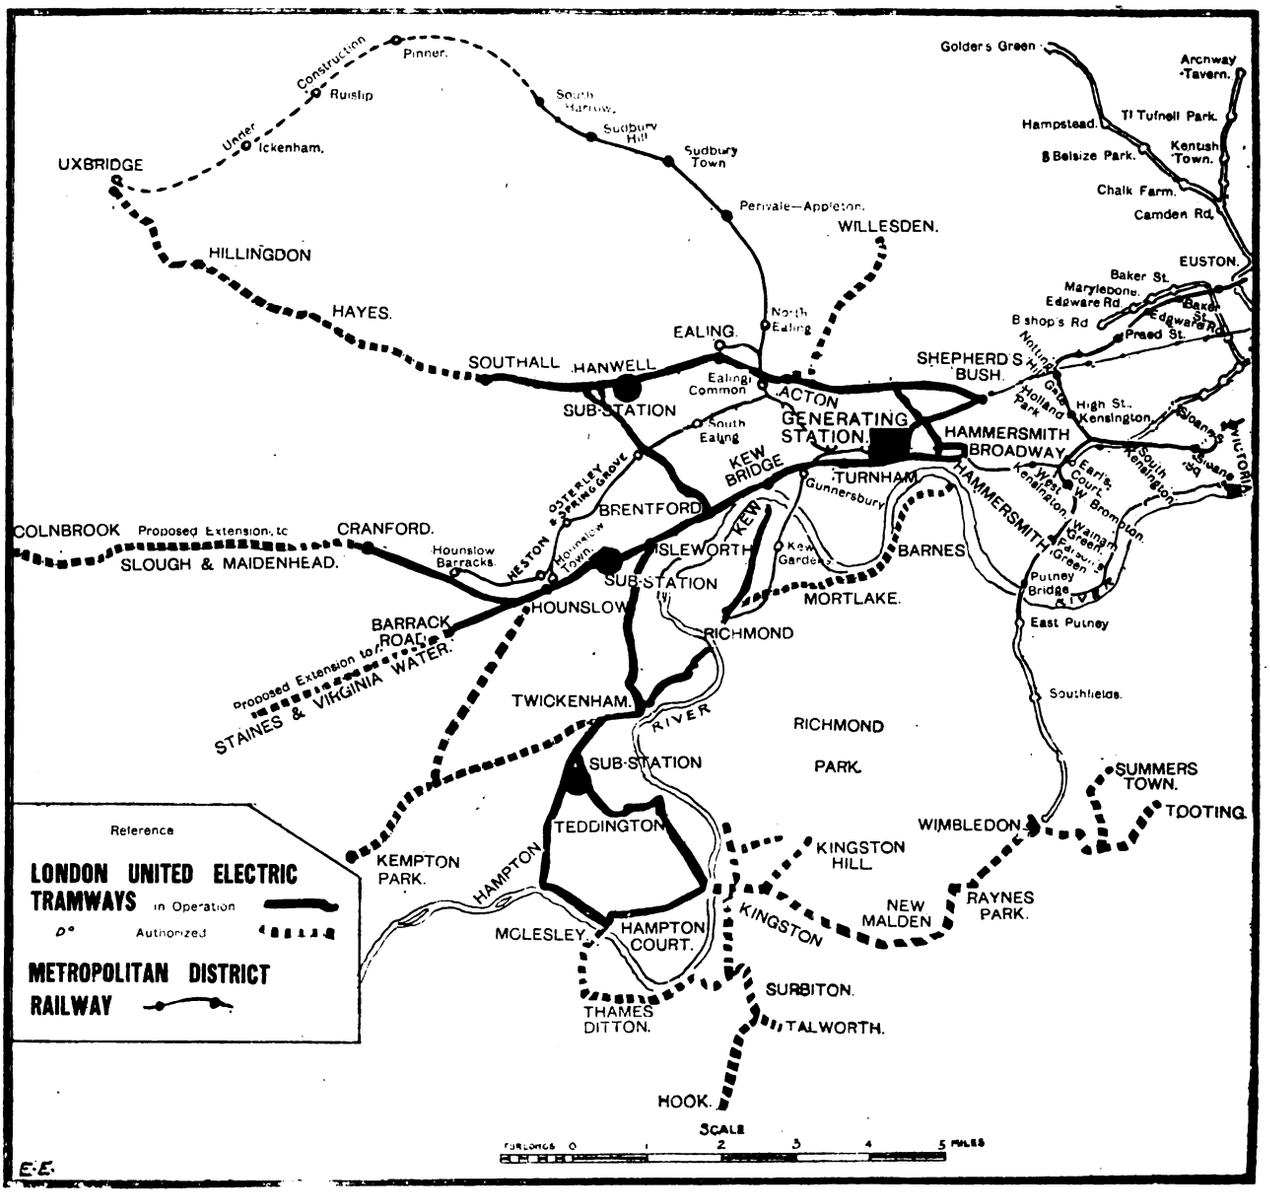

FIG. 1. Map of the Tramway System of the London United Tramways Company.

small black squares and circles. Their equipments will be described in detail, but the following list of the size and capacity of each will give a good idea of the amount of traffic handled by these lines:

	Cars.	Converters. Number.	Converters. Size.
Acton car-shed	30	—	—
Hanwell car-shed	70	3	300 kw.
Hounslow ,,	50	2	300 kw.
Fulwell ,,	200	3	500 kw.
Chiswick ,,	75	1	500 kw.
Chiswick power station			3,500 kw.-4,000 kw.

The plant at Chiswick power-house (Figs. 2, 3, and 4) is arranged in the following manner.

BOILER-HOUSE.

There are 11 Babcock and Wilcox boilers in one row

The table shows the maximum journey obtainable, but the average fare per mile and average mileage per penny given is that of the whole of the journeys combined.

The sections of the Metropolitan Railway shown on the diagram are the northern half of the Inner Circle and the section under construction from South Harrow to Uxbridge, over which the District Railway has running powers.

down the boiler-house, each capable of evaporating 11,000lb. per hour. Ten are fitted with two furnaces, but the last boiler has only one, though the grate area is the same—namely, 60 square feet—a result that is obtained by doing away with the dividing wall between the furnaces and proportionately decreasing the over-all width of the boiler. Each boiler has 140 4in. tubes with wrought-steel headers, two water-drums, and a cross steam-drum. They are all fitted with the Hopkinson water alarm, which acts both at high and low water level Stoking is carried out by means of Vicars's mechanical stokers, the gear for which is driven by two 10-h.p. electric motors through worm gear, one motor at each end of the boiler-house. All the coal is delivered to the stokers from overhead bunkers, and is raised by an electrically-driven Hunt conveyor, which is also used to remove ashes on the lower half of the run. The coal for each boiler is automatically weighed before falling into the stoker hoppers (Fig. 5). The fire-bars are cooled by means of fine steam jets playing on both the back and front of each grate. The burnt gases pass into an overhead brick-lined steel flue with a Green's economiser of 340 4¼in. tubes, fitted with motor-driven scrapers. Contrary to the usual practice, the flue does not lead into the chimney at the ground level, but at a height of 40ft. above it. This enables the draught to be more thoroughly checked by the economiser tubes, and avoid the sometimes heard complaint that economisers require more forced draught or a taller chimney. The chimney itself is of steel, lined with firebrick for three-quarters of its height, and reaches a height of 260ft. The feed water is softened by the Archbutt-Deeley process, and is delivered to the boilers by three-throw Blake-Knowles feed pumps. The working pressure is 160lb. per square inch,

ENGINE-HOUSE.

Generating Plant.—(*a*) Two Allis vertical cross-compound engines (Fig. 6) are each coupled to two 250-kw. G.E. traction generators, arranged one on each side of the flywheel, so that each set is really a 500-kw. generator. The engines are fitted with the Reynolds-Corliss valve gear with pneumatic dashpots; the cut-off on both high and low pressure cylinders is controlled by a belt-driven governor. There is also a supplementary governor which at six revolutions per minute above the normal releases a weight by means of a trigger catch, and so works a throttle valve which shuts steam completely off the engine. The diameter of the high-pressure cylinder is 22in. and the clearance 2 per cent., and of the low-pressure cylinder 44in. and 4 per cent. The length of stroke is 42in., and the engines run at 90 revolutions per minute. The valves,

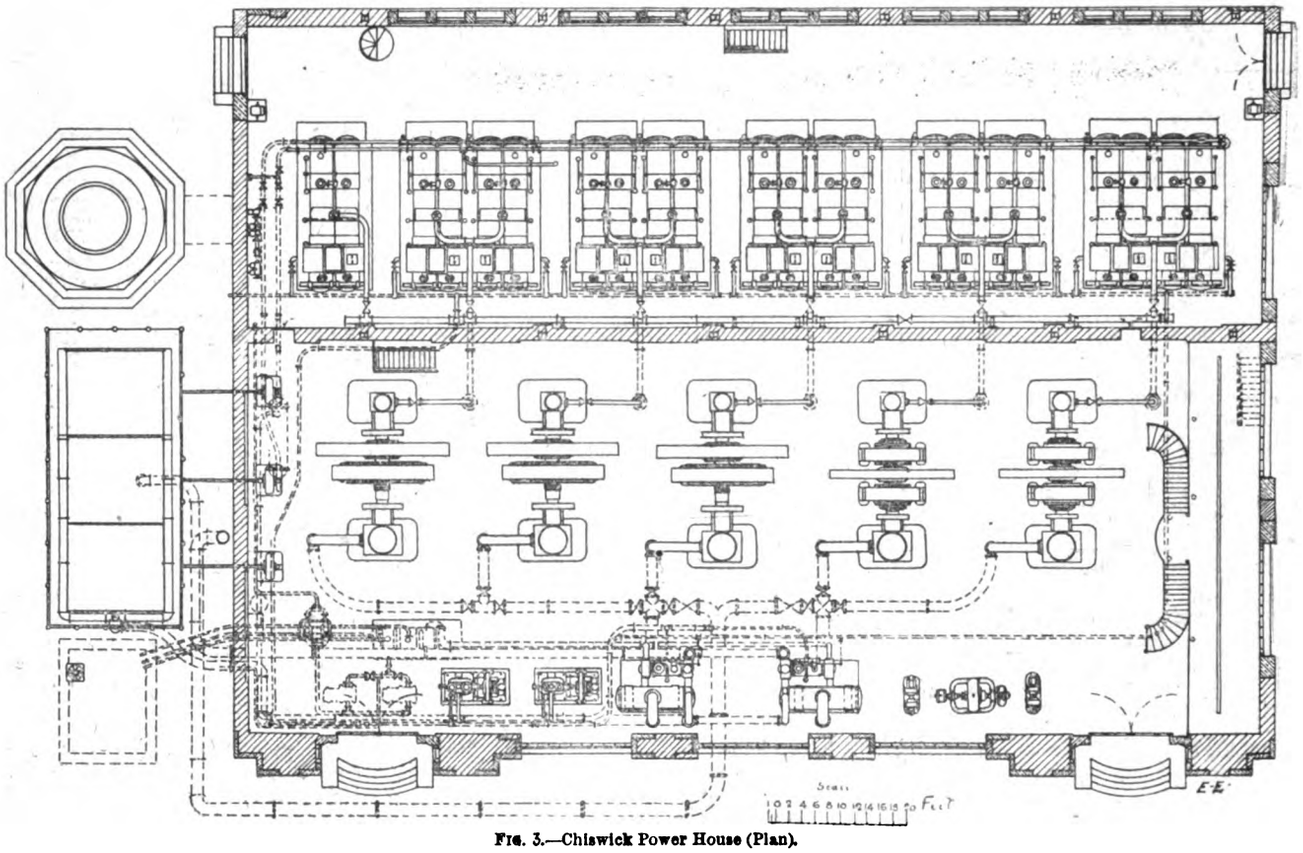

FIG. 3.—Chiswick Power House (Plan).

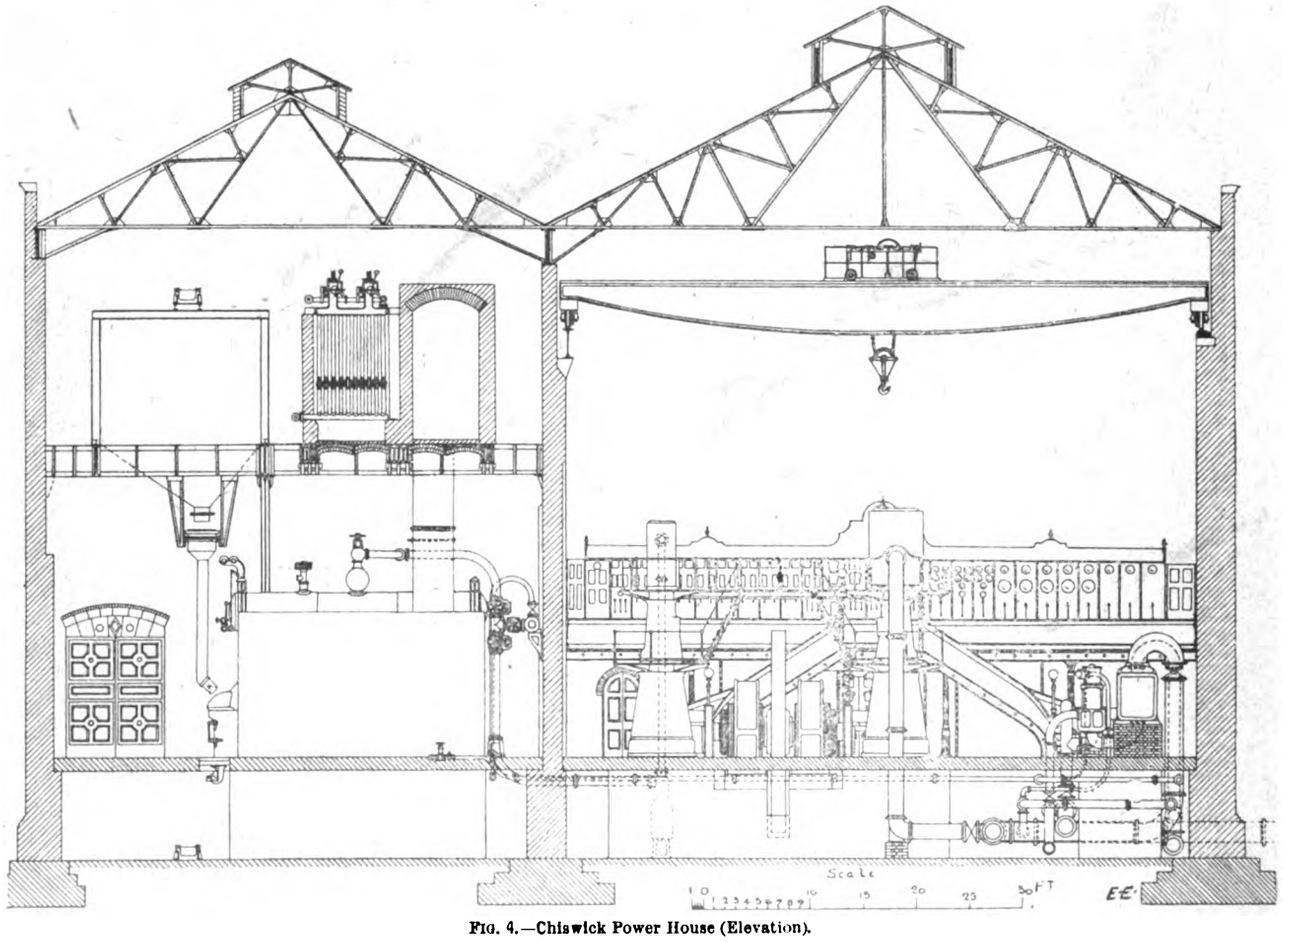

FIG. 4.—Chiswick Power House (Elevation).

Digitized by Google

which are driven by the usual T-headed rocking spindle working off a wrist plate, are situated in the cylinder covers. The cylinders and receivers are lagged with asbestos and covered with steel plates. The receivers

at 94 revolutions per minute. These machines have a stationary armature, star-wound, with the middle point earthed, giving an output of 98 amperes per phase with a frequency of 25 cycles per second at 5,000 volts. The

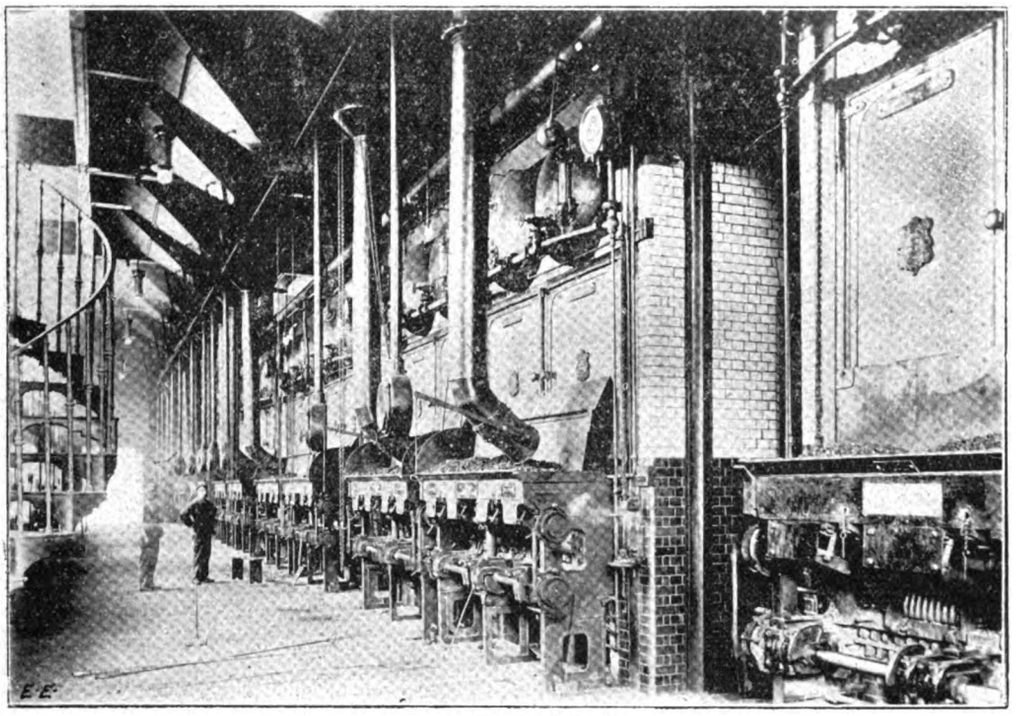

FIG. 5.—Chiswick Boiler House.

between the high and low pressure cylinders are fitted with reheater tubes round which live steam is passed; the outlet from the reheater is controlled by a steam-trap.

The traction generators are compound machines giving

fields are of the revolving flywheel type, and are 32-pole, with cast-iron slip-rings and carbon brushes for the field current, which is 15 amperes at full load and 13 amperes at no load. The field current is taken from the running

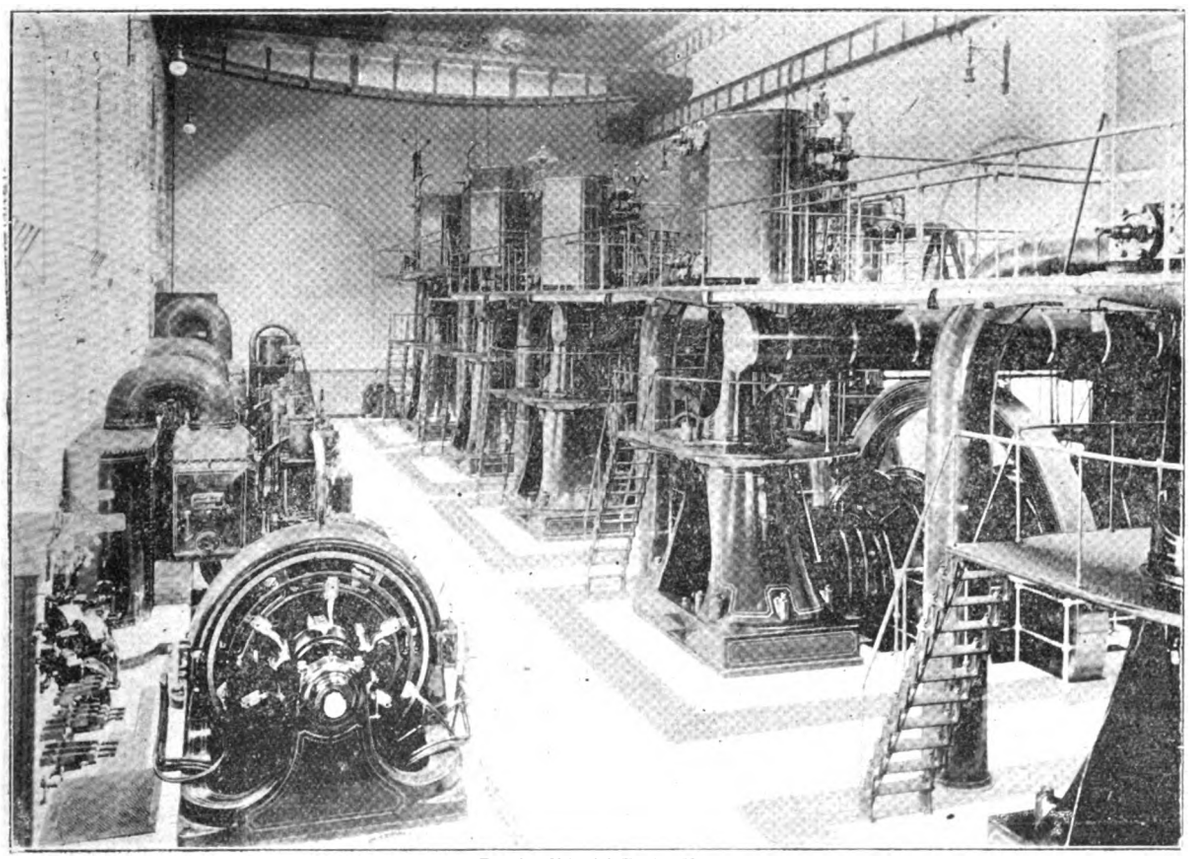

FIG. 6.—Chiswick Engine House.

500 amperes at 500 to 550 volts, and have often run at a continuous overload of 25 per cent., and can do 50 per cent. on an emergency. They are eight-pole machines; armature diameter is 5ft. 2in. and that of commutator = 4ft. 3in.

(*b*) One Allis engine of same size and type as above is coupled to a 500-kw. three-phase G.E. alternator running

direct-current generator, being tapped off the machine side of the negative circuit breaker and protected with a 200-ampere Peard fuse. This machine is capable of running under similar conditions of overload to those of the direct-current generators.

(*c*) Two 1,000-kw., 5,000-volt, three-phase alternators

Digitized by Google

are coupled to two Allis cross-compound vertical engines, both engines and alternators being of the same type as previously described. The diameter of the high-pressure cylinder is 26in., and of the low-pressure cylinder 54in. The stroke is 48in., and the speed 94 revolutions per minute. These larger engines have water-jacketed guides and main bearings, and the wrist plates which carry the eccentric motion to the exhaust and steam valves are fixed on separate spindles. In this respect they differ from the 500-kw. type, which are not water-jacketed, and have both wrist plates working on one spindle. In other respects the design is similar. All the main engines are fitted with hand adjustment on the low-pressure cut-off for use if desired as an alternative to governor regulation. The diameter of the field is 32ft., and the field current is 30 amperes at full load and 26 amperes at no load. The amperes per phase are 116, and the frequency is 25 cycles per second.

There is also a 75-kw. Belliss compound enclosed engine, coupled to a B.T.H. 150-ampere 500-volt machine, running at 400 revolutions per minute. This is used for depôt lighting and motors at times when the larger engines are not running.

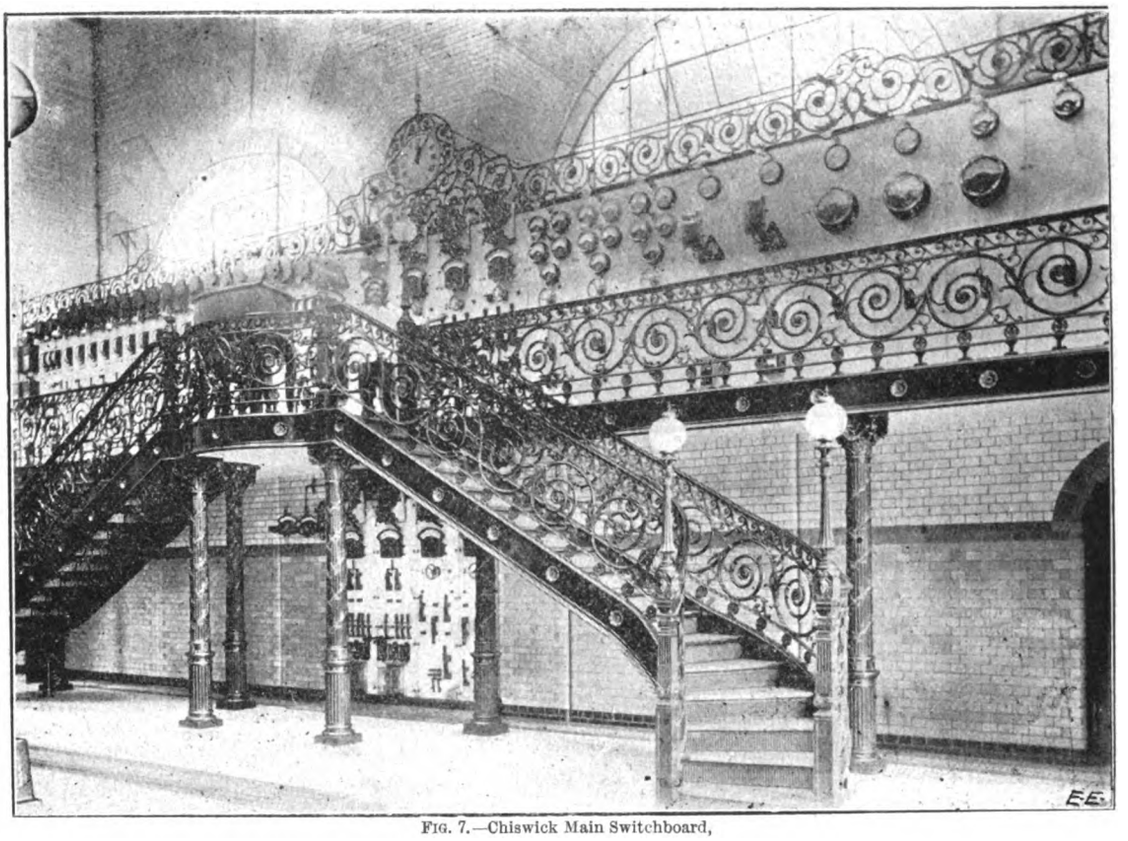

FIG. 7.—Chiswick Main Switchboard.

Condensing Plant.—There are two Wheeler condensers, each of 1,600 square feet tube area, and capable of dealing with 32,000lb. of steam per hour. These have double-acting vertical air and circulating pumps, worked from one rocker shaft and fitted with hard rubber valves. The pump rods are solid Tobin bronze, and the plungers have Tuck's canvas packing. The condenser tubes are $\frac{5}{8}$in. internal diameter by 10ft. length. Also one Wheeler condenser, similar to above, but capable of dealing with 40,000lb. of steam per hour, with a tube area of 2,200 square feet. Three Barnard-Wheeler cooling towers deal with the discharge from the above condensers. The fans for each tower are driven by a direct-coupled electric motor of 35 h.p. The hot-well is enclosed. Two three-throw Blake-Knowles pumps driven by 5-h.p. motors discharge water from the hot-well through Railton and Campbell filters to the feed tanks over the boilers. Between the exhaust main and each condenser is fitted a Baker oil separator, in which the steam on its way to the condenser is brought in contact with a body of standing water at the bottom of the separator, and afterwards passes through angle-iron baffles, which remove the grease and moisture. This increases the volume of liquid in the separator, and an overflow continually falls from a pipe which leads to a small pump, by means of which the mixture of grease and water is forced into a settling tank. Here the oil rises to the surface, and after filtering is used

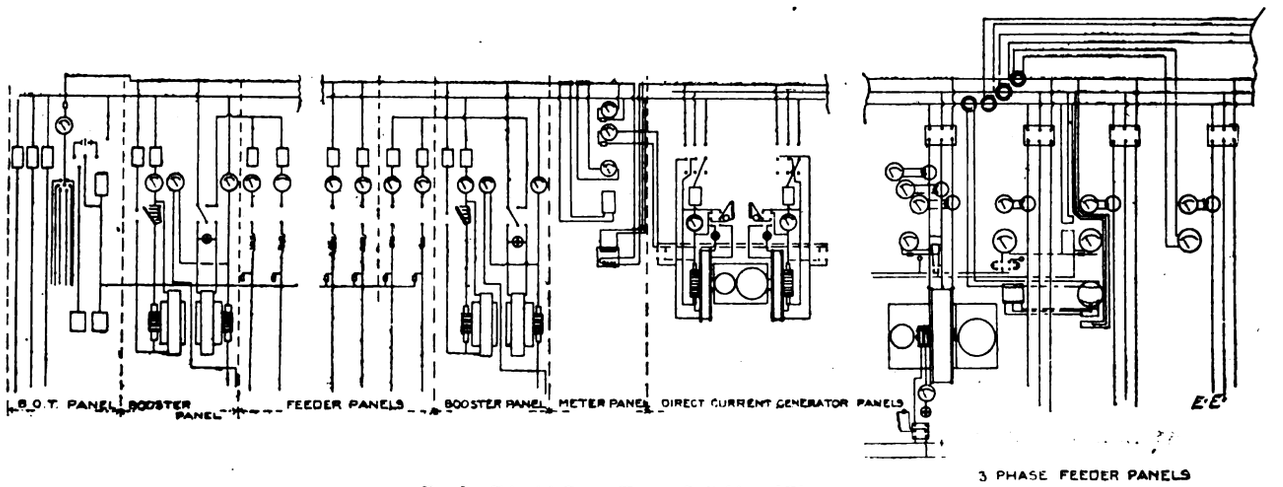

FIG. 8.—Chiswick Power House—Switchboard Diagram.

Digitized by Google

for pumps, etc. These separators are found to be most effective. Any small quantity of grease that may escape is dealt with by means of the Railton and Campbell filters on its way to the feed tanks, as mentioned previously.

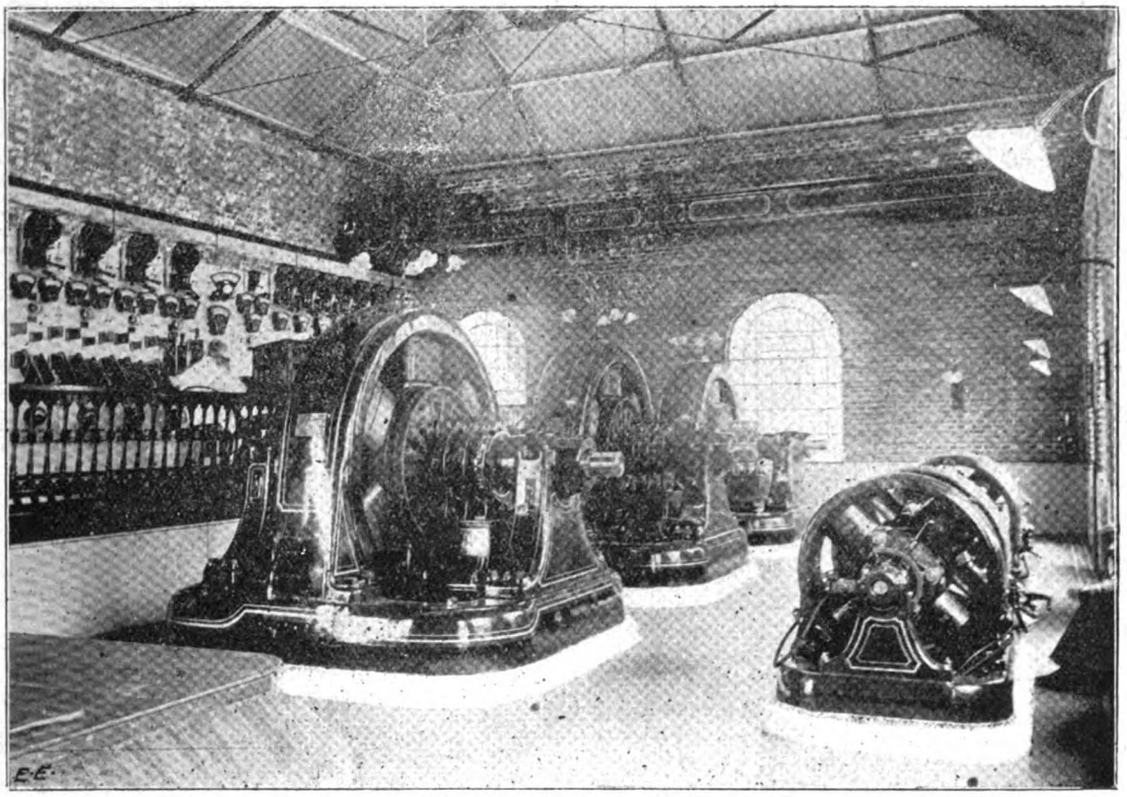

FIG. 9.—Fulwell Sub-Station—Interior.

Four Warden oil filters are used to filter the spent oil from all engines.

Auxiliary Electrical Plant.—A 500-kw. rotary converter (Westinghouse six-pole machine), running at 500 revolutions per minute, is supplied with three-phase alternating current by six 100-kw. Westinghouse static transformers, coupled two in parallel on each phase. This machine is to enable the alternating plant to help the direct current, or *vice versâ*. When running direct current to alternating current, the rotary field is excited by a small motor-generator, the induction motor of which is driven from the slip-ring current from the rotary. By this means the speed of the rotary is kept constant. The pole-faces of the rotary have copper shoes fitted to prevent surging. There are also two negative boosters, 15 kw., giving 300 amperes at 50 volts on the generator side, and driven by direct-coupled 500-volt motors. The generator field is excited by the current passing through the positive feeder of the district to which the negative cable of the booster is connected. The regulation obtained by this means is quite automatic.

Main Switchboard.—This is composed of 27 panels (Fig. 7), arranged along a gallery at the southern end of the engine-room, as follows: One Board of Trade panel, with testing ammeter, earth-current recorder, and three recording voltmeters for registering the potential difference along the rail; two negative booster panels; eight direct-current feeder panels, two feeders per panel, with circuit breakers, switches, and lightning arresters; one meter panel, with main and recording ammeters, two main voltmeters, and one direct-current wattmeter; four direct-current generator

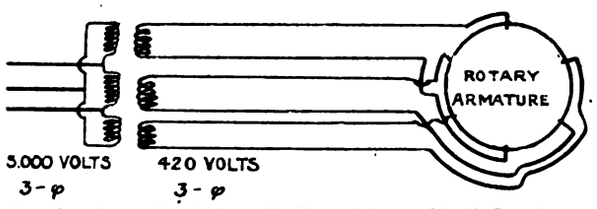

FIG. 10A.—Connections between Six-Phase Rotary and Static Transformers.

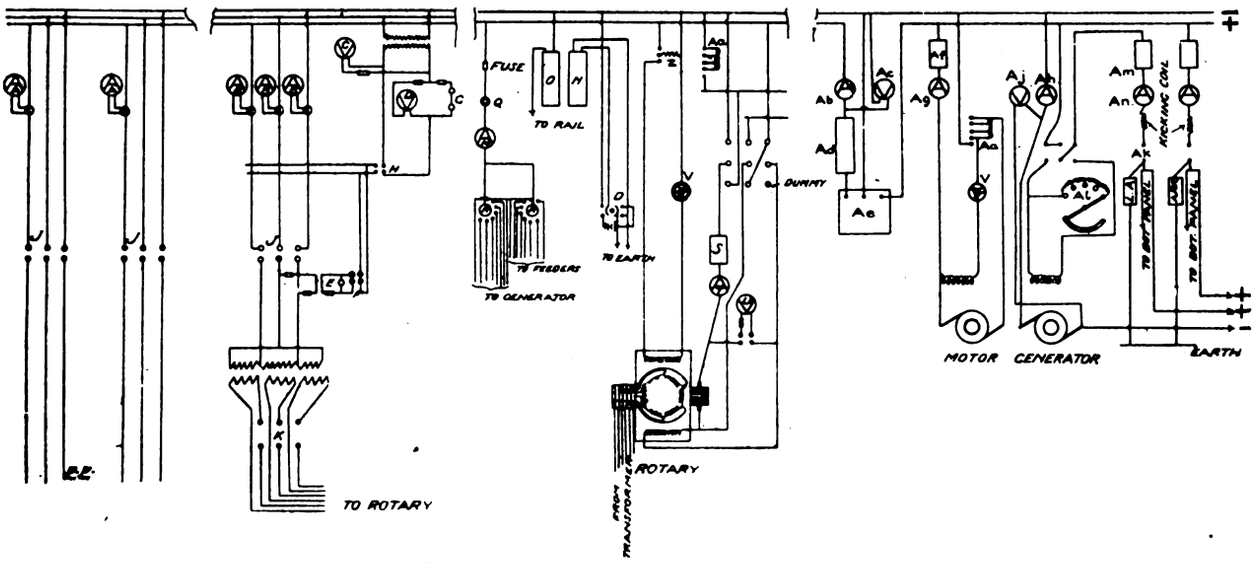

FIG. 10.—Fulwell Sub-Station—Switchboard Diagram.

Digitized by Google

panels of B.T.H. standard pattern, with circuit breakers; three alternate-current generator panels, each with a lever working a 200-ampere oil-break switch, a carbon-break field switch, voltmeter (5,000 volts), and three ammeters; six high-tension feeder panels, each controlling one feeder to the sub-stations, with one oil-break switch and one ammeter; two high-tension panels controlling the transformers, used with the 500-kw. rotary. There are also, fitted on swinging brackets, main ammeters, main and synchronising voltmeters, and integrating wattmeters.

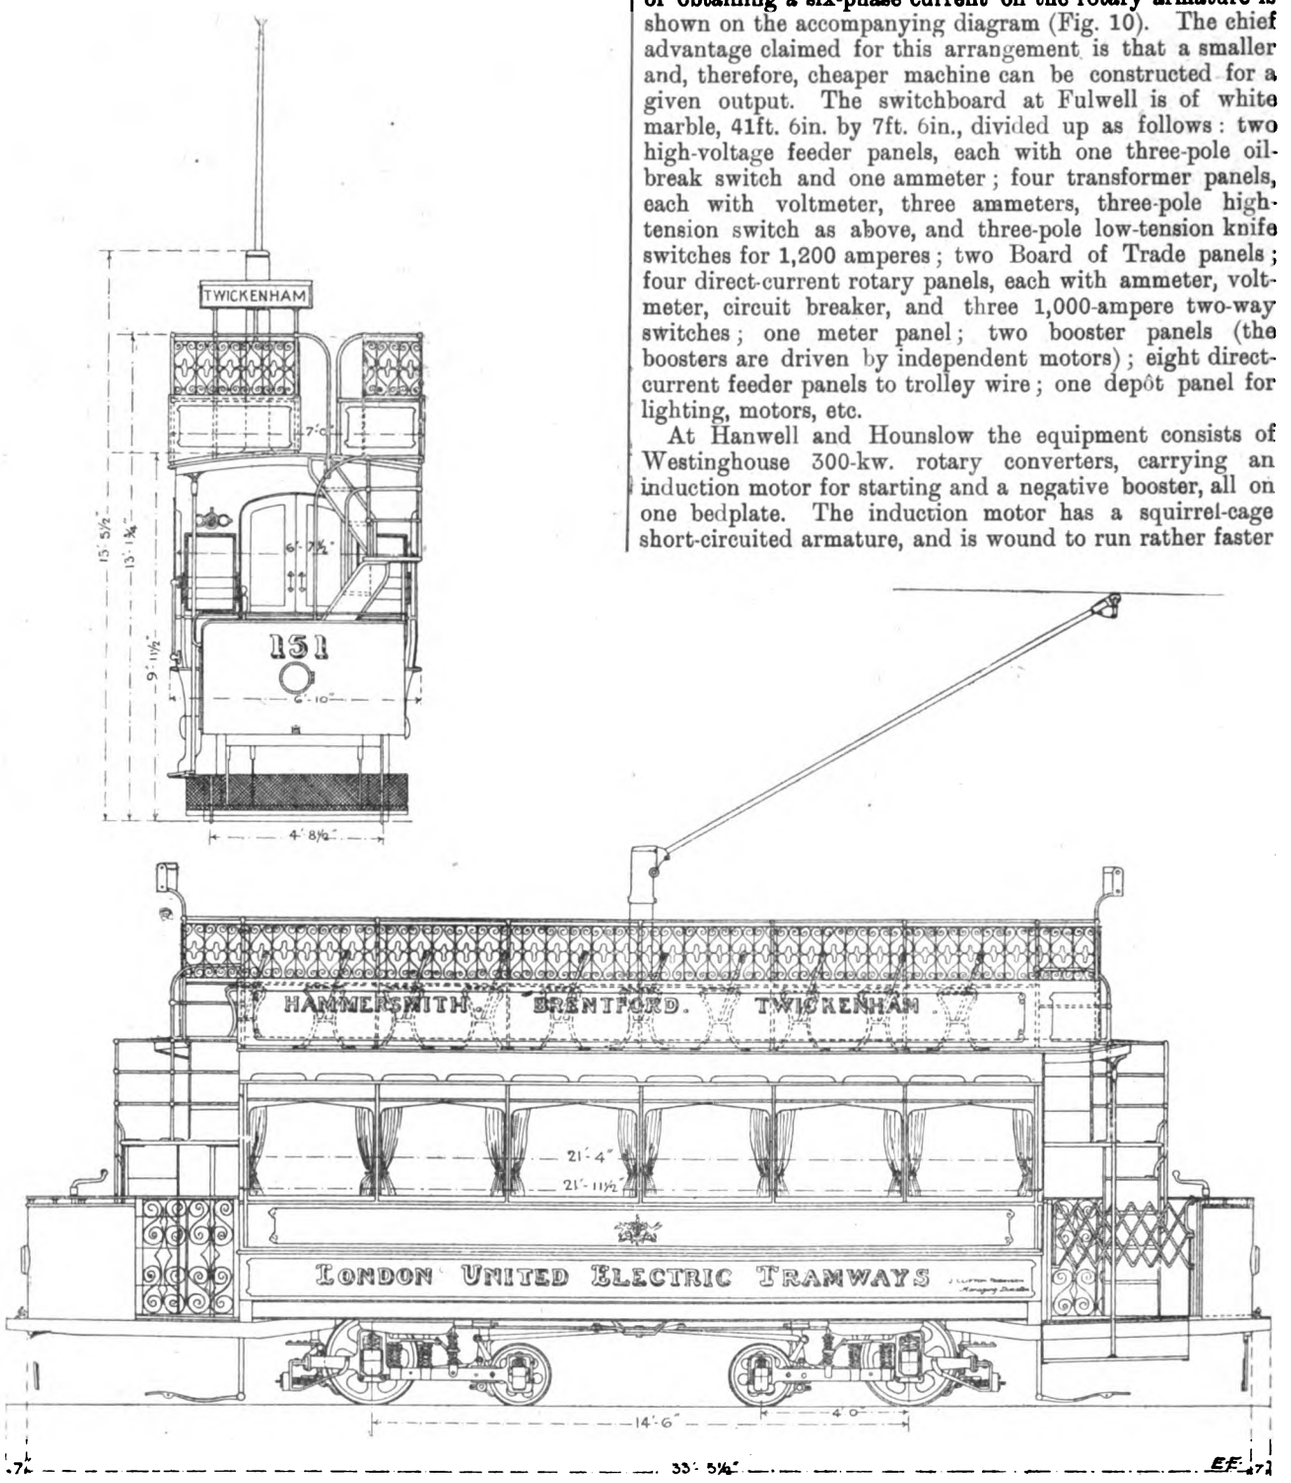

FIG. 11.—Typical Car on the London United Tramways System.

Auxiliary Switchboards.—Rotary board: The low-tension alternate-current and direct-current panels for the 500-kw. rotary are fixed close by it, and are of standard Westinghouse pattern. There is also a board of four panels, arranged as follows: the first panel controlling the depôt lighting, the second the depôt motors, the third the fan motors for cooling towers, and the fourth for the 75-kw. generator set.

Sub-Stations.—From the power-house at Chiswick three-phase current at 5,000 volts is supplied to the sub-stations over three-core, lead-covered, paper-insulated cables laid in stoneware conduits. These sub-stations are situated at Fulwell (between Twickenham and Hampton), Hounslow, and Hanwell.

The Fulwell sub-station (Fig. 9) is the most recently opened and has an equipment of three 500-kw. six-phase rotary converters, by the British Thomson-Houston Company. There are three 200-kw. static transformers, which supply current to each of the converters at a pressure of 420 volts, making a total of nine transformers; the method of obtaining a six-phase current on the rotary armature is shown on the accompanying diagram (Fig. 10). The chief advantage claimed for this arrangement is that a smaller and, therefore, cheaper machine can be constructed for a given output. The switchboard at Fulwell is of white marble, 41ft. 6in. by 7ft. 6in., divided up as follows: two high-voltage feeder panels, each with one three-pole oil-break switch and one ammeter; four transformer panels, each with voltmeter, three ammeters, three-pole high-tension switch as above, and three-pole low-tension knife switches for 1,200 amperes; two Board of Trade panels; four direct-current rotary panels, each with ammeter, voltmeter, circuit breaker, and three 1,000-ampere two-way switches; one meter panel; two booster panels (the boosters are driven by independent motors); eight direct-current feeder panels to trolley wire; one depôt panel for lighting, motors, etc.

At Hanwell and Hounslow the equipment consists of Westinghouse 300-kw. rotary converters, carrying an induction motor for starting and a negative booster, all on one bedplate. The induction motor has a squirrel-cage short-circuited armature, and is wound to run rather faster than the ordinary speed of the rotary, which is by this means quickly brought up to phase, and can be easily switched in. The direct-current side of the switchboard is similar to that at Fulwell, though smaller, but the high-voltage three-phase panels are fitted with Westinghouse long-break three-pole switches, each pole fitted with a separate circuit breaker, instead of the oil-break switches in use at Fulwell.

There are three rotary converters at Hanwell and two at Hounslow. The high-voltage three-phase current is

Digitized by Google

transformed down to 340 volts for delivery to the converters, by means of Westinghouse oil-insulated 100-kw. transformers, three to each rotary. At each sub-station there is a small motor-driven Reavell air-compressor for cleaning purposes.

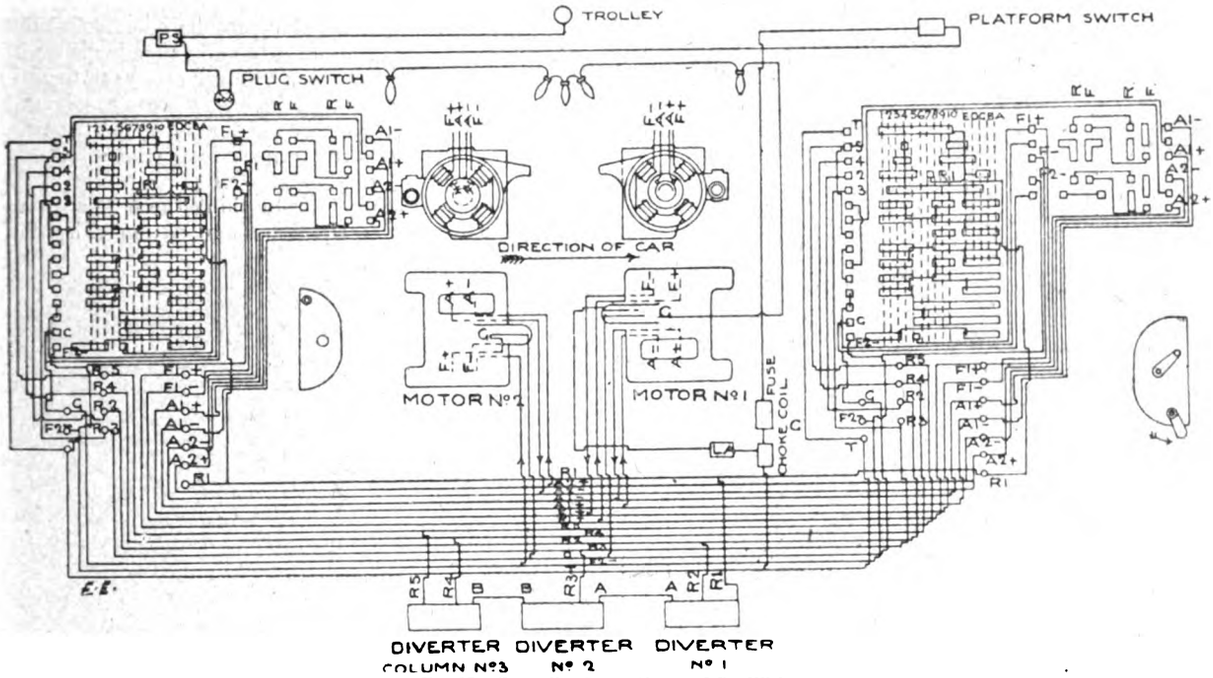

FIG. 12.—Controller Connections and Car Wiring.

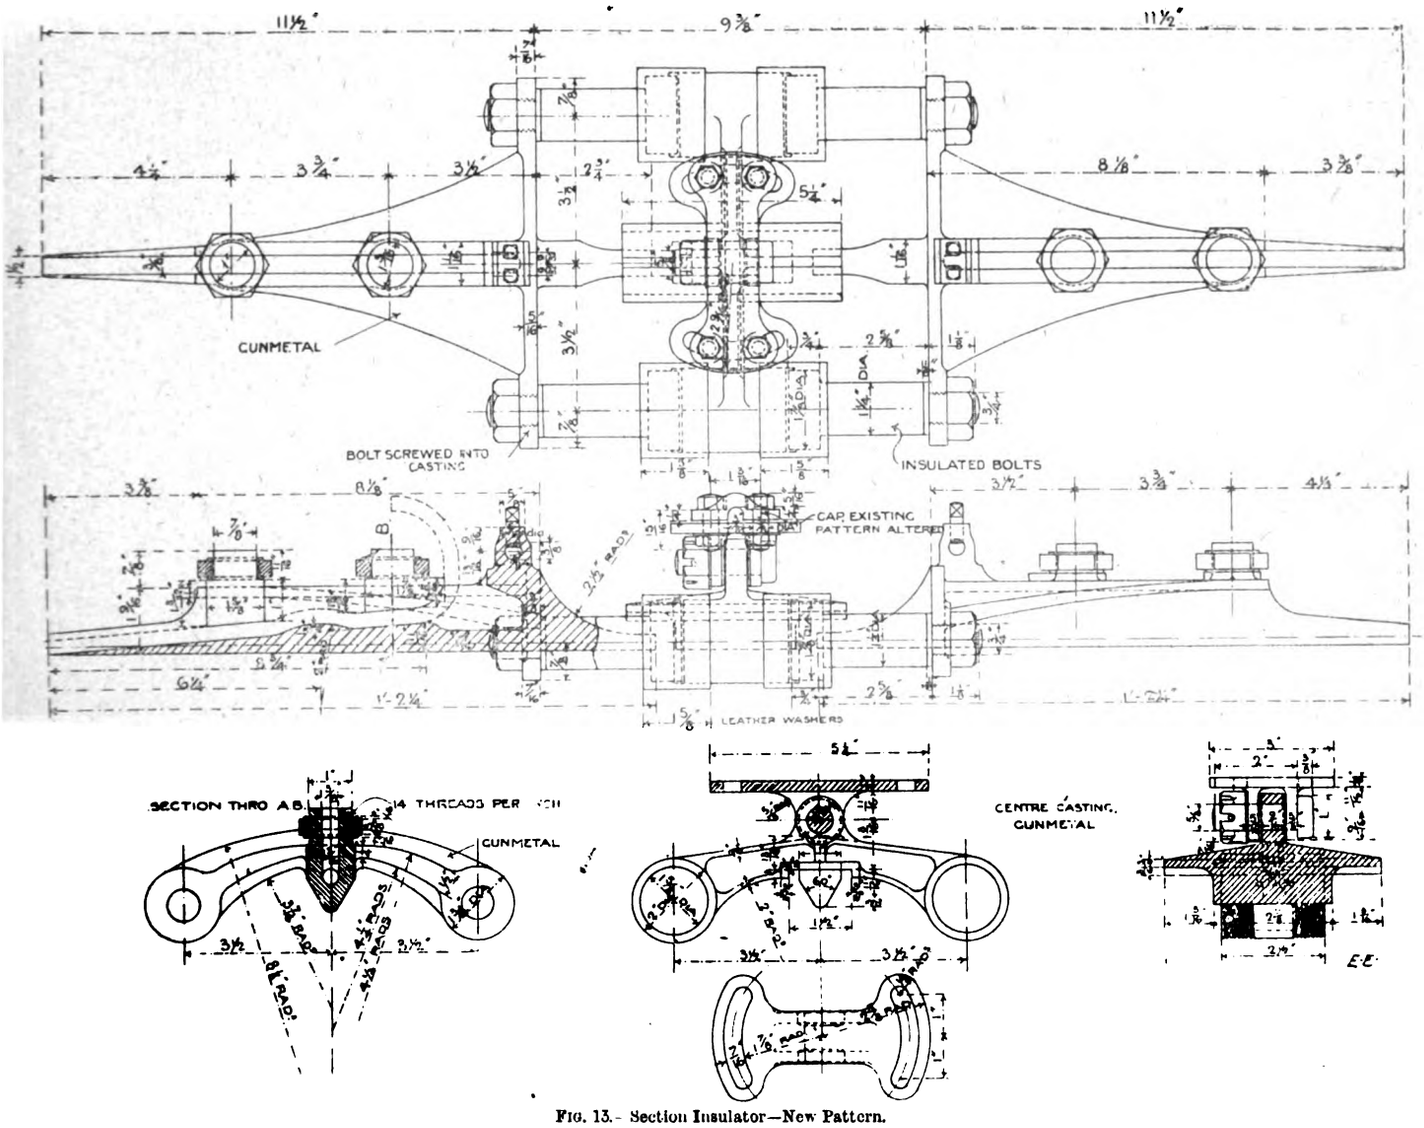

FIG. 13.—Section Insulator—New Pattern.

CAR DEPOTS.

These are placed as follows: Chiswick—car shops for repairs, painting, etc., and stabling for 75 running cars; Acton (old horse-car depôt)—30 cars; Hanwell—70 cars; Hounslow—50 cars; Fulwell—200 cars. In all there are 300 cars in use, but without any fresh depôts there is accommodation for 125 more.

CARS.

The cars in use on this system are all of the double-deck

Digitized by Google

pattern, with maximum traction trucks (Fig. 11). Messrs. Hurst, Nelson, and Co., of Motherwell, N.B., built 100, and

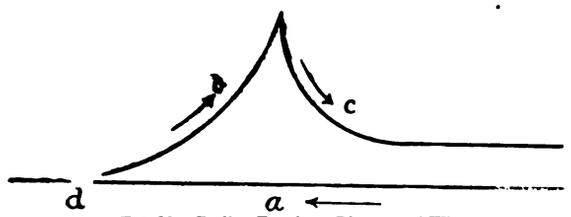

FIG. 14.—Trolley Turning—Diagram of Wire.

these are fitted with Peckham trucks carrying 58-G.E. motors and B-18 controllers supplied by the British Thomson-Houston Company. Messrs. Milnes and Co., of Birkenhead, constructed 150, and all of these have Westinghouse equipments, 49 B motors, and No. 90 controllers, but 50 have the M'Guire truck, while the balance are carried on Brill maximum traction trucks, as also are 25 cars built by the British Electric Car Company and fitted with Westinghouse motors and controllers. Throughout all the cars destination indicators have been fitted by the British Electric Car Company, these being their standard pattern with transparent names on canvas, which can be moved over rollers to change the destination indicated, which is rendered visible at night-time by two incandescent lamps, which also serve the purpose of illuminating the top of the car. The interiors of the cars are very handsomely got up with dark and light oak moulding, with maple panels, and the seats provided are an object lesson in comfort for nearly all the tramways in the kingdom, while the passengers on a few railways would think the millennium was at hand if they received equal accommodation. The Wood's

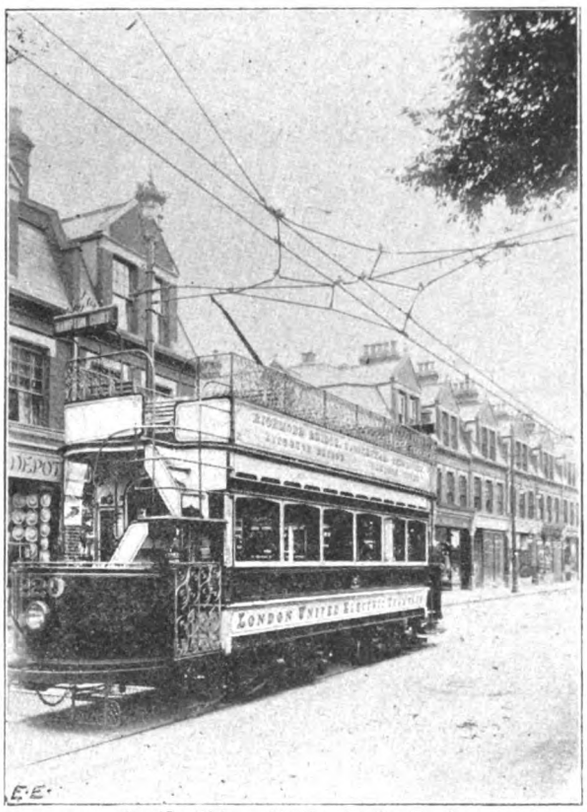

FIG. 15.—Richmond Bridge—Trolley Turning.

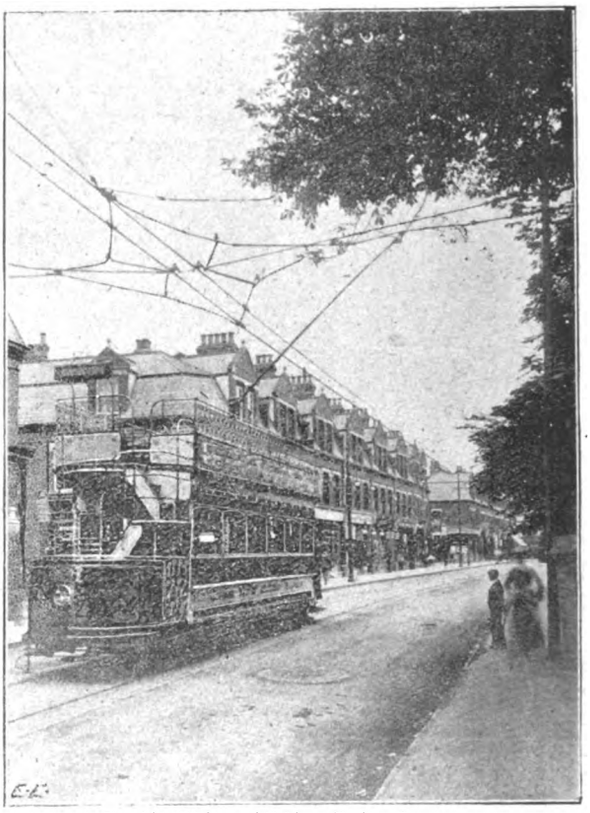

FIG. 16.—Richmond Bridge—Trolley Turning.

swivelling trolley head is in use throughout the system, and similar advantage is taken of the Wilson-Bennett lifeguard.

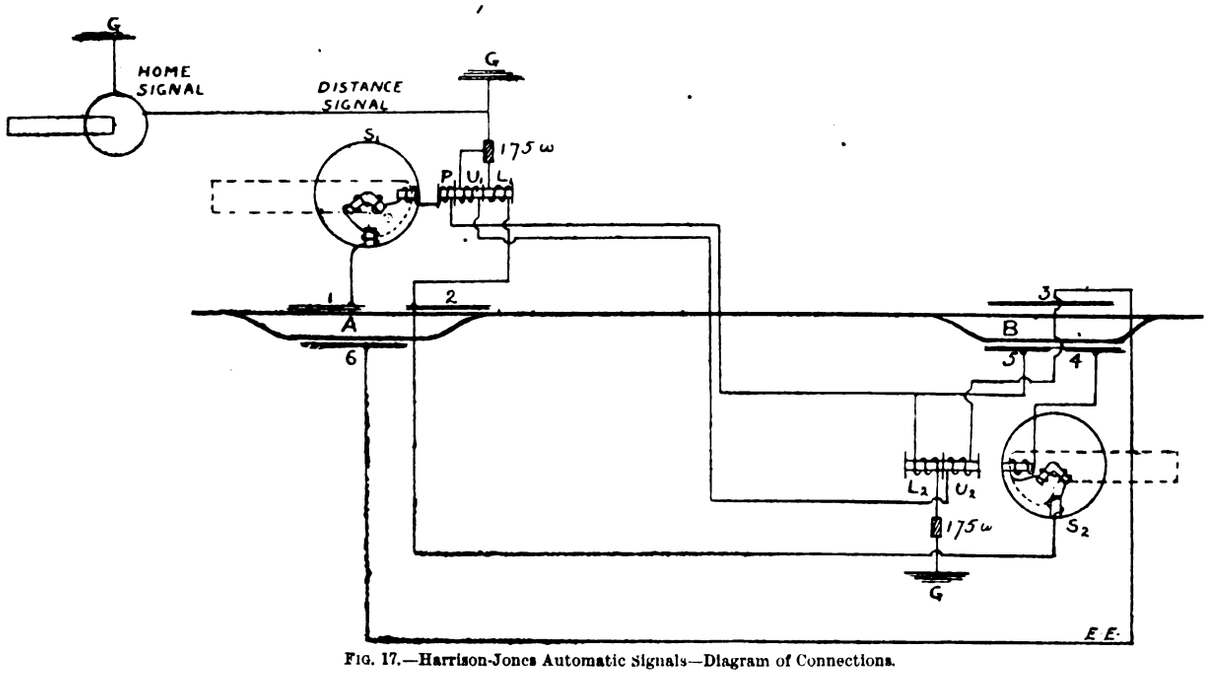

FIG. 17.—Harrison-Jones Automatic Signals—Diagram of Connections.

The vexed question of brakes does not cause much trouble on a line over flat country such as the London United Electric Tramways Company traverse, therefore

Digitized by Google

the cars only carry the ordinary ratchet hand brake and the electric short-circuiting brake, but two cars have been fitted with magnetic brakes, one supplied by the British Thomson-Houston Company, and the other by the Westinghouse Company, for the purpose of experiment. Chilled cast-iron brake-blocks and wheels are used on all cars on the system.

Three water-carts mounted on single trucks are kept at work in dry weather. These are only used for watering the rails, since the various district councils have not yet grasped the economy of motor-driven water-carts on roads through which the tramlines pass.

Overhead Work, etc.

The overhead work is of the ordinary standard construction, carried by span wires from side poles or from

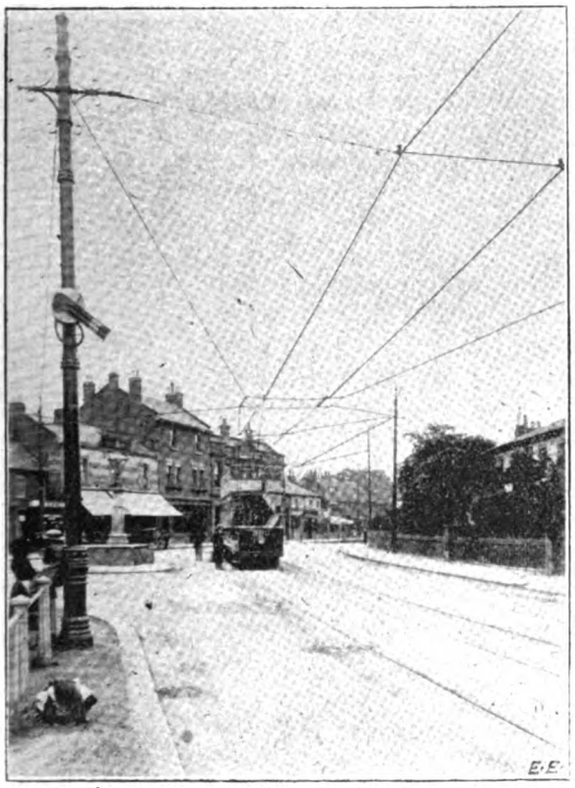

Fig. 18.—Automatic Signalling at Heath-road, Twickenham.

rosettes on buildings in narrow roads by centre poles (through Ealing), or by side bracket poles, as circumstances require. Apart from this there are some interesting features that are somewhat different from ordinary practice.

each section, with a corresponding saving of time when any section has to be isolated, whether owing to an accident or for ordinary routine work.

The accompanying drawing (Fig. 13) shows the details of the new section insulator which is being adopted in

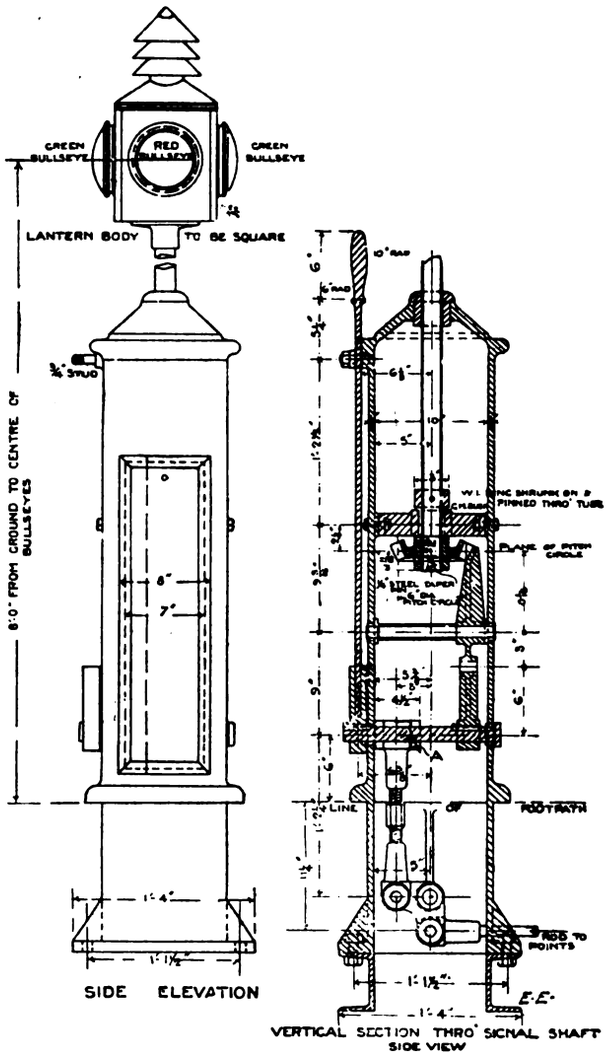

Fig. 19.—Signalling and Point Switchin Box.

place of the old standard with a wooden or fibre insulating gap. The new pattern has a double air-gap in the trolley path, and is far stronger, having two bo[l]+ to carry the strain of the tension in the overhead wire instead of one.

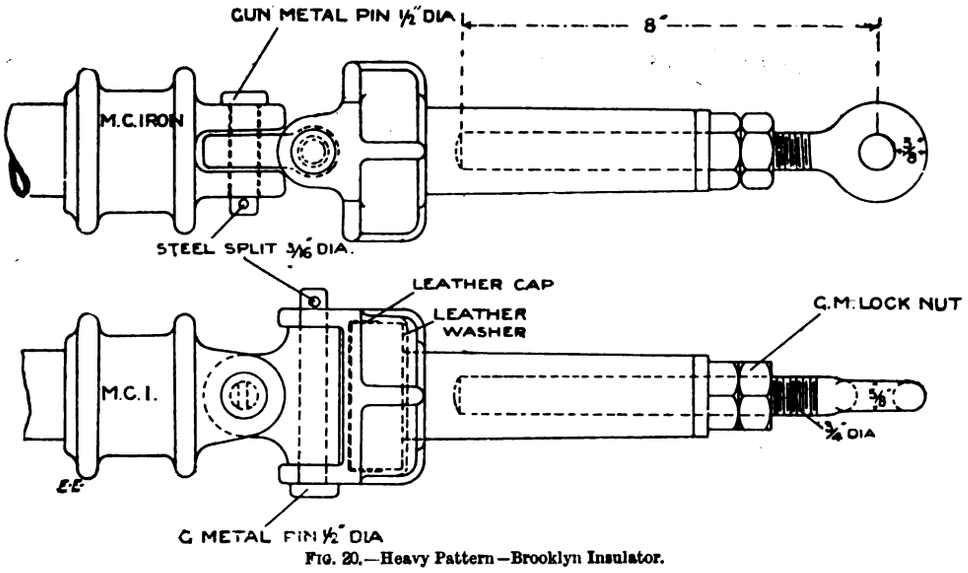

Fig. 20.—Heavy Pattern—Brooklyn Insulator.

The feeders are being rearranged so that they are not connected to either side of the insulating ears of each section, but to a special feeder ear in the centre. This gives the advantage that there is one section switchbox only for

At busy junctions the points are controlled from a signal box on the pavement. This is of cast iron, similar in pattern to a section box, but rising from the top is a four-sided lantern. The action of the lever which works the

Digitized by Google

points also revolves this lantern, and shows a light indicating which route is open. Judging from appearances, the man who works the points in the middle of the road at Westminster Bridge would certainly appreciate one of these signal boxes instead of having to dodge the heavy traffic at that terminus.

At the Richmond Bridge terminus there is an arrangement of the trolley wire which automatically reverses the trolley as the car starts on its return journey. For convenience, only one half of the arrangement is shown in the diagram (Fig. 14). While the car is on the section *a* the trolley pole is in its usual position, and remains so until the trolley head passes the frog, *d*, when the car stops. When the driver starts the car on the return journey, the trolley head runs out over the curve *b* to another frog, which is fixed at such a distance that the trolley pole is at right angles to the car when the head is in this position; as the car continues its journey the head naturally follows the curve *c* back to the line again on the other road. Double the amount of overhead work shown is needed on this line because the trolley standards are not placed in the centre of the car roof, and the exigencies of the track bring the cars up to the terminus with the standards both right and left handed of the centre line, and the locking gear does not allow of a complete revolution of the trolley pole in either direction, which would, of course, break the trolley cable eventually, if allowed, and would certainly strip the insulation.

At Heath-road Bridge, Twickenham, automatic signalling has been adopted over a stretch of single track on which the view is blocked by a railway bridge under which the track dips and which is further complicated by a sharp curve. Referring to the drawing (Fig. 17), A and B are two sections of double track with single track intervening. A car passing along the track enters A, when the trolley head makes contact between the live wire and contact piece No. 1. This sends a current through L_2 and locks the signal at B against any car travelling in the opposite direction; when the contact 2 is reached, both signals are locked at danger, so that no car can follow on to the single track, neither can any car meet the one now on it. When contact 3 is reached both signals are released. The reverse occurs when a car comes from the opposite direction.

All the fittings in original overhead work are being replaced by the heaviest patterns now available, and the new posts are also heavier than usual, because it has been found that any apparently additional outlay on these points really justifies itself on account of the resulting economy in maintenance.

The track rails are the ordinary standard heavy girder rail with bonded joints and flat sole-plates, laid on a bed of concrete in conformity with the usual practice.

In conclusion, I must express my hearty thanks to Mr. J. Clifton Robinson, C.E., the managing director and engineer of the company, and his technical staff, by whose courtesy every facility has been given me in the preparation of this article.

THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

The Parallel Running of Alternators.

BY H. GÖRGES.

(Concluded from page 200.)

Very similar phenomena occur in driving a synchronous motor. A synchronising force is also present in this case, and consequently there is the same tendency for natural oscillations to be set up, these being damped as in the generator. The output of the motor may be subject to periodic fluctuations, but this will be the case only under exceptional circumstances—for instance, if the motor drives shafting to which a steam-engine is also coupled. On the other hand, it will frequently occur that the periodicity of the alternating current conveyed to the motor is not quite constant, but subject to slight periodically varying fluctuations. The motor will then—even if we previously assume that it runs at a uniform speed—possess lead and lag relative to the voltage of the input current. These relative oscillations are increased by resonance, so that we obtain actual mechanical oscillations—that is to say, variations in the speed of the motor. By means of damping, these forced oscillations may again be reduced at will, but only at the cost of uniform input. This brief consideration shows us that the phenomena in connection with a synchronous motor are analogous to those which occur in the case of generators running in parallel. In order to more closely observe the phenomena, we must take the governor of the driving engine into our final consideration. The action of the governor, due chiefly to the great diversity of types in vogue, is so complex in character that it requires a special consideration which it is quite beyond the scope of this paper to give. We must, therefore, content ourselves here with a brief consideration of those points which more especially concern parallel running.

One of the principles on which the steady action of the governor depends consists in that its degree of sensitiveness must be less than the degree of irregularity in the flywheel; in other words, it must not be sufficiently sensitive to respond to the differences in speed corresponding to the irregular acceleration of the piston. But we have seen that in parallel running the degree of irregularity is increased either by the presence of natural oscillations, or more especially by an increase of the forced oscillations due to resonance. In determining the permissible sensitiveness of the governor, the designer can no longer base his calculations on already established rules, but must take into consideration the particular phenomena attending parallel running, and provide for it being greater than the irregularity. If this care be not observed, the limit can be easily exceeded, with consequences which may be illustrated by a simple example. We have seen that at the instant of greatest lead the driving moment and the input of energy are at a minimum, and the output yielded, apart from damping, at a maximum value. This instant, however, is preceded during a half period by too high a speed, which, according to our assumption, will have been responded to by the governor, so that at the commencement of a fresh cycle the input of energy is still further reduced. Let us imagine the case of a Watt type of governor, whose arms are thrown out, due to the increased speed, and which therefore admits less steam at the beginning of a fresh stroke of the piston. If a state of equilibrium was previously upset due to the greatest lead, because the input was less than the output yielded, then the balance will be further disturbed by this decrease, and the return swing made more pronounced. At the instant of greatest lag the minimum output corresponds temporarily with the maximum input of energy and increased supply of steam. It is obvious that the governor must help to increase the oscillations in proportion to its sensitiveness to the changes in speed. If we were to retard the action of the governor for another half-period, then the reduction in the quantity of steam admitted would correspond with the greatest lag, and thereby effect a reduction of the oscillations. By the use of oil dash-pots or other means of damping the movement of the governor we may ensure either that the governor will not respond to the variations in the speed during one revolution, or that it shall help to effect a reduction of the oscillations. Without such provision a constant increase of the oscillations may occur, even if the moving parts be extra massive, and this increase will inevitably cause the machines to fall out of step. But if the generators have damping, then the degree of variation in the speed is not increased to the same extent when running in parallel, as would otherwise be the case. It is therefore possible that damping may be employed with advantage here also, if it is unnecessary in connection with the other oscillations. In this case the damping of the dynamo replaces the damping of the governor.

The oscillation with which we have just dealt may be illustrated by means of a device which I will now briefly describe. This consists of a horizontal shaft driven by means of a driving rod and crank of adjustable length from a shaft mounted under it, and revolving uniformly in its bearings in such a manner that the first shaft is constrained to produce oscillations of a sine-like character about its axis. The amplitude of the oscillations is

Digitized by Google

indicated by a pointer fixed to the shaft. A heavy copper disc running on ball bearings is mounted on the oscillating shaft, being coupled to the latter by means of two watch springs. Now, if the upper shaft be held, then the copper disc will produce natural oscillations directly it is moved from its position of rest. A scale arranged at the periphery of the disc in conjunction with a mark set opposite the zero division of this scale enables the amplitude of the oscillations to be observed. The period of the natural oscillations amounts to about three seconds, so that the number of natural oscillations produced per minute is 20. Now, if we excite the electromagnets between the poles of which the copper disc revolves, then a damping effect will be produced, which may be made stronger or weaker at will by varying the excitation.

The superposition of the oscillations may be clearly seen if we set the upper shaft in quick motion and then give the disc a knock. The forced oscillations are now difficult to distinguish, the natural oscillations ensuing apparently as if the shaft were at rest. The length of oscillation depends upon the strength of the impulse which we give the disc. By means of damping we can eliminate the natural oscillations. There then remain the small forced oscillations, which correspond exactly to the cycle of the oscillating shaft. These forced oscillations are found to have about 180deg. phase distortion relative to the induced oscillations, thus proving the theory to be correct.

The interference between the oscillations is seen better if we decrease the rate of the shaft oscillations. When the apparatus is hand-driven, it is scarcely possible to turn with sufficient uniformity to avoid the continual setting up of natural oscillations. By means of damping we can, however, eliminate these. Let us gradually reduce the oscillations of the shaft when we have slight damping. It will be seen that the copper disc then oscillates exactly in synchronism with the pointer attached rigidly to the shaft, but that its amplitude of oscillation increases as we reduce the speed. By turning so slowly that the oscillations of the shaft become far slower in their succession than the natural oscillations represented by the copper disc, the length of oscillation of the disc will be reduced again until the movement synchronises almost exactly with that of the pointer.

By cutting off the damping we can easily set the disc in such violent oscillation by means of resonance that it will swing more than 180deg. to either side, while the shaft itself swings through only ± 15deg. In this case the oscillations are increased more than twelvefold by resonance. By switching in the damping we can very quickly moderate these oscillations. Indeed, we must resort to this means to prevent the apparatus from injury. If we drive the lower shafts by means of a small motor instead of by hand, so that greater uniformity is obtained in the speed, then the apparatus can also be used for making quantitative measurements. The means of adjustment provided enable the length of the oscillations of the shaft to be varied between 22deg. and 38deg. By regulating the tension of the watch springs, the duration of oscillation may also be adjusted to the required value.

The theory of the oscillations not only gives us an explanation of the behaviour of alternate-current machines when running in parallel, but also governs other important questions. Yet the very existence of alternate currents depends upon oscillations. The insight obtained into the production of the oscillations by studying the question of parallel running is of especial value to us in pursuing the study of the pressure rises which occur in high-tension mains, and is of further use in connection with wireless telegraphy.

TUNBRIDGE WELLS ELECTRICITY ACCOUNTS.

From the accounts of the Tunbridge Wells electricity department for the year ended March 31, 1903, it appears that the total expenditure on capital account to that date amounted to £71,456. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are appended.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Generation of electricity	4,689	3	9
Distribution of electricity	90	3	6
Public lamps—attending and repairs	397	9	10
Rents, rates, and taxes	255	13	3

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s 6d. New Volume, January to July, 1903, now ready.*

EXHIBITIONS.

Has not the time come to discuss seriously the true value of exhibitions? The past is past, and what has been done cannot be undone; but what of the future? Every year or two the Government is coerced into finding fifty or a hundred thousand pounds more or less for the expenses of a commission to some exhibition or other. Does the nation get value for its money? If the exhibitions were in this country, there might be some object in such expenditure, but usually they are held in other countries, which obtain the immediate benefit, if any. What are the advantages put forward, and what are they worth? In the first place, it is said, and with some amount of truth, that exhibitions bring buyers from all parts of the earth to see the latest improvements, and that if our competitors only show, their goods are bought and ours left out in the cold. In other words, exhibitions are held to be a good form of advertising. Granted, but why should the nation at large pay part of the cost of advertising a man's goods? Surely that payment is part and parcel of the manufacturing cost, and should be borne directly by the maker. The main question an exhibitor asks is, Will it pay? and if the answer is in the affirmative, he exhibits; and if in the negative, the fractional assistance he gets from a Government grant will not induce him to do so. The benefit to the individual is the benefit to the country at large; if the one gets a favourable monetary return, so does the other, and *vice versâ*. Of all the howlers for pecuniary assistance, there is none so great as the howling artist who says the country ought to show everywhere the results of its artists' work. What for? To attract shillings to an exhibition the profits of which go into another nation's pockets? Why advertise artists any more than bootblacks? The country has a long purse, and everybody who needs a sovereign thinks the nation ought to provide him with that amount of pocket money. Self-help is no longer a fashionable craze, but begging is. In our opinion, the patronage of exhibitions abroad is a mistake; if you want a big bazaar, have it at home. When have we in recent years obtained any advantage from exhibitions? Their value is in the earlier stages of any industry, not subsequently. France, in 1878 and 1881, did good with exhibitions, and from what was done and seen at Paris the electric era commenced. But we doubt if any such advantage could accrue to the industry again. Exhibitions now do not enlighten; they are merely salesrooms. We know the best and worst that can be exhibited. Government expenditure, if these conclusions are correct, is unwarranted. The thing assisted is not educational, but merely financial, and the direct payments should be made by those who get the direct receipts. This brings another question. Is it of advantage to have a perambulating sample and salesroom? Undoubtedly, yes, for certain manufacturers, these differing according to locality and circumstance. But the Government funds ought not to provide a travelling showroom, any more than it provides a traveller with samples. The latter is just as much a perambulating showroom as an exhibition annexe—no more, no less; yet manufacturers do not come to the Government for financial aid in sending out travellers. All this preliminary is intended to show that exhibitions at the present stage of the world's history are merely money-making concerns, and to argue if that is so, our Government at any rate can better spend its money in some other direction—preferably by leaving it in the pockets of the taxpayers. Everywhere, municipally and Governmentally, the energy and business capacity of the individual is being ignored, and restrictions

Digitized by Google

of all kinds are cropping up like autumn leaves in Vallombrosa.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE ELECTRIC TUNNEL DANGER.

SIR,—An article in the *Daily Mail* of the 13th inst. gives the details of an interview with Mr. Yerkes, in which he is reported to have said that "it is absurd to talk about covering cables with asbestos and other non-flammable material, as when a wire breaks the current forms an arc, which destroys asbestos as readily as wood." The moral of the article is a good one: that non-flammable wood and fittings should be used on electric trams wherever possible, but the statement regarding the universal inflammability of electric cables is not strictly correct.

As Mr. Yerkes is recognised as an authority in electric railway affairs, may we point out that we make a patent cable which will not take fire, and have used same in pit work extensively, and also upon the rolling-stock of a tunnel electric railway, it being specially examined and passed by the Board of Trade for this purpose.

We agree with Mr. Yerkes that asbestos should not be relied upon. The materials we use are jute and hemp rendered non-flammable by special chemical treatment. This can be applied as an outer cover to any type of cable.

For heavy usage, such as trailing cables, we braid over all with leather strip, and this arrangement has been highly approved of by colliery experts as the safest type in use.

Where such non-flammable cable is used, although an arc may momentarily occur under specially advantageous conditions, there would be no chance of the cable covering itself taking fire, as the *material will not burn*.

We are quite willing to submit this class of cable to any tests that interested persons may desire.—Yours, etc.,

W. T. GLOVER AND CO., LIMITED.

WIRELESS FIRE-ALARMS.

SIR,—I have read the comments you have made after my letter published in your last week's issue, and would say that the condensation of my letter fairly represents my ideas. I note with pleasure that you implicitly admit (1) that wireless telegraphy furnishes the best, and perhaps the only, solution of the conditions printed by the Fire Prevention Congress of London for automatically warning and directing fire stations; (2) that there is not much need to fear that any two fire-alarms will act simultaneously. Concerning the opinion you express in your last paragraph, I consider it quite unjustifiable, because it is impossible to construct an automatic fire-alarm which will not give a false alarm when necessary precautions are taken in the design of the apparatus. In the same way, the authorities in London condemn, generally in a too absolute way, all automatic apparatus without giving the inventors the opportunity of refuting their objections. In short, the question is reduced to the following dilemma. Either it is necessary to use automatic alarms, in which case the fire brigade might be exposed to false alarms; or it is necessary to use fire-alarms which are not automatic, in which case the brigade may be called too late for useful service. It seems to me that the first choice is the better. You say finally: "He does not realise our point that his wireless fire-alarm station would be receiving at odd times Morse code messages from other wireless telegraph systems in the neighbourhood, or from casual experimenters." This seems to me to be so easily avoided that I had hardly thought it necessary to consider the case. If it was not that the apparatus ought to be very simple, I could give a dozen remedies. I will confine myself to two simple ways which are applicable to prevent interference in wireless telegraphy generally. The first is to so arrange the automatic Morse that it will only be unlocked if the telegram is preceded by a certain signal—a very long dash, for example. This will avoid false alarms, but will not avoid trouble during the transmission of the actual signal. The second way is to so regulate the receiver that it would only respond to signals longer than of a certain length—*i.e.*, longer than the ordinary signals. This result can be obtained without any trouble by mechanical means. Again, syntonisation for small distances will largely avoid the danger which you point out.—Yours, etc.,

E. GUARINI.

[We have read the above letter with interest, and are pleased to see Mr. Guarini so hopeful in overcoming the trouble of interference, which still seems to us to be a very real one. As they say, "the proof of the pudding is in the eating," and we await with interest the practical trial on commercial lines of a wireless fire-alarm system. We can only add that we are far from this admission credited to us above, and have yet to be convinced that such a system is advisable or practical.—ED. *E. E.*]

THE SLOT-CONDUIT SYSTEM AND THE SCHUCKERT SURFACE-CONTACT SYSTEM.

Here in England, especially in London, where the question of a system for the electric tramways is at present much in discussion, it is of extreme importance to obtain some particulars regarding the revenue-earning capacity of systems other than the overhead trolley, which is greatly objected to on account of the heavy street traffic.

At the International Tramways and Light Railways Association Congress held at the Agricultural Hall in July, 1902, reports on the experience obtained with various traction systems came up for discussion. Unfortunately time did not permit the question to be adequately discussed, and one had to be satisfied merely with the remarks of Mr. Ziffer, the gentleman chosen to read the paper on underground current supply systems, who referred in particular to the slot-conduit system in Paris and Brussels, and the surface-contact systems of Claret and Vuilleumier, Générale Electric Company Monaco, Diatto, Lorain Steel Company, Kingsland, and Schuckert. The last-named system was worked for two years in Münich in the regular tramway service, after having been examined and tested by the special experts appointed by the Bavarian Government and the Münich Municipality. It had, however, at the time of the congress, already been substantially modified, continuous efforts having been made to further develop it in all its details, so as to enable it to fulfil all working requirements and the other customary conditions laid down for such a traction system.

The system in its present design has attained so high a degree of safety that it is in this, as well as in other respects, a great improvement on the slot-conduit system. It may be mentioned that during the whole period of working of the Schuckert surface-contact system in Münich no single accident occurred, whilst there were eight wire breakages on the overhead trolley. Although the surface-contact section was admittedly very much shorter than the lines equipped on the trolley, yet the fact as stated above is an interesting commentary on the relative safety of the two systems. The only system which offers anything like the same safety for public traffic is the slot-conduit system, but the cost of installation and maintenance is so enormous that only towns having extraordinarily heavy traffic are able to introduce it. Even then towns such as Berlin and Vienna, which have for some time had the slot system in operation, are desirous of abandoning this method of working, as in consequence of the heavy working expenses and the repeated interruptions to traffic, the causes of which are always the same, the slot-conduit system can scarcely lay claim to reliability and economy.

Despite the fact that slot-conduit systems have been for nearly 14 years in service (Budapest) there is very little information available as to the cost of installation and working, and even the statements in the returns issued by the various undertakings differ very substantially. We consider it, however, desirable to utilise those particulars which were furnished by the tramway departments of Brussels and Paris and submitted at the International Tramway Congress, and we furnish herewith as far as possible a statement of working expenses in order to

Digitized by Google

compare these with the expense of working the Schuckert surface-contact system.

BRUSSELS SYSTEM.

The Brussels tramway has 6·21 miles double track—*i.e.*, 12·42 miles of the slot-conduit system in operation—and the present lines have been in operation since May and November, 1897. For the maintenance of the slot-conduit system the following staff is required: one track superintendent for the continual examination of insulators, conductors, connections, etc.; four track inspectors; six conduit cleaners to clean out dirt, and from time to time, say every two or three months according to requirements, wash the insulators with water, etc.

In addition, the paving adjacent to the conduit sections entails very considerable cost of maintenance. Another expense in the maintenance arises from the necessity of regulating at special times the distance of the two rails which form the slot. Difficulties are caused in cold weather by the swelling of the pavement and the resultant narrowing of the slot.

The maintenance of the rolling-stock on slot-conduit systems consist mainly in renewing the contact ploughs. This last-named item in the maintenance varies very much, depending largely on the care and attention of the car driver. The cost of the maintenance is reduced by offering the drivers an annual premium provided no contact ploughs are injured. The mistake most frequently made by the drivers is the omission to raise the contact ploughs at the line terminus, thereby allowing them to foul the points. A special item of expense incurred in working the slot-conduit system is the cost of keeping pointsmen at all the junctions which are used in regular service by the cars. As the junctions on a slot-conduit system must be locked, they have to be moved according to the direction in which the car is travelling. The consequences of an incorrect position of the points are so serious, that one cannot leave their manipulation in the hands of drivers or conductors. This is specially the case on lines with heavy traffic. In order to obtain a comprehensive idea as to the working expenses, the following particulars and cost of working a slot-conduit system in comparison with the Schuckert surface-contact system are furnished.

The report of the Brussels tramway did not contain all figures requisite for the preparation of a statement of the working expenses, etc. For instance, in the report the cost of installation of the 6·21 miles (10 km.) double track is given at "£78,430"; but the cost of paving, trenching, and other work in connection with the displacement of the existing water and gas mains, drains, and electric light and telephone wires, etc., is stated at "£2,350 extra per car in service," without mention of the number of cars employed.

The cost for working the points is given at "0·378d. per car mile," but no data is given as to the actual number of car miles run.

In order to ascertain what these important additions to initial cost and working expenses amount to, we will assume that with an 18 hours' service 33 cars run 1,631,988 miles per annum. (This is not too high an estimate, considering the traffic conditions on the line in Brussels.) We thus find that the extra cost incurred in the installation of the slot conduit, owing to the shifting of pipes, etc., in the roadway, amounted to

$$33 \times £2{,}350 = £77{,}550.$$

The cost of working the points amounts to

$$1{,}631{,}988 \times 0{\cdot}378\text{d.} = £2{,}570 \text{ per annum.}$$

Furthermore, assuming the wages of the track superintendent mentioned above at 6s. per day, the four inspectors at each 4s., and the six cleaners at each 3s. 6d., we find that the cost of cleaning the conduit alone costs per annum £821.

The working costs of any system should cover the interest on capital, payment to the sinking fund, and in this case there must be added the cost of cleaning the conduit, and, further, the cost of point shifting.

The total cost of installation, therefore, amounted to

$$£78{,}430 + £77{,}550 = £155{,}980.$$

Comparing this with the cost of installation of a line of same length on the Schuckert surface-contact system under similar conditions in Brussels—viz., £70,588—we find that the conduit system necessitated an additional expenditure of £85,392. The annual charge for interest (4 per cent.) and sinking fund (assuming 21 years) on this sum amounts to £6,086; to this add cost of working points, £2,570, and cost of cleaning the slot conduit, £821, and we have an annual extra cost of working of £9,477 for the 6·21 miles, or £1,526 per mile of double track more than with the Schuckert surface-contact system, inasmuch as the costs for cleaning the conduit and for shifting the points are not incurred with the Schuckert system, and, furthermore, there is no extra expenditure necessary for the shifting of gas or water pipes, etc., as no greater depth of road surface is occupied than necessary for laying the rails.

PARIS SYSTEM.

The Compagnie Générale Parisienne de Tramway, Paris, works municipal lines which are also constructed on the slot-conduit system. This system is employed on three different lines having a total length of 6·52 miles double track—*i.e.*, 13·04 miles conduit. The working expenses of this plant are composed in a similar way to those of the Brussels tramway. The maintenance of the conduit and the accessory parts had up to the time of the report to the International Congress consisted of the replacing of some insulators for the conductor bars and the adjustment of the width of the slot in several places where, owing to the pressure of the wooden pavement, it had become too narrow. The maintenance of the track would probably be about the same as for an ordinary tramway track, but the cost of cleaning the conduit has to be added.

It is also stated in the report that the points of the slot conduit system are far more complicated and susceptible than those of an ordinary tramway line. It is, therefore, necessary to pay special attention to this point, and to employ for the duties of point shifting properly experienced pointsmen at comparatively high wages. It is of interest to have had confirmed that breakdowns have been experienced owing to the points not having been properly shifted, as a consequence of which the plough has been pushed into another track and smashed. The same defects which at once came to light on the first lines equipped on the conduit system, and resulted in interruptions to traffic, have not yet been overcome on the newer and more recently installed lines. When accidents happen with the conduit system the consequences are much more serious, on account of the interruption to traffic. This is especially the case, as there is the danger of the contact plough breaking or sticking in the slot, and should such an accident occur the respective car is brought to a standstill, together with all following cars, the whole service being delayed during the time which the removal of the contact plough requires. With the surface-contact system, however, it is always possible to have any car which is accidentally injured pushed forward by the car following immediately behind it. So far as the maintenance of the rolling-stock is concerned, only the wear of the contact plough has to be taken into account. Such a plough is far more expensive than the trolley wheels, but as it is stated that the life of the former is much longer (about 10,000 car miles), the costs per car mile should be in both cases about the same. The cost for renewing the linked chain skate used in the Schuckert system works out at approximately the same per car mile. A further increase of the working costs will be caused by dividing up the feeders into sections of about 1,000m. to 1,500m. This is necessary in order to be able to switch over the different sections of the line, so as to as far as possible avoid disturbances and breakdowns in case the insulation has become faulty. It is claimed that the current losses are so small that under the worst working conditions they will scarcely exceed a few amperes for the entire system. It must, however, be again pointed out that current losses depend directly on the attention paid to the maintenance of the entire plant—that is to say, these losses vary according to the state of the insulation at any time. The insulation of the underground conductor is, in consequence of the climatic conditions,

Digitized by Google

subjected to considerable variations, and it is necessary to wash from time to time the insulators in the conduit if heavy current losses are to be avoided. It is therefore safe to maintain that the construction of the slot-conduit system in no wise excludes, as often erroneously assumed, the possibility of current leakages.

In order to ascertain the revenue-earning capacity of the Paris slot-conduit system, it is necessary to make an assumption with regard to the car mileage, as also in this case exact figures are not given in the official returns. We will, therefore, in order to make a comparison with the surface-contact system, assume for the purpose of calculation the same figures as for Brussels—viz., 1,631,988 car miles with 33 cars running 18 hours per day. The length of the line is 6·52 miles double track—*i.e.*, 13·12 miles conduit.

For the construction of 13·04 miles single track the cost of installation works out at "about £218,235," including earthwork and paving, the construction of the slot conduit, the track laying, connection to the drains, displacement of gas and water mains lying in the path of the conduit. The expenses for cleaning the conduit of the entire line per year are given at "£1,729." The costs for controlling the points per year are not given, and we will, therefore, assume the same figures as for Brussels—viz., £2,570.

The cost of installing the Schuckert surface-contact system on a line of same length under similar conditions in Paris would not be more than £75,660. Deducting this sum from the cost of the slot-conduit system—£218,235—we find that the latter has cost £142,575 more. Interest at 4 per cent. and sinking fund spread over 21 years will require on the extra cost of installation £10,162 per annum. Adding to this cost of cleaning conduit, "£1,729," and cost of controlling switch points, £2,570, we find that the 6·52 miles of double track costs £14,461 per annum—*i.e.*, £2,217 per mile double track—more than the Schuckert system. With this latter system there would also be a considerable saving in working expenses in consequence of the smaller sum required for interest and redemption of the initial outlay, and no charges for cleaning the conduit, adjusting the points, and shifting the telephone wires and gas and water pipes.

As a matter of fact the working expenses of the slot-conduit system will be, indeed, very substantially higher, as one must allow a certain percentage for the current losses on the conduit system, if great care is not taken to clean the insulators in the conduit at frequent intervals, and to keep the whole system throughout in perfect order.

The switchboard plant in the central station and the complete installation of a slot-conduit system involves a substantially greater expense, inasmuch, as already reported by the Compagnie Générale de Parisienne, the conduit line is divided into sections of 1,000-1,500m., and each of these sections is connected by separate feeding cables with the switchboard installation.

This should be sufficient to prove the correctness of the general assumption that the cost of working a slot-conduit system is substantially higher than that involved in working the overhead system. If the Brussels Tramway Company, in answering the enquiry sheet for the twelfth general meeting of the International Tramway Association, states: "Although generally speaking, the cost of installation of the slot-conduit system is much more expensive than that of the overhead-wire system, yet the difference in working expenses is not very considerable," then it is not taken into consideration that the working cost is made up of the interest and sinking fund charges on the cost of installation plus the cost of maintenance of the entire plant, and the cost of pointsmen and conduit cleaners are forgotten. The cost of maintenance is also substantially higher than that of the Schuckert surface-contact system, as will be perceived from the above figures. That it is higher than on lines equipped with the overhead system is proved by the returns of the various undertakings.

In comparison with all other existing systems, the Schuckert surface-contact system has with the overhead system the lowest working charges, and it has been proved by practical experience that the Schuckert system in its present form does not require higher maintenance charges than the overhead system. The cost of installation is very much lower than that of the slot-conduit system, and is, as compared with it, not so high that a line so equipped would only pay with extremely heavy traffic. The Schuckert system can, therefore, on account of its safe and efficient working, claim to be adapted to replace the overhead system in all streets in which the conditions of heavy traffic do not allow of the adoption of the overhead system.

The great objections often brought forward against the introduction of a surface-contact system are entirely set aside by the results obtained with the Schuckert system in practical working, and it can safely be claimed that this system, in comparison with all others, possesses the following advantages:

1. Higher guarantees for safe and regular working than any other system.
2. Simple and rapid track installation without inconvenience to ordinary traffic.
3. Better insulation, and consequently lower current consumption, than with any other system.
4. Facility of adopting any existing standard car for the surface-contact system.
5. Ease with which cars can be made to travel in either direction without necessitating the driver leaving the car for switching over the apparatus.
6. Convenience for use with combined systems, where the overhead trolley is used on the outlying portions of the town and underground supply within the town area, the only necessity being to replace the trolley pole when passing to the overhead sections.
7. No possibility of danger from live studs, as the switches are interconnected in such a way that the same current which closes the switch to a stud over which the car has just arrived forcibly opens the switch of a corresponding stud which the car is just leaving; this latter stud being rendered inactive before it is exposed. In the exceptional case of this action failing, three different and independent safety devices come into operation to cut off the current supply on the 100 yards section on which the car happens to be situated.
8. All working parts easily accessible for inspection and localisation of faults.
9. Cost of maintenance not more than that of the overhead trolley system.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

611. Two 300-kw. alternators running in parallel and fully loaded, when a short-circuit occurs on one of the high-tension feeders. After the feeder being made dead, the two machines are put in parallel again on the 'bus bars (with no load). Would it be safe to switch in the remaining (say six) feeders one by one?—P. C. S.

612. Are shunt motors of the same brake horse-power ever wound to give different starting torques? If so, what is the practical maximum torque per brake horse-power in pounds-feet that can be obtained?—F. E. H.

ANSWERS.

Question No. 603.—Why do some firms use star and mesh starting switch on squirrel-cage three-phase motors, and does star coupling increase the torque and reduce the current taken for a given starting torque, or is the torque greater when mesh coupled, the turns per phase being the same in each case?

Digitized by Google

Best Answer to No. 603 (*awarded* 10*s.*).—Star and mesh starting switches are usually employed for increasing the starting torque, the motor being normally star coupled and being changed to mesh whilst starting. This has the effect of increasing the volts per phase (A to B, Figs. 1 and 2) at starting in the ratio of 1 : 1·73, and since the maximum starting torque varies approximately as the square of the volts per phase, this torque is increased in the ratio of 1 : $(1{\cdot}73)^2$ or 1 : 3.

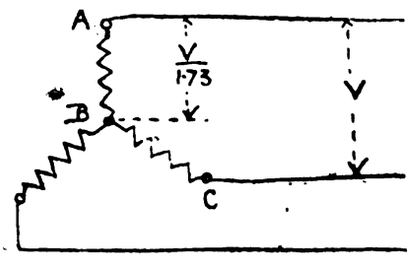

FIG. 1.

Occasionally, however, in the case of motors intended to start at light load the above connections are reversed, the normal condition being the mesh connection, and this being changed to the star connection for starting. This has the same effect as reducing the volts per phase by an auto-transformer, and reduces the initial rush of current when starting up light, though at the same time it reduces the starting torque and the motor requires a longer time to reach full speed.

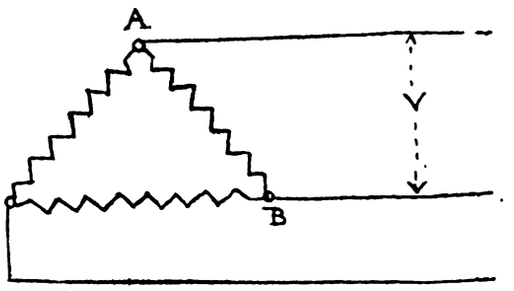

FIG. 2.

With regard to the latter part of the question, if by the "turns per phase" the number of turns between A and B in Figs. 1 and 2 is meant, the star connection will give a lower maximum starting torque per ampere taken from the line than the mesh connection in the ratio of 1 : 1·73. If, however, the total turns from A to C in Fig. 1 are equal to the turns from A to B in Fig. 2, the star connection would give the same torque per ampere taken from the line as the mesh connection. In all cases the maximum starting torque depends on the volts per turn of winding—*i.e.*, the flux—as well as the total turns per phase, but not directly on the method of connection, whether mesh or star. The latter is, however, more commonly employed, as it prevents the possibility of idle currents circulating in the windings.—Q.

Answer to No. 603 (*awarded* 7*s.* 6*d.*).—The "star" connection of the coils of a three-phase motor offers advantages to the manufacturer over the "delta" or mesh grouping. With the latter arrangement of the coils the voltage per phase is equal to the voltage between the line wires, while with the Y grouping the voltage per phase is equal to the line voltage divided by $\sqrt{3}$ (= 1·732). The constructional advantages secured by the adoption of the Y grouping will be apparent (especially in high-voltage machines) when consideration is given to the insulation of the conductors and section of iron required for the stator. An example will best serve to bring out this last point: three-phase motor, 150 h.p, 600 revolutions per minute, 550 volts, eight poles, 40 periods per second. The voltage per phase with Δ connection of the stator will be 550 volts, and with Y connection will be $\frac{550}{\sqrt{3}}$ = 320 volts. For the purposes of this example we will assume the same drop in the winding for each case—viz., 20 volts. Hence the back E.M.F. to be generated in the stator coils is 530 volts for the Δ and 300 volts for the Y grouping. We will consider the same number of turns in series per phase in each case—viz., 80. A convenient formula for the flux to be produced in the stator in order to generate the requisite back E.M.F. is the following*:

$$M = \frac{E \times 10^8}{4{\cdot}44\ T\ N},$$

where E is the effective E.M.F. generated in volts;
T the number of turns in series per phase;
N the number of magnetic cycles per second (equal to the periodicity); and
M the number of C.G.S. lines *simultaneously* linked with the T turns.

Inserting the above values for these terms, we get for the Y grouping $M = \frac{300 \times 10^8}{4{\cdot}44 \times 80 \times 40} = 2{\cdot}15$ megalines, and for the Δ grouping $M = \frac{530 \times 10^8}{4{\cdot}44 \times 80 \times 40} = 3{\cdot}72$ megalines. Considering the fact that the magnetic circuit of an induction motor is worked at a low density—about 40 kilolines per square inch—it will be evident that the Y grouping offers advantages to the manufacturer, notwithstanding that the current in the conductors is $\sqrt{3}$ greater than that with the Δ grouping. If, however, a large starting torque is required, the Δ grouping should be adopted. This will readily be seen from the following formula for the torque:

$$T = s\,.\,B_m{}^2\,K,$$

where T is the torque in pounds-feet;
s the slip;
B_m the maximum value of the flux density in the air-gap; and
K a constant depending on the mechanical construction of the motor.

Now, for the same slip the torque is proportional to $B_m{}^2$, and B_m is proportional to the total flux in the stator. The total flux, as will be seen on reference to the first equation, is proportional to E—the voltage per phase of the stator winding. This depends on the grouping, and hence for the same turns per phase the torque will be about 75 per cent. greater when the stator coils are connected Δ fashion than when they are connected in Y, other things, of course, remaining the same.

Advantage is taken of this fact in polyphase electric railways for giving a good starting torque. The ends of the stator coils are brought out to a special switch, which is arranged so that at starting the stator coils are Δ connected, and as soon as the car is under weigh, the switch is thrown over, connecting the stator coils in Y fashion. This arrangement for temporarily increasing the torque of a three-phase motor is much advocated by Mr. C. E. L. Brown, and is adopted by the firm of Brown, Boveri, and Co. on their polyphase mountain railways.

For the same horse-power output the current in the conductors with the Y grouping will be $\sqrt{3}$ times greater than that with the Δ grouping. The line current in each case will be the same as that in the conductors when the Δ grouping is employed. It will now be apparent that for high-voltage machines it is advantageous for the manufacturer to adopt the Y grouping, while for low voltages it is more economical to substitute the Δ grouping. In the former case a saving of iron is effected, and in the latter a saving in copper. In the above comparison between the two methods an ordinary case is taken, in which only a normal starting torque is required; special cases, in which a very great starting torque is required, would, of course, be met by the adoption of the Δ grouping.—A. D.

Answer to No. 603 (*awarded* 5*s.*).—There are comparatively few firms who have installed motors which are so arranged, the reason being that the conditions which demand the arrangement are very infrequent. The writer has installed motors so arranged in works where starting apparatus, whether auto-transformer or rheostat, would be inadmissible by reason of the unsuitable environment or rough class of labour. Consulting engineers and their

* This formula is due to Mr. H. F. Parshall. (See "Electric Generators," by Parshall and Hobart, p. 80.)

Digitized by Google

clients sometimes object to any form of starter for three-phase motors in such places as foundries and chemical works, where the labour is frequently of a very rough class, and anything which can be damaged is generally the object of the workman's unremitting attention.

The disadvantages of switching a three-phase motor with a squirrel-cage rotor directly on to the mains, even when the load is comparatively small, are sufficiently well known. To obviate these, the motor, instead of having its three windings connected permanently in star or mesh, has the ends of each phase brought out to two terminals, consequently the motor has six instead of three terminals. These are connected to a simple rotary or change-over switch, in one position of which the three inner ends of the phases are connected together, thus forming the middle of the star. In the next position (the running position) the ends are connected in mesh, the proceeding being obviously a simple one. A motor of this kind is invariably switched into circuit with the coils in star connection. If it is wound to operate at the usual line pressure in mesh connection, as it should be, it will, in star connection, present $\sqrt{3}$ times the impedance to the passage of the current, as the turns across each line wire have been increased in this proportion; therefore, the initial current, which might reach three to five times the full-load amperes, is reduced to from 1·73 to 2·9 times the full-load current, a figure which is not objectionable with small motors. Of course, if the motor has any considerable work to do in starting it will take longer to accelerate when started as above, as the current per pole and phase has been reduced, and, therefore, also the torque (roughly as the square of the stator current), hence small reductions in the stator current have a very prejudicial influence on the starting torque, and the system is only employed when the motors are used to drive shafting or light machinery. Considering the advantages of starting induction motors by other methods, the star mesh system is only likely to be employed under the unusual conditions already indicated.—ELECTRA.

Answer to No. 603 (*awarded* 5*s.*).—The reason why a star and mesh starting switch is sometimes used with a squirrel-cage three-phase motors is that by starting the motor with the windings star connected a greatly reduced current is taken from the mains than with the normal or mesh connection. The starting torque is also correspondingly reduced, and in the same ratio as the current. In other words, the starting torque per ampere remains the same whether a star or mesh coupling be used. This can most readily be seen by taking a concrete case. Let us consider a three-phase motor wound for 200 volts, and having a stationary impedance of, say, five ohms per winding. Suppose the stator is normally connected "mesh" when running, and that it is thrown direct on to the mains.

The current per winding at starting will be $200 \div 5 = 48$ amperes, and that taken from the mains $\sqrt{3} \times 40 = 69{\cdot}3$ amperes. The torque will be proportional to the square of the current in the windings, and for comparative purposes we may call the toque $40^2 = 1{,}600$. The torque per ampere will be $1{,}600 \div 69{\cdot}3 = 23{\cdot}1$.

Now, taking the case of the same motor star connected, we find the voltage on each winding to be $200 \div \sqrt{3} = 115{\cdot}5$ volts. The current per phase is $115{\cdot}5 \div 5 = 23{\cdot}1$ amperes, which is also the line current. The torque is therefore represented by $23{\cdot}1^2 = 533$, and the torque per ampere 23·1. From these figures it may be seen that starting with the windings in star reduces the starting current and torque to one-third, but gives the same torque per ampere input. Starting the motor in this way gives the same values of torque and current as starting with an auto-transformer or compensator having a ratio of $\sqrt{3}$ to 1. Starting with a choking coil or resistance in series with the motor would not be so advantageous, as the torque would decrease with the square of the current taken from the mains.—R. C.

Question No. 604.—Describe how the two motors on an electric tramcar are connected up when braking with rheostatic brake, giving sketch showing path of current.

Best Answer to No. 604 (*awarded* 10*s.*).—The principle upon which a brake of the type specified in the question acts is that which involves the conversion of the motors into generators, and this idea has been the means of introducing a number of electromagnetic devices which are most effective as braking appliances. There are several essential arrangements which must be made in the application of such a brake before that brake can be used to advantage. In the first place, all connection with the source of supply must be broken—that is, the motor equipment must be isolated from the system—otherwise no braking effect could be obtained by the motors; also, the field windings of the motors must be reversed. For since the current generated by a series motor driven as a generator is opposite in direction to that current which must

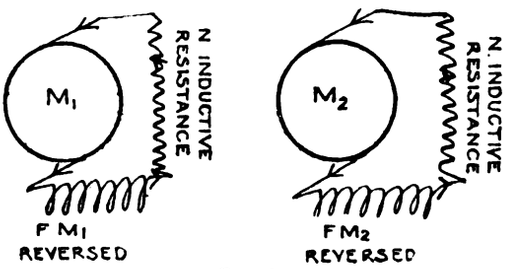

FIG. 1.

be supplied to the series motor to drive it as a motor in the same direction, therefore if the field windings are not reversed, the result will be that the first effect of generation will be to oppose the residual magnetism in the field magnets and then reduce it to zero. And when once that position is attained, it cannot be altered until the supply is brought into requisition again. In a two-motor equipment either the motors can act independently as generators, sending a current through a resistance, or either they can both be connected up together and act jointly as generators.

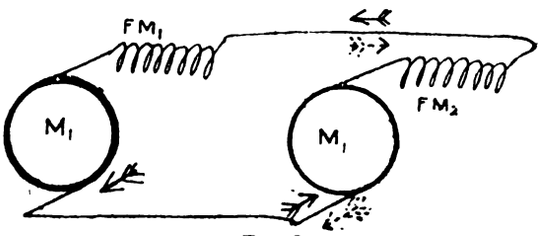

FIG. 2.

Fig. 1 is a diagram of the connections where both motors are connected separately with resistance in circuit. This resistance is gradually taken out until practically the motors are short-circuited, with only their individual armatures and field windings in circuit; and by this means only the brake is sometimes actuated and applied. Another method is that of continuing the above method and connecting the two machines together in parallel. As such each acts as a generator and generates an E.M.F., and on closing the circuit these two distinct voltages oppose each other, and if they were equal would annul each other.

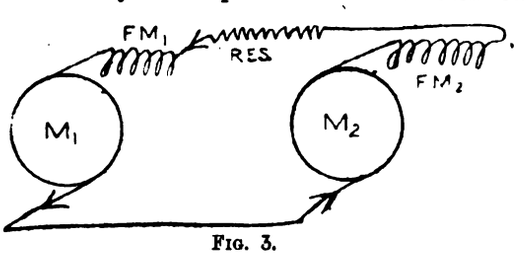

FIG. 3.

This point of equality is never desired, for no braking effect could be obtained with such a state. Such a condition is never obtained in practice Either the permeability of the field magnets of the two motors varies, or else there is some other slight difference in the construction of the motors. In Fig. 2 we have the connections of such an arrangement. The tendency of currents due to the separate and opposite E.M.F. is shown by the full arrow head and the dotted arrow head. The stronger E.M.F. overcomes the weaker one, however, and reverses its field. This reversion in the field produces a likewise reversion in the direction of the current generated by that

Digitized by Google

machine, and this current then increases the current flowing through the whole circuit, which is shown by the full arrow head. The motors are now in series, and as such help each, with the result that, with only the field windings and armatures of the two motors in circuit, an enormous current traverses that circuit, and produces a good braking action. And this current is maintained until the momentum of the car is checked.

Fig. 3 shows the arrangement of connecting the motors together directly in series, and with resistance in circuit. In this case the direction of the currents generated by the respective machines are the same on the first application of the brake. With a resistance in circuit, however, the current does not rise immediately to a great value. But the current is gradually increased by cutting the resistance out, and with all of it out, the case is identical with the second of the above cases.

The current generated in either of the above cases can, whilst producing a braking effect in the armature of the motor, be used in the braking appliances. These may be either magnetic track brakes, disc brakes, or Foucault current brakes, which are all energised by the current generated by the motors.—G. W. B.

Answer to No. 604 (*awarded 7s. 6d.*).—The controller of a tramcar using electric brakes is arranged so that by moving the handle from zero in one direction supplies the motors with energy from the trolley wire, and moving it from zero in the other direction disconnects the motors from the line and short-circuits the motors through a graduated resistance and generally also through an electro-magnetic brake. One type of magnetic brake consists of two cast-iron discs, one of which is fixed to the motor and has a coil of wire wrapped round it, the other is keyed on the axle. The braking action is due to three causes: (1) car is driving the motors as generators and thus doing work, the amount of which can be varied by adjusting the external resistance in motor circuit, and thus the speed of the car is retarded to a greater or less extent; (2) the magnet brake discs are brought into close contact with the axle discs, and resultant friction diminishes the speed of the car; (3) eddy currents are set up in the brake discs as they revolve in the intense magnetic field of the magnet brake discs, and these cause speed to be retarded.

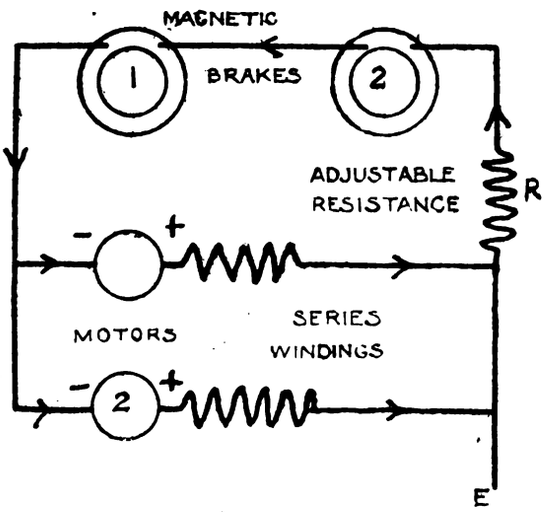

FIG. 1.

The path of the current generated by the two motors when driven by the impetus of the car is clearly shown in Fig. 1. When the electric brake is used, the controller handle must be moved to the first notch of the adjustable resistance, R. The motors start generating current and the speed of the car is retarded. This causes the current generated to drop, and the controller handle is made to cut out more resistance. This brings up the current again, and the speed is again retarded and so on. There is never any need to reverse the motors on a car having electric brakes, as the car can be stopped as quick or quicker than reversing, and without the severe strains thrown on motors and gearing by reversing.

It has been found in practice, that even with electric brakes skidding of car wheels may take place if the full current from the motors were free to flow through magnet discs, as the first flow of current is far in excess of that necessary to stop wheels, and the surplus only heats the motors. To overcome this difficulty, an arrangement known as a "limit switch" has been provided, which consists of a solenoid in series with brake discs, this raising an iron core attached to the switch and causing it to make connection with earth. The connections are shown in Fig. 2. The brake is applied by switching on to the

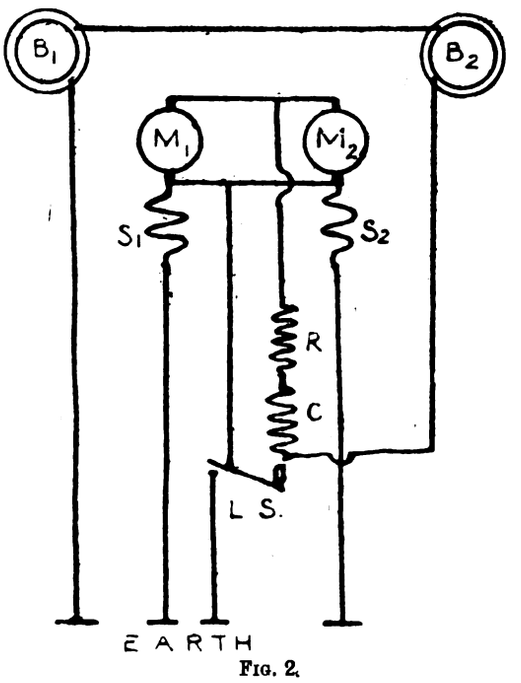

FIG. 2.

first notch of adjustable resistance, R, a current is generated by the motors, M_1 and M_2, which passes through the series windings, S_1 S_2, to rails, then to brakes, B_1 B_2, through solenoid, C, and resistance, R, back to motors. The limit switch, L S, acts against a tension spring, which can be adjusted so that the switch will short-circuit the series windings, thus stopping the current at a point that will prevent the car wheels skidding. Under average track conditions and with ordinary tramcar the switch should be adjusted to act when the current reaches between 30 and 35 amperes. By this means skidding is avoided, and, therefore, flats are not made on the car wheels, and also undue heating and straining of the motors does not take place (Fig. 2).

The metal of which the brake discs are made must be very hard, or excessive wearing takes place. Owing to the hardness of the metal, the discs were found to stick together after the current was taken off, this being due to residual magnetism. This was a disadvantage, as more current was taken to start the car in order to overcome the sticking of the brakes. This difficulty has been overcome by connecting the brake circuit through a resistance in shunt with the first running position of the controller, by which means a weak current is sent through the brake magnets as soon as the handle is moved to start the car. The shunted current flows in the reverse direction to that sent round the magnet coils by the motors, and overcomes any residual magnetism that may be present in the discs.

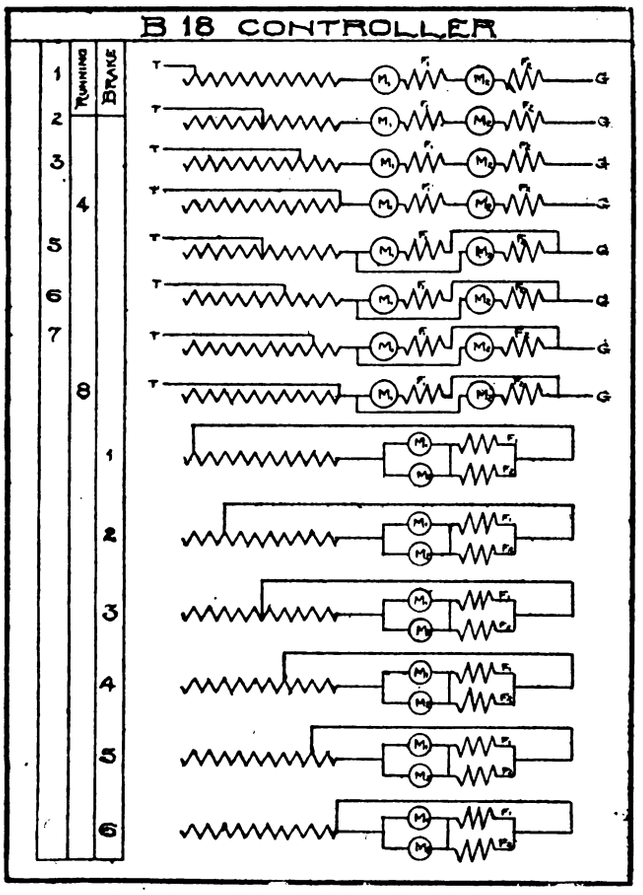
The electric brake is intended for all service stops, as well as emergency stops, but will not hold the car stationary on an incline. The hand-brakes must be applied for this purpose.

I am indebted for the details of the limit switch to a paper read by Mr. Baylor before the Institution some time ago.—W. A. T.

Answer to No. 604 (*awarded 7s. 6d.*).—There are numerous advantages attending the use of the rheostatic brake on electric tramcars, which may be briefly summarised as follows: the application of the brake requires no exertion of the motorman; the brake is automatic, as far as "skidding" of the wheels is concerned, for if the latter

Digitized by Google

"skid" the brake ceases to act, provided, of course, that they are not locked by the hand-brake; the motorman can bring the full braking force into operation in a very short space of time, thereby being of great service in cases of emergency. The controllers for use with the rheostatic electric brake are very similar to the standard controllers for a two-motor equipment without brake. The "power" notches are exactly the same, but there are some additional notches after the controller has been thrown into the "off" position. These additional notches constitute the rheostatic brake, which is brought into operation by moving the controller handle backwards beyond the "off" position. The motors are then connected up as generators working on resistance, the latter being gradually cut out until the former are short-circuited. The motors are thus made to absorb the momentum acquired by the motion of the car, and exert a very powerful braking effect.



Connections made by a B 18 Controller of the British Thomson-Houston Company.

The accompanying diagram shows the combinations made by a "B 18" series-parallel controller of the British Thomson-Houston Company, Limited. This type of controller is made for a car equipment of two 35-h.p. 500-volt motors, and is in operation on the London United Tramways and also on numerous other tramways. There are eight "power" notches and six "brake" notches. The diagram shows the connections for "power" as well as for "brake." The numbers in the first column are the "resistance" notches, those in the second the "running" notches, and those in the last the "brake" notches. On reference to the diagram it will be observed that, in braking, the motors are connected up as series generators in parallel, the full starting resistance being inserted in the external circuit on the first brake notch. The value of this resistance is reduced to one half at the third notch, and this is gradually reduced until, at the sixth notch, the motors are short-circuited. With a four-motor equipment the resistance connections are the same as shown in the diagram, and the four motors are connected all in parallel. The No. 5,915 controller for two 30-h.p. 500-volt motors of the Westinghouse has only five "brake" notches, arranged similar to those shown above, but this controller has also only seven "power" notches.

It should be mentioned that the letters G and T in the diagram refer to "ground" and "trolley" connections, and in braking the motors are entirely independent of the trolley connection. The field coils of each motor are represented by F_1 and F_2 respectively.

It is of great importance when using the rheostatic brake to have the hand-brake "off," so that the wheels cannot become locked, thereby rendering the rheostatic brake inoperative. The cause of the recent accident on the Chatham tramways was attributed to inattention to this point, the hand-brake in this case being "hard on" and three notches of the electric brake also. The wheels were locked by the hand-brake, and thus the "electric" brake was rendered useless

When the rheostatic brake is applied suddenly a liberal supply of sand should be given to the wheels, otherwise "skidding" will result. By giving careful attention to this and the previous point, the rheostatic brake can be relied on, especially in cases of emergency. It has one very great advantage over mechanical brakes—viz., that no exertion on the part of the motorman is required for its application—and this is a great feature for cases of emergency. Continual use of this brake certainly gives the motors a "hard time," but considerable weight ought not to be attached to this considering the way tramway motors are now standardised by the leading manufacturers. A. D.

PERSONAL.

Mr. J. M. Keenan, A.M.I.C.E., who for about 12 months has been chief assistant engineer at the Taunton Corporation electricity works, has obtained the appointment of chief assistant engineer at the Torquay Corporation's electric lighting works.

The salary of Mr. H. B. Pooley, gas and electricity manager, Stafford, has been increased from £400 to £450 per annum.

FORTHCOMING EVENTS.

Iron and Steel Institute.—Summer meeting, Barrow-in-Furness, September 1-4.

Institution of Civil Engineers.—Birmingham Students' visit: September to Rhayader.

Municipal and County Engineers.—Meetings: Aberdeen, Aug. 20, 21, and 22; Hastings, September 11 and 12.

British Association.—Seventy-third annual meeting, September 9, Southport.

APPOINTMENTS VACANT.

Chief Assistant Engineers, Hull Corporation, £200 per annum. See advertisement.—Ipswich, salary to commence at £160 per annum. See advertisement in last issue.

Assistant Electrical Engineer, Londonderry, £130 per annum. See advertisement.

Lecturer, Hull Municipal Technical School, £150 per annum. See advertisement in last issue.

Mains Superintendent, Bury, £120, rising to £150 per annum. See advertisement in last issue.

Pupil or Junior Draughtsman. See advertisement in last issue.

Canvassers. See advertisement in last issue.

Three Charge Engineers, Ipswich, salary to commence at £90 per annum. See advertisement in former issue.

Two Switchboard Attendants, Ipswich, salary to commence at £60 per annum. See advertisement in former issue.

Instructor in Mathematics, Governing Body of the Northampton Institute, Aug. 24.

Assistant in the Distribution Department, Croydon. Salary to commence 20s. to 25s. per week, according to qualifications. See advertisement.

Switchboard Attendant. Salary, 10s. per week. See advertisement.

City Electrical Engineer, Bradford. Salary, £600 per annum, by 27th inst.

Imperial Tramways Co.—The directors have declared an interim dividend on the ordinary shares at the rate of 8 per cent. per annum for the half-year ended June 30 last.

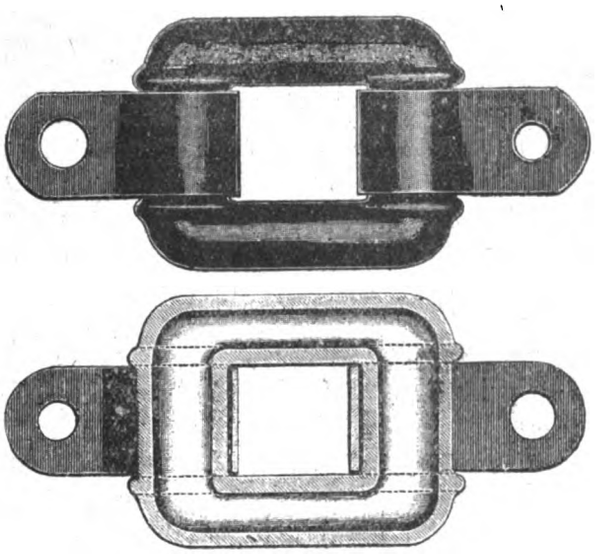
TRADE NOTICES AND NOVELTIES.

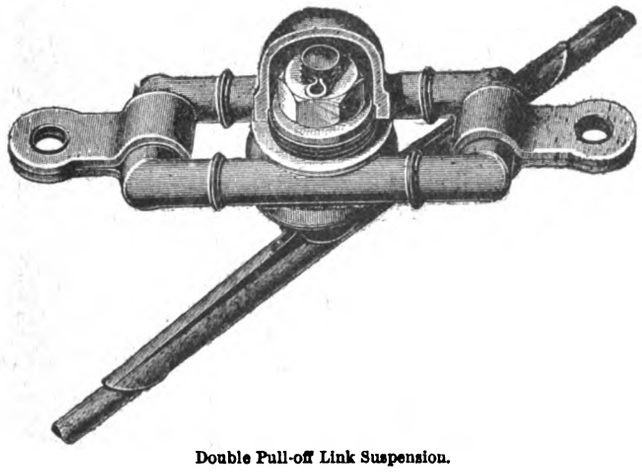
Griffin Insulators.

We illustrate herewith a new type of insulator for overhead trolley wires which has been brought to our notice by Messrs. George Hill and Co., Trafford Electric Works, Cornbrook, Manchester. The single-link strain insulator is designed to replace the globe strain type of insulator, while the double



Single-Link Strain Insulator.

pull-off link suspension replaces at the same time the insulating support for the overhead conductor—*i.e.*, the cap or cone insulator or the insulating carrier bolt, and also the two globe insulators, whereby it is claimed the cost of insulation can be considerably reduced, more especially for single-track roads. It is further claimed that these insulators have an almost unlimited life, since the metal parts are covered with Griffin insulating material, a special kind of ebonite which is extremely



Double Pull-off Link Suspension.

tough and resistant to atmospheric influences. Another advantage claimed for them is that each link provides a double layer of insulation. For further information regarding this type of insulator we must refer the reader to a couple of leaflets on the subject issued by the above firm. A third leaflet emanating from the same source describes the patent comb lightning arrester suitable for use with low and medium pressures.

G.E.C. Leaflet.

From the General Electric Company, Limited, 71, Queen Victoria-street, London, E.C., we have recently received a copy of their "Progress" leaflet for August, in connection with which attention is directed to the reduction the firm are able to make in the prices of their well-known "Peel" switches and other electrical accessories. The "Little Geeko" telephone, which the firm supply for connecting to existing bell wires, is illustrated among other apparatus. This telephone, in every sense a serviceable instrument, may be obtained at prices ranging from the remarkably low one of 7s. 6d. upwards. It represents the capability of British enterprise in regard to the production of such apparatus at a low cost. The special lines of traction supplies listed should commend themselves to tramway engineers. Particular reference may be made to the "Acme" patent splicing sleeve, illustrated herewith. This sleeve was invented by Mr. R. Humphries, chief engineer and manager of the Isle of Thanet Tramways and Lighting Company, Limited, and is claimed to be the most efficient emergency splicer in the market, being equally suitable for temporary or permanent joints. By its means a thoroughly good joint can be made in the trolley wire in the course of a few minutes, and the splice can be permanently soldered up at any convenient time. Directions for using this splicing sleeve are given in the leaflet.

Acme Patent Splicing Sleeve.

New Railway Level.

An improved type of railway level has recently been brought to our notice by Messrs. W. F. Stanley and Co., Limited, Great Turnstile, Holborn, London, W.C. In this level the centre is cast in one piece with, and directly upon, the telescope body and object end. The cast telescope body is cored out to a suitable thickness, so that, although of vastly greater strength and rigidity, it does not weigh as much as the old form of tubular body, collars and stage, while it does away with many separate pieces which are usually soldered and screwed together. The rack is fixed under the drawtube and the pinion is fitted from side to side of the outer cast body, and spindled at each end, so that the pinion has a double bearing in the cast body, which adds greatly to its strength. The level is fitted with clamp and tangent adjustment, tribrach levelling, and patent locking plate so that the level can be used on a wall or masonry as well as on the tripod. The diaphragm is fitted, at the option of the purchaser, with (*a*) webs, (*b*) platinum-iridium points or (*c*) lines on glass. The two latter are set for stadia reading, 1 : 100, so that the distance of the staff is read in the telescope without other measurement. The points do not cover up the divisions of the staff, are permanent in all climates, and may be dusted with a brush. It is claimed that this level is the strongest and most compact yet made.

Electric Bells and Accessories.

From Mr. G. Braulik, 217-218, Upper Thames-street, London, E.C., we have received a copy of the eighth edition of his catalogue (Section B) of electric bells and accessories. This catalogue has attained considerable dimensions, running into some 80 odd pages, and its contents comprise electric bells in great variety, also accessories—such as relays, terminals, indicators, pushes, switches, contacts, staples, wires, jointing materials, wireman's tools, insulators, batteries, magneto machines, battery lamps, holders, etc. We have also received recently from Mr. Braulik a copy of his new list, E M, in which full particulars are given regarding "Eclipse" electricity meters.

The Stirling Boiler.

The Stirling Company, 53, Deansgate-arcade, Manchester, have sent us a copy of their new pamphlet (No. 12), entitled "Economical Steam Raising," which gives some interesting information relative to the Stirling water-tube boiler. We understand that the company will be pleased to send a copy of this pamphlet to any of our readers on application.

Cables, Etc.

We have received from the St. Helens Cable Company, Limited, Warrington, a copy of their new catalogue. In this catalogue full particulars and prices are given of the various types of vulcanised-rubber cables, paper cables, and vulcanised-dialite cables manufactured by the firm. Separate sections are devoted respectively to mechanical rubber goods, asbestos goods, belting, etc.; indiarubber hose, etc.; coachbuilders' requisites, such as "Diallte" mats, carriage tyres, brake blocks, etc.; cycle specialities, including outer covers, pedal rubbers, etc.; and last, but not least, tramway overhead equipments. In the latter section some particulars relating to "Diamant," the firm's new insulating line material, are included. We are told that "Diamant" insulation is tough, resonant when struck, can be dropped on to stone or iron from a height of 25ft. without break or fracture, and is non-hygroscopic, practically non-absorbent, and unaffected by temperature changes. Excellent figures are quoted as the result of severe tests to which the material has been subjected experimentally. It is not necessary to enumerate the various types of pull-offs, hangers,

Digitized by Google

insulators, cars, etc., illustrated. Sufficient has already been said to indicate the diversity of the manufactures turned out by the St. Helens Cable Company. It may be mentioned, however, that the list under notice contains also some excellent interior views of the company's works. We understand that the company is now under entirely new management. Only the most skilled hands are employed in the factory. With regard to cables, these are never sent out of the works unless they have passed the guaranteed test after 24 hours' immersion in water, records of all tests being kept for reference.

Large Order.

In connection with the description of a patent serrated type of oil-can which appeared in our issue of May 29 last, it may interest our readers to know that the makers, Messrs. Joseph Kaye and Sons, Limited, Leeds, have 7,600 of these cans on order for his Majesty's navy.

Steam Accessories.

A new catalogue of steam accessories for central power plants recently issued by the Sir Hiram Maxim Electrical and Engineering Company, Limited, 65 to 67, Gracechurch-street, E.C., contains illustrations of some of the numerous installations of steam-pipes and condensing apparatus, etc., erected by the firm; also full particulars of the "Warwick" detartariser, the "Berryman" improved feed-water heater, the "Berryman" surface condenser, Wright's improved water softener and filter, Paterson's system of condensed water purification, etc.

NEWCASTLE CORPORATION TRAMWAYS.

The following summary of information regarding the tramways as at March 25, 1903, is taken from the report of the general manager and engineer, Mr. A. E. le Rossignol, M.I.E.E.

Single miles of line open for traffic	38½
Passengers carried during year	33,474,122
Population of Newcastle	219,150
Average journeys *per capita* per annum	153
Car mileage run during the year	3,379,119
Average number of passengers per car mile	9·9
Average fare per passenger	1·08d.
Traffic revenue for the year	£150,334. 5s. 8d.
Average traffic revenue per car mile	10·675d.
Total revenue for the year	£153,822. 1s. 8d.
Average total revenue per car mile	10·93d.
Total working expenses for the year (including street-lighting)	£89,313. 2s. 2d.
Average total working expenses per car mile	6·344d.
Average net working expenses per car mile (excluding proportion of costs chargeable to street-lighting)	6·174d.
Percentage of net working expenses to traffic receipts	57·84 per cent.
Total capital expenditure at March 25, 1903	£903,594. 0s. 6d.
Total number of cars in stock at March 25, 1903	148
Number of cars in course of construction	17

HALIFAX ELECTRICITY ACCOUNTS.

The accounts of the Halifax electricity undertaking for the past year show that the expenditure on capital account on March 31 last amounted to £214,056. Below we give abstracts of the revenue account and the general balance-sheet, together with a statement of the electricity generated, sold, etc.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Coal	5,979	8	4
Oil, engine-room stores, etc.	977	11	3
Wages at station	2,172	18	7
Repairs to generating plant, etc.	2,132	13	3
Wages of meter inspectors, etc.	600	19	4

Number of public lamps: 19 arcs, 170 incandescents.

LEGAL INTELLIGENCE.

DAMAGES AGAINST LONDON COUNTY COUNCIL CONTRACTORS.

On Wednesday at the City of London Court, Judge Lumley Smith, K.C., and a jury sat upon the claim of Mr. Arthur Richards, a painter, of Church-road, Mitcham, against Messrs. White and Co., contractors to the London County Council, for damages for injuries sustained during a tram ride.

The defendants have charge of the work of electrification on the South London tram routes, and on the morning of June 25 the plaintiff, while riding on a car between Waterloo and New Cross, leaned over the side, and his head was struck by a street lamp. The track had been diverted from the centre of the roadway to close to the kerb during the laying of the electric conduit system.

The jury found for the plaintiff with £20 damages and costs.

CLAIM FOR WORK DONE.

At the Liverpool Assizes on Monday, before Mr. Justice Bigham, Jenkins Bros., engineers and boilermakers, of Birkenhead, brought an action against James W. Bennett to recover £124. 13s. 8d. for work done.

The case for the plaintiffs was that the defendant, who had been a director of the Leasowe Castle, asked for a price for the removal of an engine used for electric lighting purposes from the palace at New Brighton, and for fixing it in a concrete bed at Leasowe Castle. Plaintiffs agreed to tender to defendant and to look to him for payment. Defendant said it would be all right, but when the account was sent in he declined to pay, on the ground that the contract had been undertaken with the directors of the Leasowe Castle. The defendant, in his evidence, said he purchased the engine for £84 odd, and subsequently there was a sale by him to the Leasowe Castle Company of the engine. He denied that he was liable for plaintiffs' account.

His Lordship decided that there had never been any discharge by plaintiffs of the defendant for his liability, and found for the plaintiffs for the full amount.

A TELEPHONE POINT.

In the City of London Court on Wednesday, Judge Lumley Smith delivered a considered judgment in the action brought by Mr. Henry Lazarus, of the Hermitage, Bushey Heath, against the National Telephone Company for damages for wrongfully cutting off his telephone service.

Plaintiff became a subscriber three years ago to the defendants' service for one year, and he paid a fixed rent charge of £3. 10s. a year. The arrangement had gone on from year to year, but last month, five days before the next payment was due, the defendant company required him not only to pay the £3. 10s., but 30s. in addition for calls and to sign a fresh contract. At first he refused to pay the 30s., but afterwards sent a cheque for £5, and declined to sign the fresh contract. His cheque was returned and the service disconnected.

Judge Lumley Smith said in his opinion the approval of the Telephone Company was requisite at the commencement of each year to enable the hiring to continue. The defendants did not approve of a continuance after the third year, and were not bound to continue. The action failed, but he would give leave to appeal. As the legal aspect was doubtful, he should order each party to pay their own costs.

COMPANIES' MEETINGS AND REPORTS.

ISLE OF WIGHT RAILWAY.

At the half-yearly general meeting on Monday, Mr. Horace F. Tahourdin, the chairman of the Company, presided.

The **Chairman**, in moving the adoption of the report and accounts, which were carried, made a sympathetic reference to the loss that the Company had sustained in the death of Captain H. F. Twynam, who had been a director of the Company for a period of 20 years. It was not proposed at the moment to fill up the vacancy. He also said it might, at a not far distant date, be of advantage to them to adopt electric traction, but the result of their enquiries, so far, was such that they did not at present see their way to recommend anything of the kind. It was a matter that needed very careful consideration. If all the railways in the island were under one management it would, undoubtedly, be very desirable to work the entire system in some such manner. But the present position with the goods traffic, and the delays in connection with the sea traffic, were such that he did not see that there would be any present advantage or economy in working by electricity. There were some electric works in the island from which it might be possible to derive power, but their capacity was very small, and it would require a very great deal of consideration to utilise it to advantage. The shareholders could rest assured that the matter was receiving the constant attention of the Board, and so soon as they saw anything beneficial they would not hesitate to seize the earliest

Digitized by Google

opportunity of adopting the cheapest method of working, whatever it might be, having, of course, due regard to the advantage and safety of the public.

NORTH METROPOLITAN TRAMWAYS.

Mr. George Richardson, who presided at the half-yearly meeting last week, said, referring to the sale to the Metropolitan Electric Tramways, it had not yet been decided what system of electric traction should be adopted, but the London County Council favoured the very costly conduit rather than the overhead system, which only cost one-third as much to instal, and which provincial centres like Birmingham and Glasgow had adopted with success. The long-standing negotiations with the West Ham Corporation had at last been concluded. An agreement was entered into with the Corporation by which the latter agreed to buy the whole of the lines within their district, and also the two depôts at Stratford. The purchase money of the lines was fixed by agreement at £5,000 per mile of single line for the lines authorised by the Act of 1870, and at £5,500 per mile of single line for the remaining lines. The value of the depôts was to be referred to arbitration in the event of their being unable to agree with the Corporation. The sale of the lines was carried into effect as from June 30 last, and since that date the Company had by arrangement continued to work the line on behalf of the Corporation as part of the through system from Aldgate to Stratford. The report was adopted, and the directors were authorised to enter into an agreement of sale with the Metropolitan Electric Tramways.

BAKER STREET AND WATERLOO RAILWAY.

At the half-yearly general meeting of shareholders in the Baker-street and Waterloo Railway Company on Tuesday, **Mr. T. J. Hare,** who presided, said the total expenditure on the line since its commencement amounted to £1,255,000. The western running tunnel between Waterloo and Baker-street was through, and the eastern tunnel would be through in about seven weeks. The running tunnels had been commenced on the extension to the west of Baker-street. An agreement with the Crown had been made for a station site in the Marylebone-road, and the purchase money paid. On the southern, or Elephant and Castle extension, certain work had been done. All possible steps were being taken to push on with the completion of the works, and as there were no financial or physical difficulties in the way, the date of opening could not be very far distant.

The report was adopted, and a further resolution passed authorising the directors to dispose of the forfeited shares in such a way as they thought would be best in the interest of the Company.

BELFAST STREET TRAMWAYS.

At the half-yearly meeting on Tuesday, **Mr. George Richardson** (the chairman), in moving the adoption of the report, said the receipts had increased £2,451 and the expenses £252, the net revenue being £8,238 against £430. The purchase of the Sydenham and Ligoniel tramways, which had been completed, would not impose additional charge upon the revenue account, as the Company had been paying 5 per cent. upon the capital of these enterprises for some years. He ridiculed the draft agreement submitted by the Belfast Corporation to be included in the schedule to the Bill to be promoted next session for compulsory acquisition of the undertaking. He said it would be confiscatory and unjust, and would give the Company worse terms than if the lease had expired and the Corporation were left to their legal rights. The Company asked £445,000, while the Corporation offered £380,000. He did not think that for the sake of saving the difference, Parliament would assist the Corporation to break an agreement solemnly entered into and confirmed by Parliament itself. The report was adopted.

NEW COMPANIES REGISTERED.

Motor Livery, Limited.—Capital, £500. Objects: to carry on the business of manufacturers, etc., of vehicles, whether horse-drawn or propelled by steam, electricity, or other power, and garage proprietors, electricians, engineers, etc. Registered office: 6, Old Jewry, E.C.

COMPANY LIENS REGISTERED.

Electrical Supplies, Rubber, and Ebonite Company, Limited, Sheffield.—Lien registered Aug. 6 for £1,500 debentures; charged on the undertaking and all the property.

Guildford Electricity Supply Company, Limited.—Lien registered Aug. 7 for £1,000 6 per cent. debentures, part of £15,000. No trustees. Charged on the undertaking and all the property, including the uncalled capital.

Bradford.—The tramway employés are still agitating to be allowed to take their meals away from the cars. The men held a midnight meeting on Saturday, when the matter was discussed and delegates were appointed from the various sections to wait upon the Tramways Committee to place a scheme before them. The delegates are not empowered to come to any decision binding the men, but they have to report the result of their interiew to another mass meeting. There was also some discussion on the matter of split turns, a method which does not find favour with the men, but nothing definite was decided.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Harrismith.—The Town Council require tenders for the electric lighting of the town.

Macao.—The Colonial Office at Lisbon invite tenders for the elect lighting of Macao. Tenders by Oct. 21.

Hackney.—The Borough Council invite tenders for arc lamps and pillars and distributing mains. Tenders by 31st inst.

Lisbon.—The Public Works Department require tenders for the public electric lighting of Macao. Tenders by Oct. 21.

Canea.—The Mayor of Canea invites tenders for the lighting by electricity of part or the whole of the town of Canea. Tenders by Aug. 28.

King's Norton and Northfield.—The Council invite tenders for the construction of about three miles of electric tramway permanent way. Tenders by Aug. 29.

Beszterczebanya (Neusohl, Austria).—Tenders are required by the municipality for installation, buildings, etc., of a central station of a minimum capacity of 600 h.p. Tenders by Aug. 31.

Madrid.—The Post and Telegraph Department require tenders for a telephone system in communication with the principal central station in San Lorenzo del Escorial and sub-central stations in Cercedilla. Tenders by Sept. 6.

Glasgow.—The Town Council invite tenders for the supply of 10-ampere arc lamps for street electric lighting. Specifications, etc., may be had at the office of the Lighting Department, 52, College-street. Tenders by 27th inst.

Dublin.—The Port and Docks Board invite tenders for the supply of a 100-ton electric crane. Specification can be obtained at the office of the engineer to the Board, Mr. John P. Griffith, M.I.C.E., Eastwall, Dublin. Tenders by Oct. 5.

Hackney.—The Council invite tenders for arc lamps and pillar and distributing mains. Forms of tender, etc., may be inspected at the office of Mr. Robert Hammond, M.I.C.E., 64, Victoria-street Westminster, S.W. Tenders by 4 p.m. on 31st inst.

Worthing.—The Corporation invite tenders for the reconstruction of their storage battery at the electricity works. Specification of the work can be obtained from Messrs. Burstall and Monkhouse, 14, Old Queen-street, Westminster. Tenders by Sept. 7. See advertisement.

Madrid.—The Posts and Telegraph Department require tenders for installation and working of a telephone system in Gerona for twenty years, and also for installation of telephone between Gijon and Pola de Siero. Tenders by Aug. 25. Specification may seen at this office.

Shanghai.—The French Colony propose to instal motor-propelled tramways. Tenders may be sent by Oct. 31, 1903, to Secrétariat de la Municipalité Française de Shanghai. Particulars may be obtained from l'Office National du Commerce Extérieur, Rue Feydeau, 3, Paris.

Utrecht.—The Town Council will receive tenders for supply and erection of a central electric establishment for lighting, power supply, and working tramways. Contract, conditions, etc., to be obtained at the "Gemeente Secretaire" of Utrecht, on payment of 5fl. (8s. 4d.). Tenders by Oct. 1.

Radcliffe.—The Urban District Council invite tenders for the supply and laying of tramway and lighting feeders, distributing and pilot cables, conduits and accessories. Specification, etc., may be obtained from Mr. S. Mills, clerk to the Council. Tenders by Sept. 5. See advertisement.

Swindon.—The Corporation invite tenders for the supply, delivery, and laying of all the rails, points, crossings, and accessories for the permanent way of the Corporation's tramways. Particulars from the engineers, Messrs. Lacey and Sillar, Manchester and Westminster. Tenders by Aug. 26. See advertisement.

Bermondsey.—The Borough Council invite tenders for the erection of buildings in connection with extensions to the dust destructor house, electric light station, boiler-house, etc., at the Council's works rear of town hall. Specifications, etc., can be obtained at the Town Hall, Spa-road, S.E. Tenders by Sept. 8.

Launceston (Tasmania).—The Mayor and Aldermen invite tenders for the supply of 500 or more electric meters. Particulars may be obtained on application to Mr. William Corin, city electrical engineer, Launceston, Tasmania, or to Messrs. John Terry and Co., 7, Great Winchester-street, London, E.C. Tenders by Sept. 28.

Pietermaritsburg.—The Corporation invite tenders for the supply, delivery, and erection of the necessary poles and overhead equipment for about 5¼ miles of tramway route. Specifications may be seen at Messrs. Mordey and Dawbarn, 82, Victoria-street, S.W. Tenders to Messrs. Ford Bros., 12, Southampton-street, Fitzroy-square, W., by Sept. 7 (noon).

London, S.E.—The London County Council invite tenders for the supply, delivery, and erection in the electricity generating station to be established by the Council at Greenwich of four 5,000-h.p. vertical-horizontal steam-engines, each suitable for driving a three-phase generator. Particulars, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 6.

Portugal.—The "Diaro de Governo" of Aug. 5 contains a notice granting to the Conde de Vizella for 15 years the exclusive concession for automobile service on various roads in the districts of Loanda and Lunda, in Portuguese West Africa, with a preference, under equal conditions, of the establishment of other automobile services in the same districts upon conditions which are stated in the "Diario.""

Ipswich.—The Corporation invite tenders for specification No. 15: arc and incandescent lighting and power circuits and fittings in

Digitized by Google

generating station, offices, car-shed, workshop, and refuse destructor house. Specification, etc., can be obtained from Mr. Will. Bantoft, town clerk, and may be seen at (but not obtained from) the offices of Messrs. Kennedy and Jenkin, 17, Victoria-street, Westminster. Tenders by Aug. 28. See advertisement.

Batley.—The Corporation invite tenders for the mason, joiner, plumber, plasterer, slater, painter, heating engineer, and electric lighting engineer's work respectively, in erection and completion of additions to the present town hall. Plans and specifications, etc., can be seen, and bills of quantities obtained at the offices of Messrs. Walter Hanstock and Son, architects, Branch-road, Batley. Tenders to be sent to Mr. J. H. Craik, town clerk, by noon on Sept. 4.

Birmingham.—The Tramways Committee require the names of contractors who are desirous of tendering for the supply and delivery of materials and fittings as follows: (Section A) manganese steel points and crossings; (B) tapered steel side poles and bracket arms; (C) suspension ears, pull-offs, section insulators, and other overhead materials; (D) hard-drawn copper trolley wire and stranded steel span wire. Mr. John Price, city engineer, Council House, Birmingham.

RESULTS OF TENDERS.

West Ham.—The order for the tramway cable has been placed with the British Insulated and Helsby Cables, Limited.

Reigate.—The Town Council have accepted the tender of Nightingale and Sons, Reigate, at £2,023, for additions to the electric lighting station, Wray Common-road.

Hove.—The Hove Electric Lighting Company have placed an order with W. T. Henley's Telegraph Works Company, Limited, for the supplying and laying, on the solid system, of paper-insulated feeder cables.

Radcliffe (Lancs.).—The Urban District Council have accepted the tender of W. Brierley, Church-street, Radcliffe, at £55, for fitting the existing market hall with electric lighting wires and other appendages complete.

Colchester.—W. T. Henley Telegraph Works Company have secured the contract for the supplying and laying of tramway feeders for the Colchester tramways as sub-contractors to Messrs. J. G. White and Co.

Bradford.—A tender has been accepted for the works and materials necessary for the electric lighting at the Cartwright Memorial Hall, Lister Park, Bradford, by the Corporation, of G. H. Woods, Slacke, and Co., Corporation-street, Blackburn.

Dewsbury.—A tender has been accepted for the supply and delivery of steam coal at the Corporation Electricity Works, Bradford-road, by the Electricity Committee, of Crawshaw and Warburton, Limited, Dewsbury, 1,000 tons screened nuts and 2,000 tons pea slack.

Ipswich.—The Corporation have accepted the following tenders for the supply and delivery of electricity meters: Reason Manufacturing Company, Lewes-road, Brighton, for 2½, 5, 10, and 15-ampere meters; Ferranti Limited, Hollinwood, Lancashire, for 20, 30, and (if required) 50, and 100-ampere meters.

Cheadle and Gatley.—The Town Council have accepted the tender of Messrs. Steel, Peech, and Toyer as follows: fishplates, £6. 8s. 4d.; rails, £6. 8s. 4d.; tiebars, £8. 17s. 6d.; and bolts, £18. 10s.; and the tender of Messrs. Askham Bros. and Wilson for points and crossings, No. 2 contract, at £34. 15s.

Derby.—The Town Council have accepted the following tenders: Chloride Electrical Storage Company, Trafford Park, Manchester, accumulators, £2,812. 15s.; Lancashire Dynamo Company, Clifton Junction, near Manchester, balancers and reversible boosters, £791; Johnson and Phillips, Victoria Works, Old Charlton, Kent, switchboard, £1,276.

Egypt.—The Allgemeine Electricitäts-Gesellschaft, of Berlin, recently established an underground telephone line between Cairo and Alexandria for the Société Egyptiennes des Telephones, while Messrs. Siemens and Halske, of Berlin, installed the necessary electrical apparatus at the great Assouan dam, and have secured the contract for the electric lighting of the barracks at Khartoum.

Weymouth.—The Town Council have accepted the following tenders: E. Danks and Co., boilers, £1,850; International Electrical Engineering Company, engines and dynamos, £3,192; J. Hitchen and Sons, crane, £280. 10s.; International Engineering Company, switchboard, £1,860. 9s.; Tudor Accumulator Company, storage battery, £156; Oliver and Co., arc lamps and posts, £704. 3s.; Aiton and Co., pipework, £3,195; Johnson and Phillips, mains and feeders, £11,321. 17s. 10d.

BUSINESS NOTES.

TRACTION.

Brighton.—Application is to be made for a loan of £20,000 for electric tramways along Preston-road to Preston Village.

Salford.—Lieut.-Colonel von Donop on Wednesday last week made an inspection of three new sections of the Salford tramways, which are shortly to be opened for traffic.

Lowestoft.—The last weekly traffic returns of the electric trams showed that 82,883 passengers had been carried, and that the receipts had been £378. 19s. 10d.—this with only about 11 of the 15 cars in use.

Rotherham.—For the week ending Aug. 12 the receipts on the Corporation tramways amounted to £598. 1s. 8d., or an average of £85. 8s. 9d. per day. Of the total, the Tinsley section contributed £315. 18s. 2d.

Yeadon.—The Leeds and Guiseley tramways scheme having been dropped, a general meeting of the Rawdon, Guiseley, and Yeadon Council is to be arranged to decide upon the mode of procuring tramways for the district.

Alpine Railway.—A German syndicate is at present making surveys for an electric funicular railway from Grindelwald to the Gleckstein cabin on the Wetterhorn. Negotiations for procuring the necessary land are now in progress.

Manchester.—A deputation has been appointed in connection with the Tramway Committee to wait upon the officials of the Manchester Carriage Company with a view of arranging terms for the taking over of the horse cars and tramway track within the borough.

Darlington.—So much advance has been made with laying the new electric line that consequently the old service has now been stopped. Mr. O'Dowd is the lessee of the old tramways, and will have a like position in connection with the new electric system.

Halifax.—Great satisfaction is said to prevail in the Brighouse district at the decision of the Corporation to extend their tramway system from Hove Edge into the centre of Brighouse. The extension, which will measure 1 mile 6 furlongs, is to be completed in two months' time.

Porth and Pontypridd.—The Rhondda Urban District Council have declined to receive a deputation from the Pontypridd Council with a view to the working of the whole of the Porth-Pontypridd tramway by the Pontypridd Council, because they are at present negotiating in reference to the tramway.

Wednesbury.—An arrangement has been arrived at between the Corporation and the tramways company on terms by which the electrification of that portion of the South Staffordshire line between Wednesbury Bridge and the White Horse Hotel will be commenced this week and completed before Christmas.

Swansea.—The plans and specifications for the construction of the new lines to Sketty, Bryn-road, and Brynhyfryd have been completed by Mr. Prussman, the borough electrical engineer, and Mr. Geo. Bell, the borough surveyor, and will be submitted to a meeting of the Corporation Tramways Committee on Sept. 2.

Ossett.—The Town Council have decided to apply to the Board of Trade for an order under the Tramways Act for power to make and construct tramways within the borough, and a sub-committee has been empowered to act with the joint committee of the Dewsbury and Soothill Nether Councils in any further arrangements.

Wakefield.—The construction of the electric overhead tramways which will eventually connect Wakefield with Leeds in the one direction, and Wakefield with Horbury and Ossett in the other, was on Thursday last week commenced almost immediately opposite the Vine Tree Inn, Newton, by the contractors, Messrs. Dick, Kerr, and Co.

Scarborough.—The Corporation propose to purchase the system of electric tramways about to be established in the borough by the tramways company. The company are understood to be favourably disposed towards the transaction, which will involve an outlay of about £6,000. It is sought to settle the question prior to the commencement of the work of construction, which is fixed to begin on Oct. 1, 1903.

Battersea.—The widening of Falcon-road, by taking away the front gardens of several houses along that thoroughfare, has already commenced, and no doubt a great improvement will soon be effected. A few houses along Battersea-rise are also being pulled down, as a part of the London County Council scheme for laying a tramway along North-side, Clapham Common, and Battersea-rise to Wandsworth.

Liverpool.—The tramway traffic returns for the fortnight ending Aug. 1 shows receipts of £21,516, as compared with £20,993 for the corresponding period last year, the passengers carried numbering 4,620,000, against 4,510,000 for the same fortnight in 1902. The last horse car of the old service was discontinued on Saturday. The Bank Holiday receipts were £5,560 for the three days this year and £5,500 for the same period 1902.

Ashton-under-Lyne.—At the last meeting of the Town Council, the Chairman of the Tramways Committee (Councillor Andrew) said he was sorry that his expectation that the new electric cars would be running by Ashton Wakes could not be realised. The cause of the delay was that the order for track work had been sent to America by the Manchester Corporation because they thought that the American firm could supply them in the shortest space of time.

Upper Norwood.—Proposals have been made to the local authorities in favour of the introduction of trams into Upper Norwood. A canvass of the districts through which the proposed line would pass has been taken, and the returns show a majority of 3 to 1 in favour of the system being introduced. Demands will be made to the Croydon and Lambeth Councils urging the extension of the existing lines from Thornton Heath and Herne-hill to Upper Norwood, and from Herne-hill to the Crystal Palace.

Light Railways.—The Board of Trade have confirmed the following light railway orders made by the Light Railway Commissioners: (1) Gloucester Corporation Light Railways Order, 1903, authorising the construction of light railways in the city of Gloucester; and (2) County of Gloucester (Gloucester and Brockworth) Light Railways Order, 1903, authorising the construction of light railways in the parishes of Wotton St. Mary (Without), Barnwood, Hucclecote, and Brockworth, in the county of Gloucester.

Newcastle.—At the last meeting of the Tramways Committee plans and estimates were presented for the further extension of the tramway system. The engineer's estimate for the track is £108,000, and the electrical engineer's estimate for equipment, etc., £132,000. The report will be circulated among the members for presentation to the Council. It was agreed to ask the Council to give the committee sanction to proceed immediately with the line from Heaton-road down

Digitized by Google

to Benton-road, with a single track laid across Armstrong Bridge, joining the line at the Jesmond-road section.

Nelson.—The construction of the tramways is now completed, and the cars are running regularly over the whole length from the Colne boundary on the one hand to the Higherford Bridge at Barrowford on the other. The work has been completed expeditiously and greatly to the credit of the electrical engineer, Mr. W. A. Fraser. The total capital cost of the line will be something like £15,000, and the lines will pay if the fares reach £65 per week. With the shorter length only at work that at present has been far exceeded.

Dundee.—In the estimates of income and expenditure of the tramways for the current year the total income is put down at £44,050, and the expenditure at £44,670, leaving an adverse balance of £620. The expenditure is expected to be slightly over £2,000 more than last year, for which wages, electricity, maintenance of permanent way, interest, sinking fund, and depreciation are mainly responsible. Rents, rates, and taxes are down by more than £100, but most of the other items show slight increases. The payment of £2,100 to the tramway company appears as in former years. The revenue is wholly received from tramway receipts and advertising.

Burton-on-Trent.—On Monday the tramways were opened to the public, and a very successful start was made. The receipts amounted to close upon £100. The scheme for laying about 5¾ miles of lines, connecting the centre of the town with Branstone, Horninglow, Winshill, and Stapenhill, was prepared by the borough engineer (Mr. Lynam) and Messrs. Kincaid, Waller, and Manville, of London, the cost being estimated at £85,000. The contractor for laying the lines was Mr. Finnigan, of Northampton, and 20 cars were supplied by Messrs. Dick, Kerr, and Co., of Preston. The power is generated at the Corporation electricity works, and sold to the Tramways Committee at a rate of 2d. per unit for the first hundred thousand units, and 1½d. per unit afterwards. Should the car receipts come up to 9d. per car mile, an annual profit of £2,250 is anticipated.

Leeds.—Mr. Smithson, who resigned the chairmanship of the Tramways Committee because the City Council declined to accept his recommendation respecting the tramway manager's salary, has forwarded to the committee the following letter: "Gentlemen,—The Lord Mayor has conveyed to me, in terms which I greatly appreciate, your expression of confidence, and your desire that I should withdraw my resignation of the chairmanship of your committee. I have most carefully considered your request, together with various representations made to me as to the inconvenience that might be caused by a change in the chairmanship of your committee at a period so near to the end of the year, and have decided that, if it is still your general wish that my resignation should be withdrawn, I will at once resume my duties as chairman for the unexpired period of this year." The committee subsequently passed the following resolution: "That this committee learns with pleasure of the decision of Mr. Councillor Smithson to withdraw his resignation of the chairmanship."

Withington.—The Manchester Corporation Tramways Committee have offered to enter into an agreement with the District Council to take a 30 years' lease of the proposed tramway lines, paying the Council a sufficient rental to cover the interest and sinking fund payments in respect of the capital expenditure incurred by the Council in constructing the permanent way of such tramways, the Corporation to undertake at their own expense the repair and maintenance of the lines during the period of the lease. The Council have replied that they consider after their experience of the working of the tramways that all future lines should be double lines, and that in order to provide double lines it would be necessary to carry out works of road widening, for which the Council had not obtained powers. Further, the Withington Committee were not prepared to recommend for consideration any proposals for a lease of the tramways unless the Corporation agreed to pay the cost of constructing the tramways, as well as the total cost of carrying out the necessary road improvement and the cost of obtaining the necessary powers, the Corporation to undertake at their own expense the repair and maintenance of the lines during the period of the lease.

London County Council Tramways.—On the South London lines from the bridges to Brixton and Streatham the County Council are endeavouring to combine electricity with the existing cable system from the upper end of Brixton-road, and in carrying this out several difficulties appear to have arisen, especially the question whether the cable would stand the strain of the new cars, which, although smaller than those used on the Balham and Tooting line, are yet much heavier than the ordinary two-horse cars. A trial is being made with seven cars between the Streatham terminus and Westminster Bridge, and the result appears to be satisfactory so far. It is stated that the "transformation" at Brixton-road transforming station is being effected in two minutes. The electrification is practically completed between the Elephant and the northern end of Camberwell-green, and a big gang of men are at work laying down the network of conduit and rails at the southern end. In Peckham-road the conduit has been laid for a considerable distance, and the horse cars are stopped short at Pomeroy-street, Queen's-road, in order that the work at the New Cross end may be expedited. The line from Camberwell-green to Vauxhall, which was opened a fortnight since, promises to be the best paying of the whole system.

The Tramways Act.—The report of the Board of Trade of their proceedings under the Tramways Act, 1870, during the session of 1903, states that 14 applications were made to the Board of Trade in December, 1902, for provisional orders under the Tramways Act, 1870—namely: Barrow-in-Furness, Burton-upon-Trent Corporation, Bury Corporation, Cardiff Corporation Extensions, Halifax Corporation, Horsforth Urban District Council, Huddersfield Corporation, Ilford Urban District Council, Keighley Corporation, Leeds Corporation, Leeds and Guiseley, Newcastle-upon-Tyne Corporation, Portobello and Musselburgh, and Ramsbottom Urban District Council. All the applications included power to construct new or extension tramways, and all except three were promoted by local authorities. The aggregate length of the proposed tramways was 14 miles 5 chains of double line and 21 miles 56 chains of single line, and the estimated expenditure was £447,922. The Halifax and the Ilford applications were withdrawn by the promoters. Twelve applications were granted by the Board of Trade and provisional orders made. The Leeds and Guiseley order was not, however, proceeded with owing to the failure of the promoters to make the prescribed money deposit. The remaining orders were submitted to Parliament for confirmation in two Confirmation Bills, which received the Royal assent on Aug. 11.

Paris Metropolitan.—Acting on the recommendation of the commission of enquiry into the recent disaster on the "Metro," the Prefect of Police has advised the company of the new measures of reform and the precautions for safety of passengers which will be required to be introduced on its system. The modifications are divided into three series. First, those to be put into immediate execution; second, those to be introduced before Sept. 5; and third, those to be begun by Nov. 1. The first series includes the appointment of inspectors, one for every five stations; every short-circuit is to be reported to an inspector, who shall thereupon determine the measures to be adopted. Independent petrol lights are to be placed in every station to indicate the way out, and all needless barriers and the penny-in-the-slot machines, etc., which now encumber the passages and platforms are to be removed. In the second series the company is required to isolate completely the motorcar from the other cars composing the train. All offices and installation boxes at the stations are to be constructed of incombustible material, an independent system of lighting is to be installed, special fire-alarms are to be placed in telephonic communication with the nearest fire station. The third series contains a recommendation to study other systems of traction possessing fewer dangers of fire or panic than the one at present in use. The third rail carrying the electric current is to be properly guarded, so as to protect passengers who may be obliged to walk along the track from danger of electrocution. All the stations are to have at least two exits, and air-shafts are to be constructed between the stations.

Ramsgate Enquiry.—Lieut.-Colonel von Donop held an enquiry on Wednesday into the circumstances attending the tram accident at Ramsgate last Wednesday, by which 21 persons were injured. John Collins, the driver of the runaway car, said all went well until the top of the hill into Bellevue-road was reached, when he noticed that something was wrong. He immediately applied all three brakes. The car got beyond his control, and ran into another car standing on the interlacing lines. Albert Coppen, the conductor, stated that the car was not proceeding at more than walking pace when it reached the top of the hill. Then it appeared to suddenly shoot forward. Witness at that time was busy taking fares, and before he could do anything the collision occurred. He was certain the sand-box was in good order when they started from Margate. It was untrue that passengers were thrown over the top of the runaway car. Knell, the driver of the other car, said, when he saw that a collision was unable, he shut off power. At the moment of the impact he estimated the speed of the runaway car at 20 miles an hour. The rails were very greasy through rain. He admitted that bogie cars like those involved in the accident were difficult to control when descending gradients. The manager of the company, Mr. Humphries, thought the slipper brake was useless as an emergency brake. The inspector disagreed with this view, saying brakes of that type were being used all over the kingdom. Mr. Humphries said he found nothing to account for the accident. From the driver's evidence he thought that the electric brake was so applied as to be inoperative, causing the wheels to skid. That was the only cause to which he could attribute the accident. Replying to the town clerk, witness said slipper brakes were impracticable with their bogie cars. The company had gone fully into the matter. The inspector said it appeared that the sanding arrangements arrangements were perfectly in order, but he thought the weakness was in the brakes, and to that point he should refer in his report. There was no doubt the trolley arm came off first, rendering the electric brake useless. He recommended that in future all cars should stop at the top of the hill. This concluded the enquiry.

Taunton.—The Street and Highway Committee are considering the following report of Colonel von Donop in regard to his inspection of the tramways on July 19: "I was accompanied at the inspection by representatives of the Corporation and of the tramway company. The lines are about 1¼ miles in length, and they were opened for traffic not two years ago. Over a portion of the route where the line is on a gradient, and the roadway on that account keeps fairly dry, the condition of the track is satisfactory, but the greater part of the route is along a flat road at a low level, and on this portion the track is undoubtedly in an unsatisfactory condition, though I am not prepared to say that it is at present actually dangerous. The company, however, fully admit that the method of construction has not been a success, and they are prepared to reconstruct it, the only point in dispute being what the form of construction shall be. The present form is as follows: each rail is laid on a separate concrete base, 1ft. 9in. in width, and there is one granite block on each side of each rail; the space between the rails is filled in with tar asphalt. The company now propose to make the concrete base continuous between the two rails, and to pave for the whole distance between the two rails and for 18in. on the outside of each rail with granite setts. The Corporation are, however, desirous that wood blocks should be substituted for granite setts, and this is one point of difference between them and the company. The Corporation are of opinion that wood blocks would be a more lasting form of construction and would be less noisy. The company, on the other hand, point out that the roadway outside the track is macadam, and that the maintenance of a wood track in the centre of a macadam roadway would

Digitized by Google

be both expensive and unsatisfactory. I informed the Corporation that it was my opinion that the track as proposed by them would not be found a satisfactory arrangement, that it would not wear well under the conditions which obtain at Taunton, and that its condition would be a constant trouble both to them and the company. On the other hand, the form of construction now proposed by the company is what has been in use over a very large number of lines in England for several years, and has been found to give general satisfaction. I therefore recommend them in their own interests to agree to the company's proposals."

Tramways Assessment.—The Assessment Committee of the Brentford Union have, on the advice of their rating surveyor, Mr. Cook, fixed the total value of the London United Tramways in their district for rateable purposes at £18,551, with a gross of £40,456. These figures are split up between the parishes in the following way, care being taken as near as possible that the apportionment should be on the basis of mileage of line: Acton—rateable value £2,020, and gross value £4,419; Ealing, £1,725 and £4,189; Hanwell, £1,540 and £2,784; Chiswick, £9.706 and £15,123; Old Brentford, £611 and £1,755; New Brentford, £91 and £375; Isleworth, £774 and £3,832; Heston, £1,018 and £3,682; Twickenham, £1,067 and £4,297. Chiswick naturally takes premier position because in it are situated the main stations of the company, the power-house, the offices, and the great car-sheds. Acton has also some car-sheds, and so have Hanwell and Heston, which accounts for the preponderance of value in these parishes over Ealing and Isleworth, the value of the buildings having been added to the length of line and cables. These figures apply to the rates of March, 1902, September, 1903, and March, 1903, except so far as Isleworth, Heston, and Twickenham are concerned. Prior to 1903 Isleworth and Heston pay on £308 and £960 respectively, the reason being that the Twickenham-road lines and the extension to Hounslow Heath, though open and securing large profits, had not been brought into the assessment. As regards the Twickenham lines, they have not been brought into any assessment prior to April last, although they had been open to Cole's Bridge in August, 1902, and from Richmond Bridge to King-street a few weeks later. The arrangement of these figures was not arrived at without considerable trouble. The tramway company have now given notice of appeal to quarter sessions against the decision. The Assessment Committee have decided to recommend the Guardians to allow them to defend the appeals.—In the year 1900 the borough treasurer brought before the Bolton Tramways Committee the question of the income-tax assessment on the tramways undertaking, and the claims of the surveyor of taxes to tax the profits to a much larger extent than the borough treasurer considered fair and legal. Up to that time the revenue account had not been debited with more than the annual instalment of loans repaid, or sinking fund as it is sometimes called. Then a statement was submitted allowing for depreciation on capital at the rate of 8 per cent. on the construction of tramlines, 3 per cent. on buildings, old lease, goodwill, etc., 5 per cent. on electrical equipment, 10 per cent. on cars and rolling-stock, tools, machinery, office fittings, etc., the depreciation being £16,298, which included £6,336. 17s. 2d. loans repaid. After a lengthy appeal before the local commissioners of taxes this sum was admitted, with the exception of the allowance for buildings, goodwill, etc. The committee authorised the treasurer not to charge the loan repayment to tramways revenue account as he had hitherto done, for it was understood that the item loans repaid was really depreciation, and that the loans ought to be repaid out of the depreciation allowed. This was a very important decision, and was a new departure in municipal accounts. It saves the committee income tax on the amount of loans repaid yearly, which has gone up from £6,000 in 1901 to nearly £13,000 for last year, for the Inland Revenue department had always charged income tax on this sinking fund item previously. The accounts for the year ended March 31, 1902, were prepared on similar lines, but the treasurer went further in his income-tax appeal this year, and claimed a rebate tax on the cost of relaying the permanent way, which in 1901-2 had cost an outlay of £51,919, and this was allowed, with the exception of £10,031, which was for doubling the track, and that this was consequently new capital. This important income-tax appeal has been largely adopted by the municipalities of the kingdom, and we understand that Glasgow especially has saved the tax on over £100,000 by following in the wake of Bolton. Glasgow is charging full depreciation against tramways revenue account, in addition to the sinking fund.

LIGHTING AND GENERAL.

Dover.—The Corporation Electricity Purchase Bill has received royal assent.

Wednesbury.—Sanction has been received to the electric lighting loan of £11,000.

Stewat Electrical Syndicate.—Mr. G. S. Pitt, liquidator, has been appointed receiver and manager.

Walmer.—The Council have confirmed a resolution applying for a provisional order to supply electrical energy in Walmer.

St. Pancras.—It is stated that the Council have made £46,612 profit on their electric lighting plant within the last 10 years.

Fulham.—The Guardians' estimate of the cost of the provision of a new nurses' home includes £300 for electric lighting installation.

Thetford.—Messrs. Burrell and Sons have obtained permission to extend their electric cable underground to premises on London-road on the usual conditions.

Carlisle.—The Electricity Committee have appointed a sub-committee to consider the charges at present made for the supply of current to private consumers.

Bo'ness.—The Town Council have appointed Mr. Ogilvie, of King Bros., Leith, consulting engineer in connection with the proposed electric light and power scheme.

Rawtenstall.—The Corporation will supply the Rossendale Valley Tramways Company with the necessary electrical energy for the working of their undertaking within this borough.

Accrington.—Mr. H. Ross Hooper has held an enquiry into an application of the Corporation for sanction to borrow £550 for the provision of additional machinery at the electricity works.

Kingswinford.—The laying of the electric lighting cables is progressing rapidly, and Messrs. Parsons and Sons have delivered 24 lamp columns. The work of setting the columns has commenced in Wall Heath.

National Telephone Co.—With the object of focussing all the business in connection with new orders, this Company has formed a contract department, with offices situated at Salisbury House, London-wall, E.C.

Pontypool.—The Callender Cable Company, Limited, are now laying down the cables for supplying electrical power to the collieries and other industries of the town for the South Wales Electric Power Distribution Company.

Loughborough.—The Town Council have empowered the town surveyor to act with Mr. C. H. Gadsby, engineer to the electricity scheme, in preparing the architectural work in connection with the electricity power station.

Stalybridge.—Mr. Gibbings is preparing a general statement as to the lighting of the generating station. The generators are now ready for testing at Preston, and four motor-generators are to be ready for testing about the 8th prox.

Blackheath and Greenwich District Electric Light Co.—The directors have resolved that an interim dividend at the rate of 7 per cent. per annum be paid upon the cumulative preference shares for the half-year ended June 30.

Govan.—The Corporation have obtained sanction to make large additions to the electricity station in Helen-street. The buildings are to cost £10,000, and within the next two years the Corporation will lay down plant to the value of £40,000.

Taunton.—The charge for current to the free-wired consumers will be reduced 1d., or 5d. instead of 6d. per unit, for current consumed between Oct. 1 and March 31 next, but the charge is to stand at 6d. for the following six months or summer half.

Sowerby Bridge.—The offer of the Northern Counties Electricity Company, Limited, to light the street lamps for 1,266¾ hours, and to provide and fix the necessary poles and lamps, at a charge of £1. 8s. 6d. per lamp of 40 c.p. per annum, has been accepted.

Brighton.—The accounts of the Lighting Committee of the Town Council for the year ended March 31 show that the year's working of the electric light undertaking has resulted in a net profit of £7,984, upwards of £3,000 of which will be applied to the relief of rates.

King's Lynn.—The Council have resolved to extend the plant at the electricity works at an estimated expenditure of £5,500, and to apply for sanction to a loan of £11,320 to cover the cost of the extension, and also previous excess and technically unauthorised expenditure.

New Branch.—Owing to rapidly increasing business, the British Westinghouse Electric and Manufacturing Company, Limited, have opened a new branch, under the management of Mr. W. S. Doran, at York City and County Bank-buildings, Sheffield, for the Sheffield district.

London Electric Supply Corporation.—The directors have declared an interim dividend for the half-year ended June 30 last at the rate of 6 per cent. per annum on the preference shares, payable on Sept. 1. The transfer books will be closed from the 17th to 31st inst. inclusive.

Berwick.—The sanitary authority have entered into an agreement with the Urban Electric Supply Company for the lighting of the streets. Arc lamps are to be erected of 1,000 nominal candle-power, and to be fixed on standards supplied by the company, while the incandescent lamps are to be of 25 c.p.

Isle of Man.—The Isle of Man Steam Packet Company are having Marconi installations made on their vessels. The first installation is on the "Empress Queen," which almost daily carries 2,000 passengers each way between Douglas and Liverpool. It is expected the first test will be made on to-day's passage to Douglas.

New Canadian Cable.—It is stated that a syndicate will shortly be formed to arrange for the establishment of a direct independent cable service between England and Canada, with a tariff of 6d. per word for ordinary cablegrams and 3d. per word for Press messages. We understand that Mr. Roland Belfort, Anglo-Canadian Cable Syndicate, 34, Great St. Helen's, E.C., is one of the movers in the scheme.

Greenock.—Mr. James Robertson, burgh electrical engineer, in his last report, states that 37,534 units of electricity were generated in Greenock for private and public supply during the five weeks ending Aug. 1, an increase compared with this period last year of 9,237 units, and 78,477 units were generated for traction supply, an increase of 5,636 units. The number of consumers has increased from 275 to 346. Only 40 private houses in Greenock have introduced electric light, which is somewhat unsatisfactory. The engineer is of the opinion that the reason electric light has made such little headway amongst private householders is because the "flat" rate has been too high. He proposes, therefore, that it be reduced from 5½d. to 4½d. per unit, a figure which is still 15 per cent. in excess of the average price obtained last year from all consumers. The pumping station at West Quay in connection with the condensing plant is now in operation, and the results are reported as in every way satisfactory. The accounts for the past year show a credit balance of £649. 11s. 9d.

Digitized by Google

Imperial Tramways Co.—For the half-year ended June 30 last the directors of this Company have declared an interim dividend on the £10 ordinary shares of 8 per cent. per annum. The dividend warrants will be payable on and after the 20th inst.

W. T. Henley's Telegraph Works.—An interim dividend at the rate of 12 per cent. per annum for the half-year ended June 30, 1903, will be paid on the ordinary shares of this Company on Sept. 1 next. The half-year's dividend on the preference shares at the rate of 4½ per cent. per annum will also be paid on the share date as usual.

Canada.—Some time ago the Radial Electric Company unsuccessfully tried to secure the right of way through the streets of Toronto, and endeavoured to have a measure passed by the Ontario Provincial Legislature giving them this privilege. They have now appealed to the Dominion Government for the franchise. The case is exciting considerable local interest.

Manufacture of Electric Accumulators.—The Home Secretary has issued draft regulations, under Section 79 of the Factory and Workshops Act, 1901, dealing with the manufacture of electric accumulators. They are intended to come into force on Oct. 1, and will be in substitution for the special rules for electric accumulator works made under the Factory Act of 1891.

Parkfield Works, Stockton-on-Tees.—We are informed that Messrs. Ashmore, Benson, Pease, and Co.'s works will close on Saturday, Aug. 15, until Monday morning, Aug. 24, for stocktaking, that no goods can be received or dispatched between these dates, and that material forwarded to arrive between these dates will be refused, and senders made liable for any demurrage that may be incurred.

Willesden Polytechnic Electrical Engineering Society.—At the last meeting of the society, Mr. Frederic H. Taylor, A.M.I.E.E., in the chair, a paper was read by Mr. T. Lawrence on the subject of the "Nernst Lamp." The author showed some interesting diagrams illustrating the various types and also the working parts of this lamp, and the excellent description given evoked considerable discussion.

Morley.—Mr. J. E. Ellis, borough electrical engineer, in his last report, states that the output from the electricity works during the four weeks ending July 14 was 6,223 units, as against 4,193 units for the corresponding period of last year. The lamps connected to date was 10,312. The borough engineer has been instructed to report to the next meeting as to the construction of Park-street sub-station and as to the repair of the same.

Thames Boat Building.—The Thames Valley Launch Company, Limited, who are building a number of boats for foreign orders, have just sent off from their Weybridge works the first of a series of special service inspection steamers for the use of the Egyptian Government on the Nile. There will be altogether 10 or 12 of these small screw steamers, and each will be in charge of an inspecting officer, for whom every comfort is provided on board in the way of sleeping and living accommodation.

Tottenham.—At the last meeting of the Urban District Council the Electricity Committee submitted an amended scheme for the carrying into effect the provisional order obtained by the Council in 1902 for the lighting of the district by electricity. The committee recommended the adoption of the scheme, and that application be made to the Local Government Board for sanction to a loan of £70,000 to defray the cost of the work. After a long discussion the further consideration of the scheme was postponed.

Llandovery.—At a meeting of the Town Council and three representatives of Llangadock district on Monday, the question of placing Llandovery and Llangadock in telephonic communication with other towns was considered. A communication from the Postmaster-General was read to the effect that this could be done provided a guarantee for £72. 10s. per annum would be forthcoming. It was resolved that Llandovery Town Council become guarantors to the extent of £50 a year, and that Llangadock provide the balance of £22. 10s. per annum.

Bristol.—We note from the annual report of the city engineer, Mr. T. H. Yabbicom, M.I.C.E., that during the year ended March 25, 1903, the Electrical Committee laid 28·56 miles of cables, and formed 10·58 miles of trenches for them. The total expenditure was £2,910, including £419 for laying private services, alterations to sub-stations, etc. Amongst other works, we note the building of a new coroner's court and mortuary at a cost of £2,248, and 10 workmen's dwellings, which give accommodation to 42 persons, and which entailed an expenditure of £2,256.

Newton Abbot.—The Newton Urban District Council have refused to grant permission to the Urban Electric Supply Company to lay cables to Kingsteignton. Mr. H. C. Pay, engineer and manager, has agreed to give the Council an undertaking that the granting of their approval to allow the company to extend to Kingsteignton could not in any way affect the Council's option to purchase so much of the undertaking as was in the urban district of Newton Abbot when the opportunity to purchase arrived. The matter is before the Lighting Committee of the Council.

Change of Name.—The New British Arc Lamp Company, Limited, Horsell-road Works, Holloway-road, London, N., have changed the name of their company to New British Engineering Company, Limited. The company have opened a department for the manufacture of switchboards and for every kind of electrical and mechanical work, and have secured the services of Mr. William Thomas Burbey as works manager, under whose supervision the whole of the work will be carried out, and of Mr. Ernest Paine, who will act as the company's commercial representative.

The Temple.—There has been a difference of opinion for some time past between the authorities of the Inner Temple and the Post Office respecting the introduction of the latter's telephone service into the Inner Temple, the benchers wishing to have the overhead whilst the Post Office contended for the underground system of pipes and wires. The benchers have now given their consent, and the work of laying the underground wires was commenced in the Inner Temple yesterday. The Post Office telephone has been in operation in the Middle Temple on the underground plan for some months past.

Bilston.—Since the introduction of the electric trams the progress of electricity in Bilston has been very rapid. Mains were laid by the Electric Corporation for Power Distribution, and many of the leading tradespeople at once had their premises attached. The District Council also supported the Corporation, and as quickly as possible arranged terms for the lighting of their main buildings. This work was practically completed on Saturday, and the town has now its market, baths, free library, reading-room, town hall, Council chamber, and offices all illuminated with electricity. The result is a great improvement.

Catalogues Received. — Allgemeine Elektricitäts - Gesellschaft Berlin, Mitteilungen aus dem Kabelwerk, No. 30. Insulation Materials: I. Hartgummi.—Berliner Telephone Mfg. Company, 117, Queen Victoria-street, London, E.C., Leaflet No. 62, automatic telephones for reply and call system.—Geoffroy and Delore (manager, A. H. Hunt), 115-117, Cannon-street, London, E.C., single and twin lead-covered cables, standard lighting and power cables, cables for town mains, steel-armoured cables, concentric cables, flexible cords, aerial cables, motorcar flexibles. — Walsall Electrical Company, Limited, 115 117, Cannon-street, E.C., arc lamps and accessories, also pocket price-list of "Walsall" open-type dynamos and motors.

Accumulator Manufactories.—We have just received from the Home Office at Whitehall draft regulations which have been prepared under the Factory and Workshop Act of 1901 for regulating the manufacture of electric accumulators. These regulations, issued in draft form, will come into operation on Oct. 1, unless any parties interested succeed in convincing the authorities that there are valid objections to the same. These objections have to be sent to the Secretary of State within 40 days from the 10th inst. A casual glance through the draft now before us tends to the belief that the regulations are reasonable, and that if properly enforced they will do much to prevent lead-poisoning occurring amongst the workmen in our electrical accumulator manufactories.

Wireless Telegraph Conference.—The members of the recent international wireless telegraph conference were entertained by the Gesellschaft für drahtlose Telegraphie. The arrangements included visits to the works of the companies which were the founders of the new company—viz., Siemens und Halske Aktiengesellschaft and the Allgemeine Elektrizitäts-Gesellschaft. The apparatus of the new company, made according to the "Telefunken" system, were then shown and explained by Count Arco (technical manager), Herren Dr. Seibt (chief engineer), Herren Schmidt and Schloemilch, the latter showing for the first time his new polarisation cells, which are said to be simple of construction and effective in preventing electrical disturbances to wireless telegraphy apparatus.

Boston.—The Paving and Lighting Committee reported at the last Council meeting of the Town Council that they had received communications from two firms to the effect that, as the Corporation had not taken advantage of the electric lighting order adopted some time ago, they intended to apply to the Board of Trade for powers to light the town by electricity. The consideration of the matter was adjourned for a month. The question of lighting the new municipal buildings by electricity was again considered, and having regard to the fact that an electric lighting installation may shortly be erected in the town, the Council, by 13 votes to 7, abstained from affixing the borough seal to the contract for £715, accepted at the last meeting.

Gravesend.—The resident engineer's report for the three months ending June 30 is as follows: units supplied to private consumers, 15,777; units supplied to public lighting, 14,070; units supplied to tramways company, 96,280—total, 126,127; approximate works costs—fuel, £642; oil, water, stores, etc., £25; wages, £148; repairs, £12. 11s.—total, £327. 11s.; approximate revenue per unit sold, 2·26d.; approximate works cost per unit sold 1·56d.; number of consumers supplied 98; increase since March 31 last, 17; equivalent number of 8-c.p. lamps supplied (private lighting), 5,875. It is proposed that a small generating set of 100 kw. be obtained at a cost of about £1,250. Sanction has been obtained to the borrowing of the sum of £1,070 for electric lighting purposes.

Birkenhead.—The demand for electricity from the Corporation's undertaking for the quarter ending June shows a great increase as compared with the corresponding quarter of last year. The figures were 94,787 units by 512 consumers, as compared with 71,568 and 371 consumers. To ordinary lighting consumers were supplied 25,768 units at 6d., 15,263 at 3d., and 14,572 at 1½d. for full quarters, and for incompleted quarters 893 units at 6d., 354 at 3d., and 223 at 1½d. Power and heating consumers took 3,159 units at 2½d., 1,976 at 2d., and 174 at 1½d. Craven-street generating station took 240 units each at 4d. and 3d., and 2,002 at 1½d.; Woodside Ferry obtained 12,417 units at 2·2d.; the Watch Committee, 14,904 units for street-lighting; and Bidston and Nocturum consumers, 2,572 units at 7d. The average price obtained in the quarter from all classes was 3·99 per unit, as compared with 4·23 per unit for the corresponding quarter last year. From the list of average prices for energy, it appears that public-houses paid the least, 2·67d. per unit, and churches and chapels the most, 5·97d. per unit.

Surbiton.—The formal opening of the new electric lighting station at Tolworth will not take place for a few weeks yet, but the premises are practically completed, and there is sufficient plant to supply light and power to the whole of the district where the cables are laid. The current was turned on for the first time last week by Mrs. Patrick Shaw, wife of Mr. P. G. C. Shaw, chairman of the Parliamentary Committee of the Surbiton District Council, who was also present, together with the Rev. J. F. Medley, Mr. F. Packham, Mr. R.

Digitized by Google

Thirlby, Mr. F. J. Bell (deputy clerk to the District Council), Mr. S. Mather (surveyor), Mr. Petersen (Callender's, Limited). Mr. Wickham (Edmundson's Electric Corporation), Mr. Talbot (of Messrs. Hopkinson and Talbot, consulting engineers to the District Council), Mrs. Talbot, Mr. H. M. Gill (manager of the works), and Mr. C. P. Medley (assistant manager). The plant at present consists of a Bellis-Morcom 120-h.p. high-speed steam-engine direct coupled to a 90-kw. Fowler dynamo. Steam is supplied by two Babcock and Wilcox water-tube boilers, and the switchboard is by Fowler and Co., Limited.

Glasgow.—The quantity of electricity sold during the last year to private consumers was 10,419,488 units, being an increase of 24¼ per cent on the preceeding year. The number of consumers at May 31 was 7,013, being an increase of 1,639 during the year. The number of motors in use was 1,059, with a total horse-power of 4,597, compared with 682, with a total horse-power of 3,086, on the corresponding date. The number of units consumed for power purposes was 1,560,509. The maximum load or demand made upon the generating stations was on Dec. 22, when it was 9,371 kw., compared with 7,950 kw. in the previous year. The telephone accounts for the year ending May 31 show a total revenue of £55,723 and working expenses £15,967, making the net revenue £39,761, out of which the following requirements had to be met: interest, £6,642; sinking fund, £5,806; Post Office royalty, £3,405; and terminal fees, £1,497—a total of £17,352, leaving a balance of £22,408. Adding the surplus of £398 from the preceding year the balance is £22,807, which is dealt with as follows: proportion of rental applicable to year 1903-4 carried to suspense account, £20,714, leaving a surplus of £2,092, which the sub-committee recommend should be carried to a reserve fund. The expenditure on capital account for the year was £78,556.

Redditch.—The Urban District Council have received a supplementary report from Messrs. Burstall and Monkhouse, of London, the experts engaged to report upon the town's electric supply undertaking. As to the present value of the plant compared with the original cost, the experts considered that, taken as a going concern, the value of the engines was 80 per cent. of the original cost, and the rest of the plant 88 per cent. of its original cost. Provided the plant was maintained out of revenue and insured against accident, it was not necessary to create a depreciation fund. They could not actually tell the condition of the cables without taking them up, which it would be inadvisable to do. The engineers expressed the opinion that it was wise to push the sale of current for power purposes, even at present prices, as the plant at the generating station had to be run during the day whether the current is sold for power purposes or not. Redditch compared favourably with 14 other towns having an approximately similar output. The cost of adapting the present gas-producing plant for the use of bituminous instead of anthracite coal would be £500. Properly speaking, there should be spare plant equivalent in output to that of the largest unit, and on that basis the output at the Redditch station, supposing the new plant to work satisfactorily, should be about 200 kw.

London Gazette.—An order has been made out in the estate of Edward Baldwin Pym, lately carrying on business at Bar-chambers, Scarborough, York, now residing at 29, Bramham-gardens, South Kensington, London, electrical engineer, as follows: discharge suspended for two years; bankrupt to be discharged as from July 10, 1905. A dividend is to be declared in the estate of William Scholes (trading under the style or firm as Scholes and Son), electrical engineer and contractor, residing at 49, Main-street, Failsworth, Lancaster, and carrying on business at 39, Corporation-street, Manchester, Lancaster, and occupying portion of a shop at 10, Rochdale-road, Middleton, Lancaster, as a branch store. The last day for receiving proofs is Aug. 29, 1903. Christopher Jenkins Dibb, official receiver, Byrom-street, Manchester. An order for discharge has been made out in the estate of Alfred Carlton Blyth, Avenue House, Hill-street, St. Albans, Herts, lately carrying on business with William Turvey, under the style or firm of Turvey and Blyth, at the Standard Electrical Works, St. Stephen's-hill, St. Albans, Herts, engineers and contractors. A dividend of 13s. 11½d. in the £ has been paid. Date of order, July 20, 1903. The partnership heretofore subsisting between Edward Roberts and Arnold Roberts, carrying on business as electrical engineers and contractors, at 15 and 17, Lee-street, Thornton-road, in the city of Bradford, under the style or firm of Roberts Bros., has been dissolved by mutual consent as and from Aug. 1, 1903. All debts due to and owing by the said late firm will be received and paid by Arnold Roberts.

Private Bills.—The private Bills passed during the last session include 218 private Bills, seven Electric Lighting Order Bills (confirming Board of Trade orders in respect of 52 districts), and two Tramway Confirmation Order Bills (confirming Board of Trade orders in respect of tramways). For railway purposes new capital is required to the amount of £10,500,000, including increase of capital in the case of most of the large companies, notably the City and South London, £600,000; Great Northern and City Railway, £450,000; Great Northern, Piccadilly, and Brompton (Various Powers), £250,000; Ulster and Connaught Light Railway, £117,000; and the Metropolitan District Railway (Various Powers), £900,000. New tramway capital required is as follows: Manchester Southern Tramways, £250,000; Mid-Yorkshire Tramways, £372,000; Coventry Electric, £18,000; Chatham and District Light Railways, £240,000; Notts and Derby Tramways, £750,000; Preston and Horwich, £500,000; Gosport, Fareham, and Cosham, £18,000; Harrow-road and Paddington, £60,000; Hastings, £60,000; Stroud and Cheltenham, £200,000; South Lancashire, £200,000. Altogether there were 54 Tramway Bills introduced, but 23 of these were promoted by the London County Council, various borough councils, and urban district councils. Electric power companies account for £4,500,000 as follows: Scottish Central, £600,000; Carmarthenshire, £600,000; North-Western Electricity and Power Gas, £1,500,000; Fife, £600,000; Shropshire and Worcestershire, £450,000; Somerset and District, £750,000. First, however, amongst the Bills that have either been dropped by the promoters or suspended or rejected by Parliament we note: *Metropolitan District Railway (Works), £2,100,000; Luton, Dunstable, and District Tramways, £140,000; Macclesfield and District Tramways, £240,000; Rochester, Chatham, and Gravesend Tramways, £180,000; Wakefield and District Tramways, £100,000; Antrim, Down, Armagh, and Belfast Electric Power, £400,000; City and North-Eastern Suburban Railway, £4,450,000; *Central London Railway, £3,150,000; *Clapham Junction and Marble Arch Railway (1), £1,500 000; *Clapham Junction and Marble Arch Railway (2), £2,040,000; *North-West London Railway, £700,000; London and Brighton Electric Express, £450,000; *Great Northern, Piccadilly, and Brompton Railway (Extensions), £2,400,000. * These Bills were suspended owing to the appointment of the Royal Commission on London Locomotion, but altogether schemes involving capital expenditure of over £30,000,000 fell through.

German Electrical Companies.—The annual reports of two of the principal German electrical companies—the Schuckert Company and the Continental Company for Electrical Enterprises, both of Nuremberg—have just been issued. The Schuckert Company, which, it may be remembered, was amalgamated last April with the Siemens and Halske Electrical Company, of Berlin, has now succeeded in making the income meet the expenditure on a capital exceeding £2,000,000. The accounts show an available surplus of £6,300, which is to be carried forward, as against the enormous deficit of £769,000 in 1901-2. The Continental Company for Electrical Enterprises—the so-called financial trust of the Schuckert Company—does not make so good a showing, and for the third year in succession does not pay a dividend. The balance-sheet shows a loss of £21,000 for the year, and a total deficit of £58,900. The *Financial Times* says: On the question of the amalgamation with the heavy electrical departments of the Siemens and Halske Company under the title of the Siemens-Schuckert Works Company, with a capital of £4,500,000, the report of the Schuckert Company states that during the three months which have elapsed since the fusion, the new company has worked satisfactorily, and that the orders received have exceeded those booked by the original firms during the corresponding period of last year. This indicates a notable improvement in the economic situation, which it is hoped will make further progress, although a recovery from the prevailing low prices is still desired. As far as the British Schuckert Electrical Company is concerned, the directors of the German parent company, which holds shares in its offspring to the extent of £18,000, state that they hope, as a consequence of the close relations with the Siemens and Halske Company (whose light electrical engineering branch was not included in the fusion, and is being continued by the original company), that they will be able to associate the English interests with those of the Siemens and Halske Company. This seems to point, a correspondent adds, to a possible amalgamation of the British Schuckert Company and of Siemens Bros. and Co., Limited, of London. Among the numerous electric lighting, tramway, and railway enterprises in which the Continental Company for Electrical Enterprises is interested as owner, constructor, or shareholder, is the suspended high-level electric railway which the company built between Barmen and Elberfeld, and extended to Vohwinkel two months ago. The two years' working of the greater portion of this railway have proved the advantages of the system, which is also being proposed for Berlin and Hamburg, and has been suggested, if a detailed scheme has not already been prepared, as a means of transport by the construction of an overhead line across London.

COLONIAL NOTES.

Durban.—The Durban Corporation have completed their "outer" circle of tramways, and passengers are now able to make a complete circuit of the town without disembarking. Since the installation of electric trams some 15 months ago the old horse cars have almost fallen into desuetude, and at the present time only about half a dozen are running. In a few months the horse trams will be entirely replaced by electric cars, which, by the way, cost £1,000 each.

Potchefstroom.—The latest phase in the progress of Potchefstroom is the decision of the Government to at once proceed with a scheme of electric lighting for the whole of the town. This step has been hastened by the formation of a local company, with the announced intention of pushing forward a lighting scheme, but as the Government has decided that no permission shall be given to any private company to either erect wires or cross streets, its operations must necessarily be confined to a single block. Up to the present the town, which has progressed at an unprecedented rate, has been without any street-lighting, so that there has been vigorous agitation for the electric scheme.

PROVISIONAL PATENTS, 1903.

AUGUST 10.

17307. Improvements in and relating to electric tramways and means for propelling vehicles. James Townsley Pearson, 8, St. James's Hall, Burnley.

17367. Improvements in safety devices for strong current overhead conductors. Christian Cornelius van der Valck, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17374. Improvements in magneto-electric machines and appurtenances for cooling and pumping. James Harding Lancaster, 114, Liberty-street, New York.

Digitized by Google

AUG. 11.

17399. Process of decomposing water by electrolysis. George Thomas Fuery, 11, Burlington-chambers, New-street, Birmingham. (William FitzMason McCarty and Winfield Scott Beebe, United States.) (Complete specification.)

17451. Improvements in or relating to electric joints or connections for railway trains. Simon Savelsohn, 111, Hatton-garden, London.

AUG. 12.

17466. Improvements in or connected with incandescent electric lamps. George Davis, 15, Victoria-street, London.

17464. Improvements in electric signalling mechanism. Percy Richard Julius Williss, Fife House, Kingston-on-Thames. (Albert E. Caughey, United States.)

17482. Improvements in electric arc lamps. William Squire, 51, Deansgate-arcade, Manchester.

17488. Improvements in electric railway trains or railway vehicles. Arthur Petzenbürger, 15, Took's-court, Cursitor-street, Chancery-lane, London. (Complete specification.)

AUG. 13.

17564. Improvements in junction or inspection boxes and like inspection fittings used with electric wiring. Ernest White and James Waldron, Prince's-chambers, Wolverhampton. (Complete specification.)

17568. Improvements in electrical heating devices. David Huntley, 115, Cannon-street, London.

17587. Improvements in the manufacture of electrodes for electrolytic purposes. George William Johnson, 47, Lincoln's-inn-fields, London. (The Chemische Fabrik Griesheim Elektron, Germany.)

AUG. 14.

17597. Improvements in electric or steam or other pile-driving apparatus. Herbert Thomson Garvie, 69, Victoria-street, Westminster, London.

17601. Improvements in system of electric lighting. Henry Leitner and Richard Norman Lucas, Rose Villa, Byfleet.

17602. Improvements in reversing mechanism for dynamos. F. Webb Manley, Rose Villa, Byfleet.

17605. An improved trolley head and arm for electric traction wires. Jasper James Carter, 1, Anglesea-villas, Ballsbridge, County Dublin.

17632. Improvements in electricity meters. Hadyn Thies Harrison, 46, Lincoln's-inn-fields, London.

17643. Improvements in the arrangement of steel magnetic armatures for electromagnet pairs. Luigi Cerebotani and Albert Silbermann, 111, Hatton-garden, London. (Complete specification.)

17644. Means for electrically operating from a distance typewriting machines, type-printing, telegraphic apparatus, and the like. Jacob Pilsatneeks, 36, Chancery-lane, London.

17663. Improvements relating to electric accumulators. Barthélémy Becker, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

AUG. 15.

17702. Improved electric battery. René Hubert Edmond Phillippart, 52, Chancery-lane, London.

17721. Improvements in or connected with coin-freed electricity meters. Frederick John Beaumont, 173, Fleet-street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published September 3, 1903.

1902.

17460. Regulating lever and instantaneous brake applicable to machines driven by electric motors. Bradbury and Co., Limited, and Drybrough.

17663. Method of and means for securing shades, reflectors, or the like used in connection with incandescent electric lamps. Morrison and Butterworth.

17676. Electric lamp globes. Böhm and Böhm.

17690. Electric arc lamps. Lake. (General Electric Company).

17841. Methods of and means for producing, shaping, and employing electric current pulses. Loring.

18816. Commutators for dynamo-electric machines. British Thomson-Houston Company, Limited. (Erben.)

18923. Direct-current electricity meters. Lake. (General Electric Company.)

19563. Electrical switch devices applicable to rheostats, commutaters, and the like. Lake. (General Electric Company.)

19572. Trolley wheels for electric traction. Lake. (General Electric Company.)

19665. Electricity meters. British Thomson-Houston Company, Limited, and Holden.

20240. Electric conduit railways or tramways. Hadfield and Galbraith.

20647. Construction of electrical transformers, choking coils, and the like. Siemens Bros. and Co., Limited. (Siemens und Halske Aktiengesellschaft.)

21229. Automatic electric switches. Offord and Marsh.

21631. Electric arc lamps. Davy.

22023. Insulators used for electrically dividing into sections trolley wires as used on electric railways. Brecknell, Munro, and Rogers.

22783. Electrical switches. Cox.

24031. Overhead guards for electric cars. Hindle.

24033. Oiling vertical electric motors which are worked intermittently as in the case of driving centrifugal machines direct by an electric motor. Macfarlane.

1903.

1514. Clockwork-operated electromagnetic circuit controlling apparatus. Danziger.

5693. Lamps with electric lighting device and supplemental wick. Lind and Carlsson.

7481. Controllers for electric motors. Stuart. (Date applied for under International Convention, April 2, 1902.)

8690. Electrical burglar alarm for the protection of safes, vaults, and the like. Weatherby.

9932. Treating materials by radiated or reflected heat in electric furnaces. Howorth. (Trollihättans Elektriska Kraftaktiebolag.)

12467. Impedances for telephone and other electric circuits. Warren and Campbell.

14566. Means for electrically driving centrifugal machines. Haddan. (American Tool and Machinery Company.)

14930. Electricity meters. Aron.

15065. Keyboard telegraphic transmitters. Kotyra.

15266. Electrical switches. Dorman and Smith.

NOTES.

Cheap Electric Light.—A German contemporary states that, commencing on Jan. 1, 1904, the price of electric light in Berlin will be reduced 27 per cent.—*i.e.*, from 55 pfennigs to 40 pfennigs (about 6½d. to 5¾d. English money) per kilowatt-hour—and that the price for electric light in that city will then be cheaper than in any other large city. This reduction is being made with a view to competing more closely with gaslight.

Marconi Experiments.—Signor Marconi is ever at work. The eminent inventor left Liverpool on Saturday for New York on the "Lucania," and intends during the voyage making some important experiments. An independent apparatus has been fitted up on the aft mast of the vessel, and Signor Marconi will direct his experiments to ascertaining the actual power required to transmit messages a certain distance on a moving ship. He promises to publish his results on arrival at New York should they prove sufficiently interesting.

Electric Alarms. — At Hampstead the public swimming-baths have been equipped with a system of electric alarms as a precaution against accident to the bathers. In the event of a bather getting into difficulty the attendant rings an electric bell in the office and in each of the other baths. A disc is at once displayed indicating at which of the four baths help is needed, and the attendants are able to go to the spot without delay. In a surprise test made by the Baths Committee it was found that five men were brought to give aid to an apparently drowning person in just 35 seconds.

Hertzian Waves in Navigation.—An American inventor, Mr. H. W. Ladd, claims to have discovered a means for using Hertzian waves in obtaining bearings at sea when the objects, owing to a fog or storm, are invisible. This consists of a coherer circuit electrically connected with an upright conductor, so shielded that waves are only received from a transmitter on another vessel or at a shore station when a lateral opening of the shield is in proper range radially with the vessel or station. The shield is movable, and at its lower end has a pointer moving over a compass card. When the coherer in circuit gives a signal the range is determined.

Books Received.—"New Instruments of Precision from the Ryerson Physical Laboratory," by Robert A. Millikan. This is a full description of some new pieces of apparatus devised by members of the department of physics: (1) a substitute for the Attwood machine; (2) a "moment of inertia" machine; (3) a Young's modulus apparatus; (4) a vapour-tension device. It is published by the University of Chicago Press. We have also to acknowledge "Practical Physics of the Steam Boiler," by Mr. Frederick J. Rowan, A.M.I.C.E., M.I.E.E. The book, published by Messrs. P. S. King and Son, Westminster at 21s., contains over 300 illustrations, and runs into 600 odd pages.

Radium and Blindness.—A case is reported from New York in which the sight of a child who had been totally blind for eight years has been partially restored, as the result of a combination of the use of radium and the X-rays. Dr. Amon Jenkins and Mr. Wm. J. Hammer were responsible for the experiment, which consisted principally in holding against the forehead, the base of the brain, and the temples of the child, several tubes of radium, ranging from 75 to 7,000 radioactivity. A momentary sensation of light was the result. According to the correspondent who sends the information, the child an hour afterwards was able to distinguish objects in the street. He does not go so far as to say that the cure is permanent, but adds that the sensation produced is that of a shadow being cast over one whose sight is normal.

Electricity in India.—The Government of India, under the present Viceroy, seems anxious to take full advantage of electricity so far as the conditions existing in that country will permit. A useful Act has been passed for the controlling of the use of electricity for light and power purposes in India, and the Government itself has been among the first to adopt electricity for light and punkah-pulling, and is now extending its application to the driving of machinery in the State workshops. In connection with this work we hear that the Government has accepted in principle a scheme for establishing a central workshop and store at Rurki for the repair and testing of electrical appliances, and for the issue of stores required in connection with electrical installations in cantonments. Several such installations have been made, and the satisfactory results obtained have doubtless been the dominant factor in urging the Government to energetically pursue its work in this direction.

Wave Motor.—Information reaches us of a trial of Millar's wave motor, which took place recently at a small seaside place near Dunedin, in New Zealand. The contrivance consists of a wooden float about a ton in weight, to the four corners of which ropes are attached. The ropes are taken up over loose pulleys and joined by four chains to ratchet wheels on a shaft. As the waves rise the weights pull the chains down, and are so held by cogs. As the float goes down with the fall of the sea it exerts a pulling force on the spindle, which drives a countershaft with a pulley attached. The power thus obtained was used to drive a small dynamo with a 25-c.p. lamp, and also a circular saw. With the ton float used about 3 h.p. is stated to have been obtained. Unfortunately, all attempts to harness the power of the sea are met by the difficulty that there is no protection against rough weather, and we are afraid the above device is no exception to the general rule. It is thus obviously impossible to invent an arrangement which will serve efficiently except under favourable conditions, such as would naturally be selected for the trial of a new invention.

Artificial Graphite.—The manufacture of artificial graphite at Niagara Falls has assumed a very prominent position in the graphite industry in the last two or three years. The production in 1902 amounted to 2,358,828lb., as compared with 2,500,000lb. in 1901 and 860,750lb. in 1900. The sole producers are the International Acheson Graphite Company, who began operations in 1897 with a product of 162,382lb. The output of last year consisted of 885,591lb. of graphitised electrodes, and 1,475,237lb. of artificial graphite in the granular or powdered form. The electrodes were used in electrolytic processes for the production of caustic soda and of chlorine and metals in chlorine solution, also in electro-metallurgical processes, such as the production of calcium carbide, the electric smelting of copper and iron ores, and the manufacture of various iron alloys. The artifical graphite in the form of grains and powders was used chiefly in the manufacture of paint, dry batteries, and commutator brushes, although a considerable quantity was used in the manufacture of lubricants, in electroplating work, and in certain chemical processes requiring a carbon of exceptional purity.

The Earth as a Condenser.—In the "Digest" of the *Electrical World* for Aug. 15 an abstract of a paper by Koepsal is given discussing the rôle of the earth in wireless telegraphy, in which two interesting points are brought

Digitized by Google

into prominence. One of these is the small electrical capacity of the earth, and, therefore, the improbability of its playing any part, as has been suggested, in the transmission of large quantities of electrical energy by utilising it as an element in a resonant circuit. The author calculates a special case, assuming conditions that might be approximated in practice, though a vertical conductor extending 2,700 yards in the air is scarcely a practical assumption. With resonance established, the maximum current rush would then not exceed 15 amperes, and the total flow of current would be only ·0009 coulomb. An important conclusion of the investigation is, however, that in wireless telegraphy the capacity of the earth may be utilised to great advantage. If the premises of the author are correct, the conditions of resonance can be satisfactorily met without great difficulty by proper design of apparatus, in which case sending signals half around the earth could be as readily accomplished as sending them over short distances.

Rubber-Producing Creeper.—Mr. W. A. Hearsey is stated to have discovered the rubber-producing creeper, Rhynchodia Wallichii, growing abundantly in the Nyanglabin division of the Pegue district, in India. The rubber obtained from this creeper is said to be clean and of good quality, and could no doubt be cultivated with advantage both to the planters and the rubber-using trades. From an Australian journal we hear of a renewed effort which is being made to cultivate the rubber plant in Queensland, Australia. Some successful attempts were made a short time ago to obtain and prepare rubber in Queensland, and samples were sent to England, obtaining a fair price. The sap was obtained by making incisions in the bark of the white mangrove trees, which grow plentifully in the swampy lands along the coast of Central Queensland, and was allowed to run into tins that were fastened on the trees. It was afterwards placed in earthenware jars, put in boiling water, and then worked up by hand until the rubber was produced. In this simple, crude manner very good elastic rubber was obtained, which fetched 4s. per pound in this country. The demand for rubber is ever increasing, and it is surprising that this trade has not been more fully developed by planters. For many years to come enterprising Colonials might find in the cultivation of the rubber tree a source of indigenous wealth.

Electric Light and Power Plants of the United States.—Some of our American contemporaries have published a valuable report issued by the United States Census Offices giving statistics of the electric light and power plants of the United States for the year ended June 30, 1902. This report includes central stations only. It does not embrace isolated plants, plants operated by electric railway companies, or plants that were idle or in course of construction. Thus we find that there are 3,619 such establishments in operation, of which 2,804 are private and 815 in municipal hands. The total capital expenditure represented by these stations is the huge sum of £100,436,302, while the total earnings from operation during the year under review were £18,717,082. On the other hand, the total expenses amounted to £13,537,615, and it is noticeable that under this heading the salaries and wages bill is very nearly as heavy as the supplies and materials item, the respective totals being £4,110,398 and £4,562,951. Under the heading of power plant equipment, we are somewhat surprised to find that the total horse-power of the waterwheels is less than a fourth of that of the steam-engines. The figures in each case respectively are: number 5,921, horse-power 1,377,041; number 1,378, horse-power 381,134. A mass of figures is given further on in the report, from which we gather that the total output for the year was 2,437,218,732 kilowatt-hours. A final report is promised, which will give an analysis of the above totals and present statistics for other phases of the industry.

A Second Mosely Commission.—Hardly has Mr. Mosely concluded the work in connection with his recent Labour Commission to America than he is engaged in making arrangements for dispatching an Education Commission across the Atlantic. Both the United States and Canada will be toured by the commission, and the various universities and schools inspected. About 30 delegates, forming the commission, will leave these shores early in October; each delegate represents a different branch of education. Among the delegates will be representatives of the county councils of England, Scotland, Ireland, and Wales, from whose presence Mr. Mosely expects to achieve great results. The commissioners also include Prof. W. E. Ayrton, F.R.S., professor of physics in the Central Technical College; Mr. R. Blair, M.A., B.Sc., representing the Department of Agriculture and Technical Education in Ireland; Mr. Magnus Maclean, M.A., D.Sc., professor of electrical engineering in the Glasgow and West of Scotland Technical College; and Mr. W. Ripper, professor of engineering, University College, Sheffield. The delegates will be required to make separate reports, which will be published in a collective form in the spring. It may be safely anticipated that the volume when issued will reveal information of the highest importance with regard to the progress of technical education on the other side.

Improved Galvanic Battery.—A recent German patent relates to improvements in galvanic batteries of that class which are constituted by or composed of a series or plurality of separate dry cells. The improvements refer to the production of a battery which is capable of being kept in store and transported in an absolutely dry condition, and of being rendered fit for use at a moment's notice by the addition of a suitable liquid or electrolyte into the separate cells constituting the battery. The object aimed at is claimed to have been secured by the introduction of certain novel features of construction and combinations of parts. The dry cells consist each of a zinc or other metallic cylindrical electrode, or of a carbon electrode having a cylindrical or prismatic cross-sectional area, and placed within the metallic cylinder. The space between the two electrodes is filled up with blotting-paper or other suitable material capable of sucking up the electrode. A plurality of these cells is arranged within a suitable socket or frame-shaped casing, the individual cells being separated from one another, and the surrounding casing by some suitable insulating material. When required for use one has only to remove the covers from the cells and to fill them up—that is to say, to soak the blotting-paper with any convenient electrolyte, such as ammonia solution. The covers are then replaced and the battery ready for use. Insulating rings at the open ends of the cells or zinc cylinders respectively prevent any short-circuiting of the cells by any overflowing electrolyte.

Schmidt Superheater.—We are able to give the results of an interesting trial carried out this month of a Schmidt flue-fired superheater which Messrs. Heaton and Co., Limited, have supplied to the Greenbank Corn Mills, Preston. The superheater, which is of 500 square feet heating surface, is fitted to a 7ft. 6in. by 21ft. 3in. Lancashire boiler, and the steam is used for driving a single-cylinder non-condensing engine of 13in. diameter by 36in. stroke, 67 revolutions per minute. The trial lasted five hours, and the following satisfactory results were

Digitized by Google

obtained. The boiler pressure by gauge was 66lb. per square inch. The temperature at the superheater was 570deg. F., and at the engine 436deg. F. Using superheated steam, the coal burned per hour was 2·5cwt., whereas a previous trial with saturated steam required 3·5cwt. of coal; so that the saving of coal equals 1cwt. per hour, or 28·5 per cent. The indicated horse-power being 67·3, the steam consumption per indicated horse-power was with superheated steam 22lb., with saturated steam 36lb. This represents a saving of water with superheated steam equal to 14lb. per i.h.p. hour, or 39 per cent. It is estimated that the total weekly saving of coal and water using the superheater is represented by 31s., an annual saving of £77. 10s. The cost of the complete superheater installation was £270, and allowing 10 per cent. for depreciation, the net saving due to the superheater comes out at £50. 10s., or 18½ per cent. interest on the capital outlay. The above figures are taken from the official results of the trial, and may be regarded as accurate.

Central-Station Development. — Prof. Elihu Thomson contributed a paper to the recent convention of the National Electric Light Association of America, in which he reviewed central-station development during the past 25 years. At that date dynamos were of exceedingly small capacity, when one using 25 h.p. or 50 h.p. had a very large output. The evolution of steam practice in central stations from high-speed belted engines to slow-speed direct-connected units was reviewed, bringing the author down to modern steam-turbine practice. Looking to the future, the author put aside as improbable the conversion of fuel into electrical energy, inasmuch as no promising signs of its possibility were forthcoming; but it seemed that it would be necessary at last to turn to those forms of prime movers which had inherent possibilities of developing much higher efficiencies in the use of fuel than the steam-engine. At present in relatively very small units the internal-combustion engine, such as the oi or gas engine, had shown efficiency nearly double that of the best steam-engine plants. It seemed probable that an efficiency of heat conversion about three times better than was attained with steam would some day be practicable in large units. The engines would naturally be of the large reciprocating type and comparatively slow speed, unless some form of gas-turbine was developed, a matter upon which serious doubts might be expressed. Such a machine would demand the pumping of the air and gas prior to their combustion. Various other matters in connection with gas-engine practice were briefly discussed. In the considerations advanced in the paper the use of water power was purposely neglected.

Electrodes.—Three English electrochemists (Messrs. J. Hargeaves, J. W. Stubbs, and J. Kearsley) have patented recently a method for a peculiar construction of anodes or electrodes, consisting partly of carbon for use in electrolytic cells, and probably designed more particularly to be used in Mr. Hargreaves's own apparatus. From a description in *Electrochemical Industry*, we gather that the object in view has been to get an electrode which offers little resistance to the electric current, and the parts of which may be readily renewed when worn or broken. The arrangement consists of a bar of metal connected to the source of electricity. The bar may be made of two strips riveted together in such a way as to form openings at intervals, or these openings may be worked out in a solid bar. Passing through these openings, but not fitting closely into them, are nipples or bars of carbon. In order to make electric contact between the bar and nipples, melted lead or another suitable metal is cast into the openings between the bar and the nipples. This also holds the nipples firmly in position. In order to still further reduce the resistance and improve the contact, indentations or perforations may be arranged into or through the nipples, which are also filled with melted lead. The bars are then preferably coated with tar pitch or similar impervious insulating material, after which they are covered with Portland cement or any other insulating compound. The coating of impervious material prevents the access of the electrolyte to the metal bar and its corrosion. The ends of the nipples project through the cement covering and are fitted closely into openings in the blocks or pieces of gas or retort carbon, from which the current passes into the electrolyte. The extremities of the nipples are covered with cement or similar material, to prevent wearing at those points. The nipples may also be covered with sheaths of insulating material, in order to further protect them.

Radiation from the Nernst Lamp Glower.—In the August number of the *Physical Review* Hartman contributes a long article giving the results of a spectrophotometric investigation of the luminous radiation from the Nernst lamp glower under varying current densities. The apparatus used was a Kirchoff spectrometer, having a callimeter with two unilateral micrometer slits, which was adapted for the purpose of the investigation. The arrangement and standardisation are described in detail. As a standard source of light an acetylene flame burning under constant pressure was used. The Nernst lamp employed was a 104-volt alternating-current lamp. The diaphragmed acetylene flame used as a standard was determined in terms of the Hefner standard. Currents from 0·2 ampere to 1·5 ampere were used. The author arrives at a number of conclusions, from which it appears that at the rated normal current strength the radiation from the glower of the Nernst lamp is relatively rich in the more luminous waves of the spectrum. It exhibits no marked selective radiation. Its light intensity apparently increases with age, and is relatively less rich in the short, but richer in the long waves, than that from the acetylene flame, but its radiation rapidly becomes more like that from burning acetylene with increasing current strength. At current strengths below the rated normal value, the increase in intensity with increasing current strength is most marked in the long waves, and above this rated normal value of current strength the increase in intensity is most rapid in the short waves. At current strengths below the rated normal value the Nernst lamp is relatively less rich in short waves than the flame of the Hefner lamp, while above this current strength the opposite is true. At rated normal current strengths, or slightly above this, the colour of the Nernst lamp radiation is very similar to that of the Hefner lamp. The luminous radiation from the Nernst lamp corresponds very closely to that from incandescent calcium.

Deposition of Zinc.—In a paper on this subject read before the American Chemical Society, Dr. E. H. Patten describes some experiments made in electrolysing a saturated solution of zinc chloride in acetone between platinum electrodes three square centimetres in area, and approximately 0·7cm. apart, at 25deg. C. The current E.M.F. curve shows a decomposition point at two volts. A large residual current was observed. At 0·9 volt 0·0014 ampere passed, remaining fairly steady. At 1·02 volts 0·0019 ampere steady current passed, no gas bubbles being visible on either electrode. A battery point was found at 1·27 volts during the first stage of electrolysis, but after electrolysing perhaps one half hour the battery point obtained was 1·32 volts. During the whole course of this electrolysis no gas bubbles appeared at either electrode.

Digitized by Google

Chloroform, chlor-acetone, or other alkyl chloride were formed at the anode, and a smooth, compact coating of zinc was deposited upon the cathode. The zinc may be deposited steadily with a current density of 2·25 amperes per square foot. The experimenter also used a current density as high as 40 amperes per square foot, but the zinc trees out from the edges of the cathode in long streamers; nevertheless, the zinc deposited upon the main portion of the cathode is smooth and dense. As one of the chief difficulties in the electrodeposition of zinc consists in avoiding the liberation of hydrogen upon the cathode and a consequent pitting of the coat, the availability of a solution such as this, where no hydrogen or other gas is liberated at a high current density, will readily be seen. The thickness to which zinc may be deposited from this solution has not as yet been determined. The author proposes to investigate this further, and also to make careful analysis of the zinc obtained from this solution. The difficulty of obtaining chemically pure zinc certainly warrants such an investigation. The apparent lack of carbonisation of the salt, the lack of gas formation at the cathode, and the comparatively complete fixation of the chlorine at the anode, taken together, look promising.

Porous Diaphragm for Electrolytic Cells.—For many electrolytic operations it is necessary to hold the anodic and cathodic departments separated by porous diaphragms in order to prevent any reaction between the anodic and cathodic products of electrolysis, as such reactions mean decreased efficiency of operation. A patent described in detail in the *Electrical World* has been granted to Dr. E. A. Byrnes for improvements in the construction of such porous diaphragms. Many substances of high specific conductivity afford a body of low conductivity when finely divided; such a poorly-conducting granular body may be used as diaphragm, the size of the grains depending on the requisite porosity and conductivity of the diaphragm. These grains may either be mixed with an inert binder (like silicate of magnesium or calcium or ferrous hydrate) and moulded into a self-supporting diaphragm, or they may be used without binder, and are then enclosed between perforated metal sheets, if used for a vertical diaphragm. For cells with a horizontal cathodic surface a floating diaphragm may be employed. For the electrolysis of brine with a mercury cathode, the inventor places a sheet of amalgamated copper or iron wire gauze upon the mercury, and upon this wire gauze rests the granular diaphragm. In the same way in the electrolysis of molten sodium chlorine with a molten lead cathode, the latter is covered with a wire gauze on which the diaphragm rests. The diaphragm material should be inert toward the electrolyte and its products. For the electrolysis of alkali chlorides and nitrates, whether in solution or fused, diaphragms of magnetite or ferro-ferric oxide are suitable; ilmenite or chromite are also available. Broken glass or porcelain are suitable in aqueous electrolytes. For the electrolysis of molten sodium chloride with a molten lead cathode, a diaphragm of broken magnetite is suitable. For the recovery of metallic sodium from any of its molten compounds, the inventor proposes to fill a metallic vessel which serves as anode nearly entirely with granular material, a well being maintained at the top by means of a perforated cup placed around the cathode. The sodium rises and floats upon the surface of the electrolyte in the cathode well.

Technical Instruction in London.—Dr. Chas. V. Drysdale has some interesting remarks to offer on the competition for intermediate county scholarships in London which took place recently. Dr. Drysdale is the examiner under the London Technical Education Board in heat and light and in electricity and magnetism. As regards the former subjects the work of the candidates is regarded by him as about up to the average, although the work in heat was more satisfactory than that in light. Few, for instance, had distinct ideas of the nature of curvature, and the majority of the candidates were utterly unable to give the reason for the constancy of the ratio of the sines. An improvement was shown, however, in accuracy of photometric work, several of the candidates making satisfactory use of the spectrometer. We are glad to read that the quality of the work in electricity and magnetism has made a distinct improvement, the candidates showing more knowledge both of practical matters and of the construction of electrical measuring instruments. It may be gathered from the following remarks, however, that the evils of the text-book have fallen upon many of the candidates. Great weakness was shown by the candidates in last year's examination in describing instrument details, and although a very gratifying improvement is shown this year there is room for much more, many of the descriptions given, though fairly correct, being obviously the result of blackboard drawing or of text-book reading rather than of practical acquaintance with the instruments. The magnetic work was not so satisfactory as the electrical, and in electrostatics the answers in nearly all cases were rigidly on the lines of the most elementary text-books. One candidate only, a girl, described satisfactorily an electrostatic voltmeter, the description in this case being particularly good. The practical work was done much better than last year, some of the candidates being able to use commercial forms of Wheastone bridge, reflecting galvanometers, etc. In many cases it was obvious, however, that although the experiments were fairly well done, the candidates had never before performed the experiments set. The candidates in most cases showed very considerable aptitude for their work, and were worthy of having had better facilities in their practical instruction.

Critical Speed of Steam-Turbines.—In a brief communication to the *Street Railway Journal*, Franz zur Nedden, writing from Berlin, draws attention to the great importance of a method of quickly finding the critical speed value of steam-turbines up to a certain degree. This method consists in the exact balancing of the rotors, and he gives the following requirements for balancing as working satisfactorily: (1) that the complete mounted rotor should be supported at the journal bearings, and not at any other points when being balanced; (2) that the rotor be supported at the bearings on cylindrical surfaces, which are cut with absolute exactness in order that there shall be no unevenness of surfaces which would introduce errors when testing; (3) that the shaft be revolved between stationary points; and (4) that the rails for the support of the testing apparatus be placed throughout their entire length on foundations which are free from vibration. By following these requirements it is possible to reduce the radius of gyration to 1/300mm. There is, however, a certain element of danger in the armatures of dynamos Assuming that the apparatus is mounted correctly, yet, owing to the great centrifugal force, the shifting of a winding now and then can hardly be avoided. This, of course, will shift the centre of gravity, which shifting may easily have important effects on the armature. As a matter of fact, in spite of the most careful selection of the proper running speed in comparison with the critical speed, nearly all wire-wound armatures will give trouble. This is particularly true with direct-current machines, which, in addition to an armature, also have a commutator as a rotating element. The following methods are suggested for safely running high-speed turbo-generators: (1) secure

Digitized by Google

greatest possible difference between the actual running speed and the critical speed; (2) use alternators in preference to direct-current machines whenever possible; or better still (3) use non-synchronous generators. This latter machine possesses the advantage of having an armature carrying absolutely no wire. In fact, this form permits the use of speeds up to 3,000 and 4,000 revolutions per minute. In the Moabit central station of the Berlin Electricity Works there has been running for several months a non-synchronous 1,800-h.p. turbo-generator using wattless current, and it has given no trouble in the direction mentioned.

Wireless Telegraphy at Sea. — Writing his impressions of the naval manœuvres, a naval correspondent on board H.M.S. "Good Hope" describes some trials which were made with the aeroplane or box-kite, invented by Mr. Cody, in connection with wireless telegraphy. The kite has been tried on land for this purpose on several occasions, but this was the first instance in which it had been tested on board a man-of-war. In shape the kite resembles a box, and is made of a material similar to silk alpaca. As the frame is made of bamboo the result is a singularly light and strong kite, capable of withstanding a great pressure of wind. In its connection with wireless telegraphy the kite takes up an aerial wire which is connected to the wireless telegraph instruments on the vessel. The recent trials abundantly proved that with the aid of these kites it is possible to establish communication at sea over far longer distances than if the aerial wires were suspended from the masts. For instance, the wire was carried up some 300ft. by the kite, and the "Good Hope" was able to exchange wireless messages a distance of 110 miles with the wireless telegraph station at Rame Head, off Plymouth. The average distance of communication between ship and shore by this means is, say, 60 or 70 miles, so that the use of the kite gave a considerable advantage. It may be added that in a short time the wireless system of telegraphy will be extended to all the large British warships; also that the Admiralty is about to construct a large wireless station on the east coast for establishing communication with the North Sea Fleet. It is amusing to see what the correspondent has to say with regard to the possibility of interception of wireless messages. Thus, he tells us that Vice-Admiral Sir Arthur Wilson during the recent manœuvres freely utilised wireless telegraphy for misleading the enemy's ships. He goes on: "This has become a well-recognised means of baffling a foe who tries to utilise this method of communicating news to consorts. Two ships out of sight may have just got into communication, though 50 or more miles apart, and then a foe, overhearing their preliminary calls to one another, will put his spoke in their wheels by sending out aimless messages, humorous or otherwise, or it may be merely a column from some newspaper. Anything suffices which will serve as body for messages. Waves are created and get mixed up with the legitimate signals from ship to ship of the enemy, and the instruments within signalling distance record merely a jumble of dots and dashes which have no rhyme or reason. This is called 'blocking,' and until it is rendered impracticable the wireless system will remain comparatively useless, if not actually dangerous, in time of war."

Motor Specification. — The following are a few clauses extracted from the specification for direct-current motors of the United States Navy Yard Department. They show what this department requires from its contractors, and it is to be noted that the temperature rises allowed are considerably above what is standard practice in this country. Thus 81deg. F. is the lowest rise specified, while armatures of enclosed machines are allowed 99deg. F. rise after six hours' run at full load. In other words, the U.S.A. Navy Yard will take smaller motors for a given nominal output than will ordinary contracting firms in England. The clauses most interesting to our readers are as follows: (4) Brushes are to be of carbon, and not to carry more than 35 amperes per square inch at full load. The brush-holder springs shall not be depended upon to carry current. In motors of 5 h.p. and above brush-holders are to be separately adjustable for tension without tools, and simultaneously adjustable for position. In motors below 5 h.p. these adjustments are not required. Brush-holders to be of such design that by very slight changes in the relative position of their parts the rotation of the armature may be in either direction with equal satisfaction; also the angle of the brush to the commutator not to change as the brush wears down. (7) Dielectric strength of insulation to be tested in accordance with the rules of the American Institute of Electrical Engineers. (8) Open motors must run from no load to full load; semi-enclosed motors from no load to 10 per cent. overload; and enclosed motors from no load to 25 per cent. overload, without sparking and without shifting the brushes. Motors to run at all rated loads and speeds without vibration and without undue noise. (9) Motors are to be tested at the works of the maker in the presence of an inspector, and are to run for a continuous period of six hours at full rated load, speed, and voltage without the temperature rise above the surrounding air exceeding the following limits for the different types of motors:

Part.	Open motors.	Semi-enclosed.	Entirely closed.
Field coils by resistance	50	55	55
Armature, commutator, and all other parts by thermometer ..	45	50	55

All rises are to be in Centigrade degrees. The temperature rise of the field coils is to be measured by the resistance method according to the rules of the American Institute of Electrical Engineers. All other temperatures are to be measured by thermometer. Temperature rise of bearing is in no case to exceed 40deg. Semi-enclosed and enclosed motors are to be run with all their covers on. During the six-hour heat run no adjustment of brushes, cleaning or dressing of the commutator, or similar attentions are to be performed on the motor, but after being once put in proper running conditions it must complete a satisfactory run without further attention. (10) Motors are to stand the following overloads:

Type.	Overload for one hour.	Overload for three minutes.
Open	25 per cent.	40 per cent.
Semi-enclosed ...	35 „	60 „
Enclosed	50 „	100 „

The one-hour overload is to be run without injurious sparking or heating of the commuator more that 15deg. C. above the allowed rise for full load for six hours, and may be started with the motor cold if desired. The three-minute overload is to be run without injurious heating, or flashing over or burning of the commutator or brushes, and is to be made within 45 minutes of the end of the six-hour heat run. (11) The full-load efficiencies of motors to be at least as follows:

Horse-power.	Open. Per cent.	Enclosed and semi-enclosed. Per cent.
2	78	75
5	83	80
10	86	84
15	87	85
25	89	87
40	90	88

COMBINED LIGHTING AND HEATING PLANT AT DRESDEN.

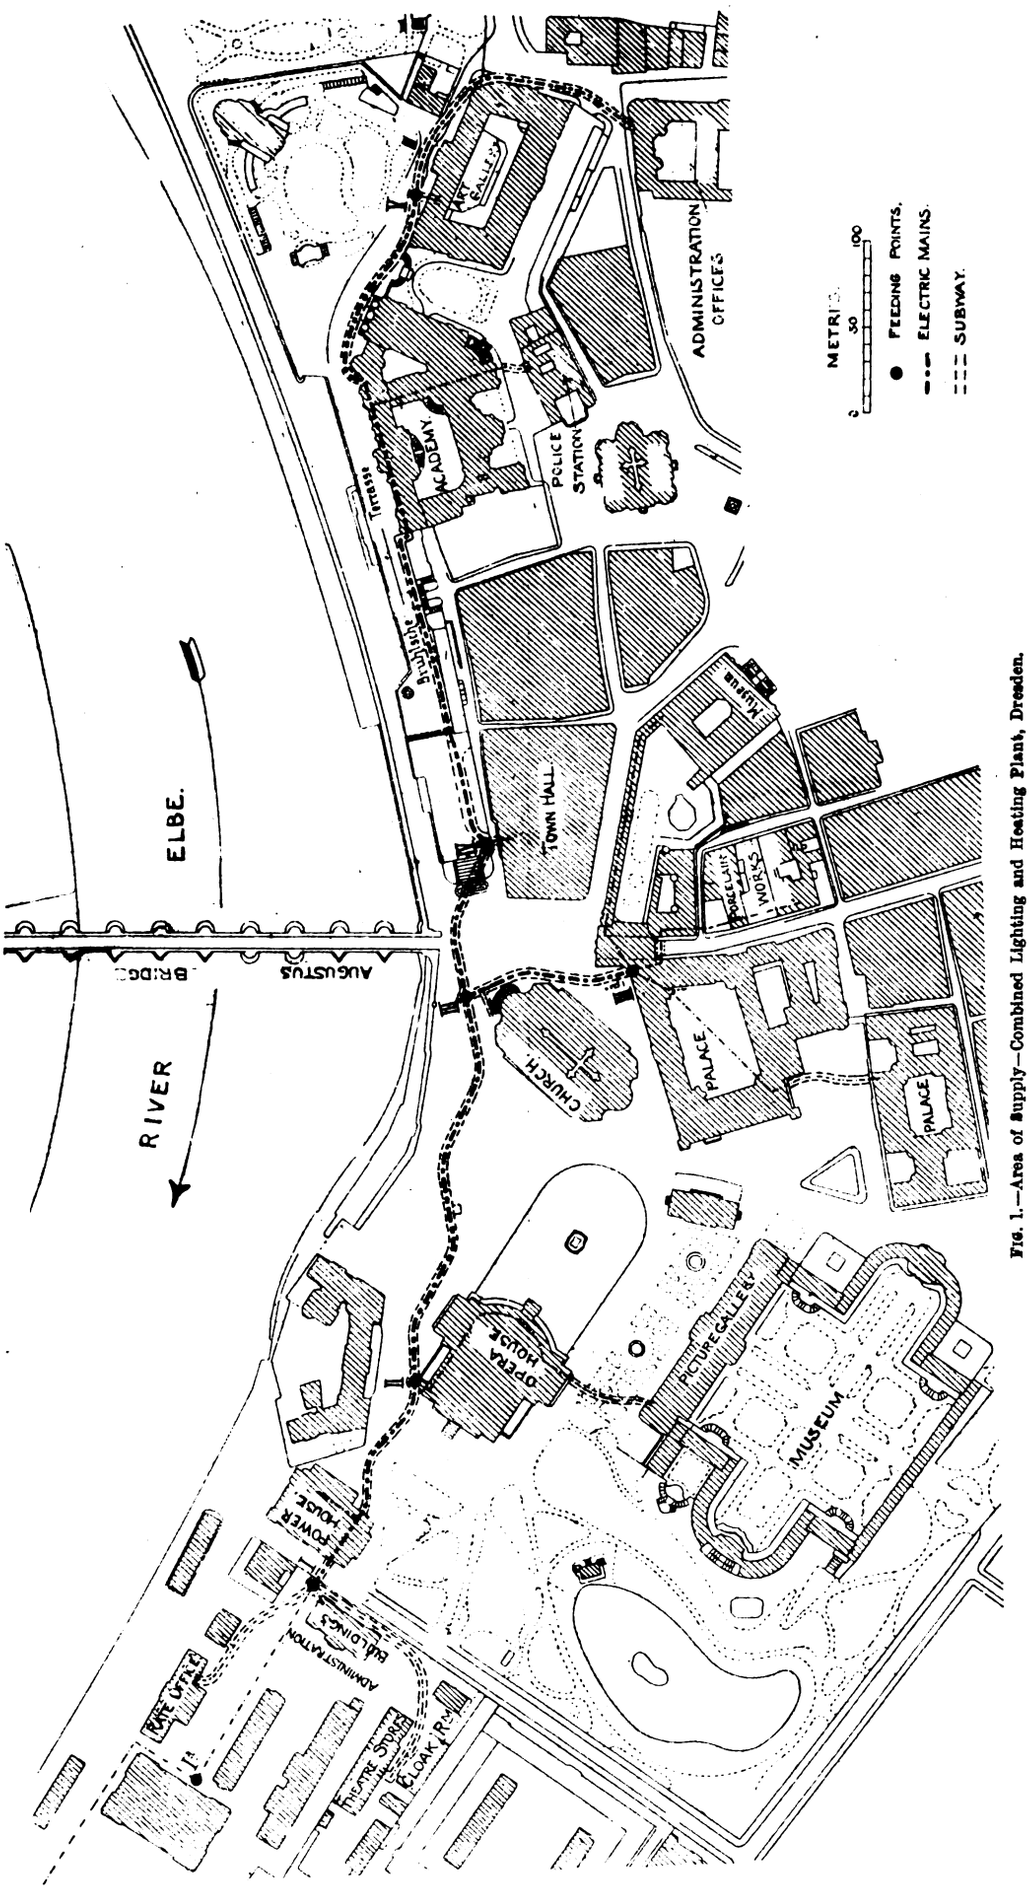

Fig. 1.—Area of Supply—Combined Lighting and Heating Plant, Dresden.

Those of our readers who went with the Institution of Electrical Engineers to Germany in 1901 will doubtless remember that one of the visits arranged in Dresden was to the central station designed to supply heat and light to the King's Palace and various public buildings in the vicinity. The station was then in process of completion, and full particulars were not available, the visitors having to content themselves with a hurried inspection of the

Digitized by Google

plant. However, details are now to hand, and we propose to briefly describe what was voted one of the most interesting installations viewed.

Both in regard to electricity supply and artificial heating by means of steam, the conditions pertaining to a central station combining a common boiler plant are favourable in proportion as the number of consumers is greater and the nearer they lie together. Moreover, the erection of a single power-house not only tends to simplicity and reliability in working, but the danger of fire is also very much lessened. In the case of an installation designed to supply electricity principally for lighting purposes, while heat is required for warming rooms in permanent use, then the erection of a central power-house to serve both supplies offers special advantages. The greatest demand on the heating apparatus occurs in the early morning, when the rooms which have cooled overnight have to be brought up to the normal temperature. When this has been attained, the heat units required to maintain that temperature are found by experience to gradually dwindle until they represent a comparatively small amount. Consequently, during the evening hours the demand on the central plant is inconsiderable on this count. The reverse is the case, however, with the electricity supply, since the demand for light is by far the greatest during the late afternoon and evening hours. Hence, during the morning hours the boilers in the power-house are called upon to furnish steam principally for heating purposes, while later in the day they supply power for driving the steam dynamos which generate the lighting current. In connection with such an installation, it is advisable, as in the majority of cases where a purely lighting load has to be dealt with, to instal a battery of accumulators which can be charged during the day or over-night, and to adopt the continuous-current system of supply. In this manner we obtain a good load factor for our boilers, hence economical conditions of working. A further advantage especially affecting public plants consists in that the electric mains may be run in the subways provided for the steam mains. This arrangement enable the use of bare copper instead of conductors of the costly insulated type. The whole of the above conditions existed in respect to the installation with which we are now concerned. On the left bank of the Elbe, on either side of the Augustus Bridge, there are situated, besides the Royal palace, numerous Government and municipal buildings to be provided with heat and light, the line extending a distance of about one mile (see Fig. 1). When the central plant was erected some of these buildings were new, while others were equipped with heating apparatus which had become for the most part obsolete. The opera house, for example, contained no fewer than 24 separate boiler plants. The abolishment of these has incidentally effected a considerable reduction in the premium for fire insurance. But that is of small moment compared with the extra security obtained in respect to the art treasures and collections housed in the Royal palace, museums, and picture galleries within the area of supply, since many of these are of incalculable value.

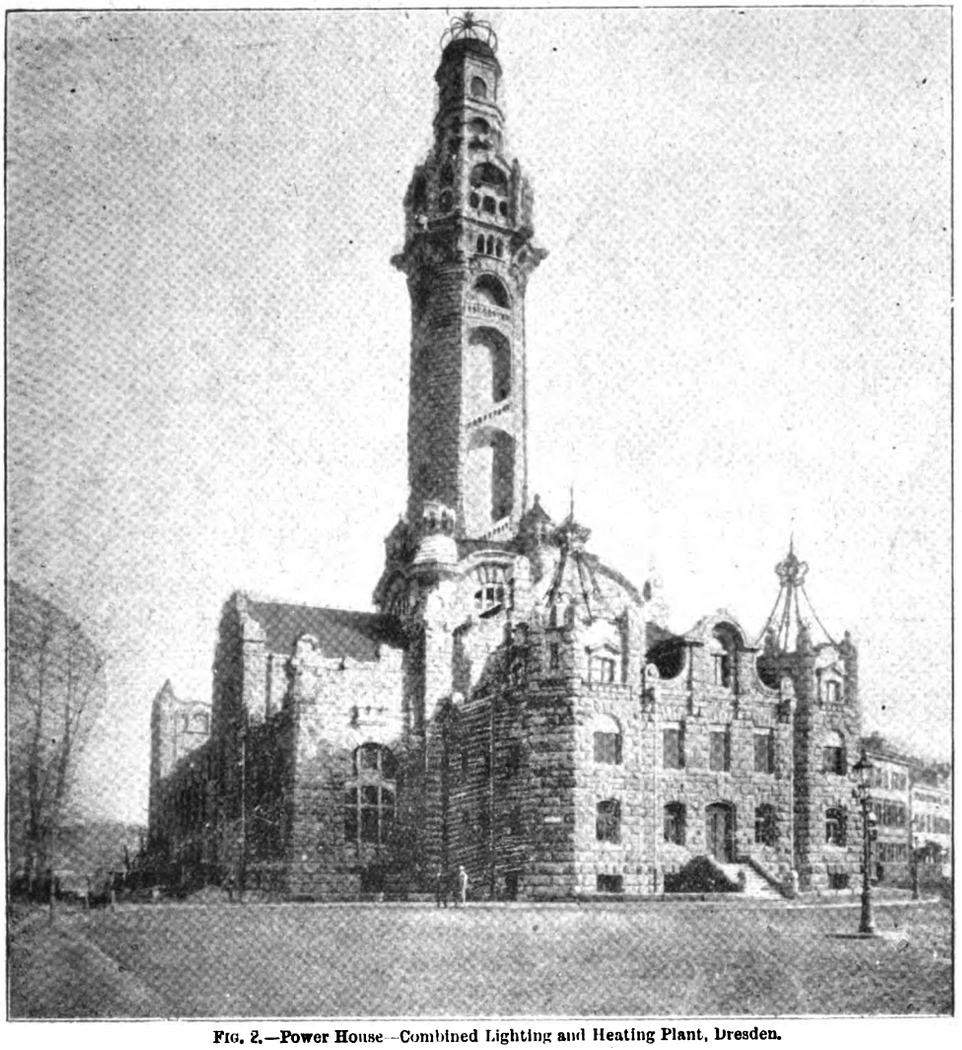

FIG. 2.—Power House—Combined Lighting and Heating Plant, Dresden.

The boilers and steam-pipes were supplied by Messrs. Rietschel and Henneberg, Dresden, while the Allgemeine Elektricitäts-Gesellschaft, Berlin, were responsible for the electrical work, with the exception of two steam dynamos, the battery of accumulators, and the main switchboard in the engine-room, which were supplied by the Elektricitätswerken vorm. O. L. Kummer and Co., Dresden. As regards the site of the power-house, it was essential that this should be as near as possible to the buildings to be supplied and convenient for coaling, etc. A suitable position was found off the opera house square, but having regard to the high architectural merit of the neighbouring buildings it was necessary that the design of the power-house should be carefully adapted. The result is seen in Fig. 2 herewith,

Digitized by Google

the architectural treatment of the chimney shaft being an especially noteworthy feature.

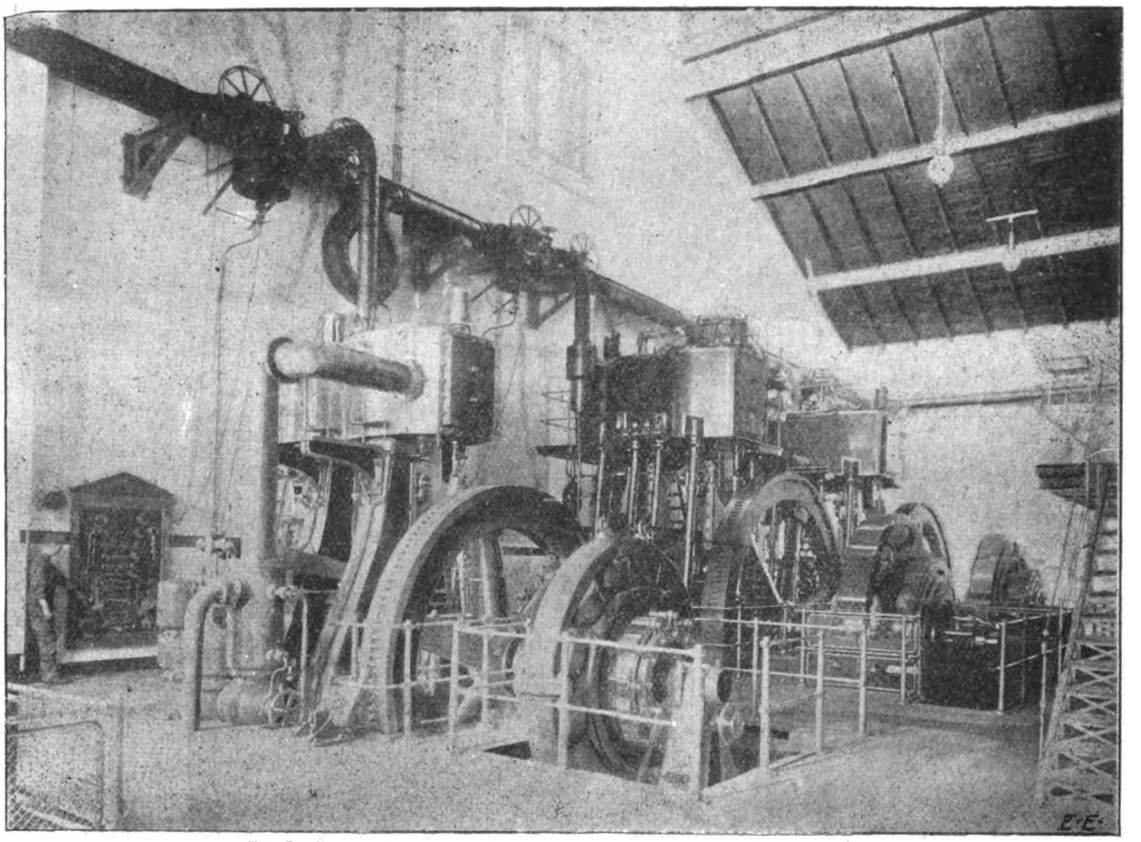

FIG. 3.—Electric Generators—Combined Lighting and Heating Plant, Dresden.

The determination of the most advantageous steam pressure is of primary importance in connection with heat transmission. In this case, having regard to the already existing installations of heating apparatus, it was found

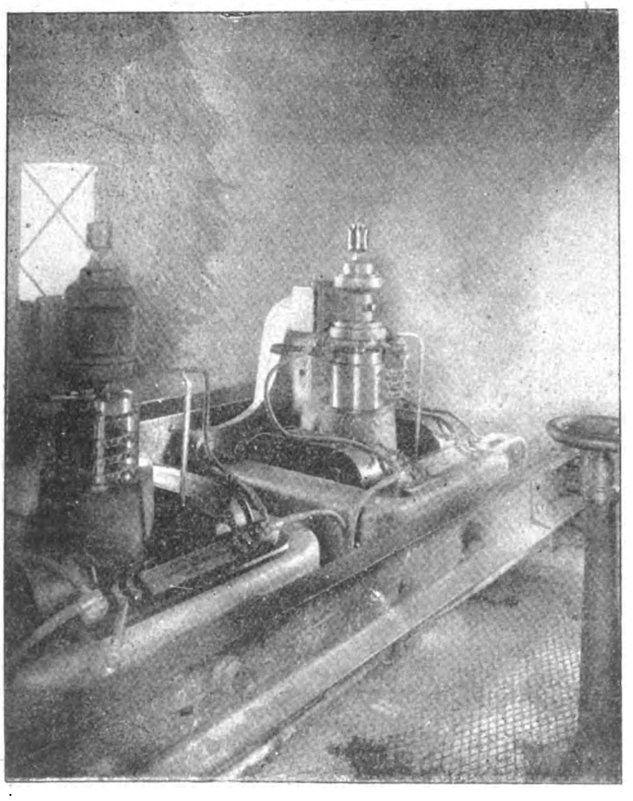

FIG. 4.—Electrically-Driven Centrifugal Pumps—Combined Lighting and Heating Plant, Dresden.

that a pressure of 28·5lb. per square inch would be best adapted for the supply in the buildings themselves. For the transmission of the steam it was, of course, necessary to employ a much higher pressure, since the diameter of the piping used is governed by the pressure, being smaller as the pressure is greater, and the loss of heat through condensation correspondingly less. It is not practicable, however, to increase the pressure beyond a certain limit, determined by the danger of leakage and fractured pipes. In Dresden the main pipeway lies under a very busy thoroughfare, so that an initial excess pressure of

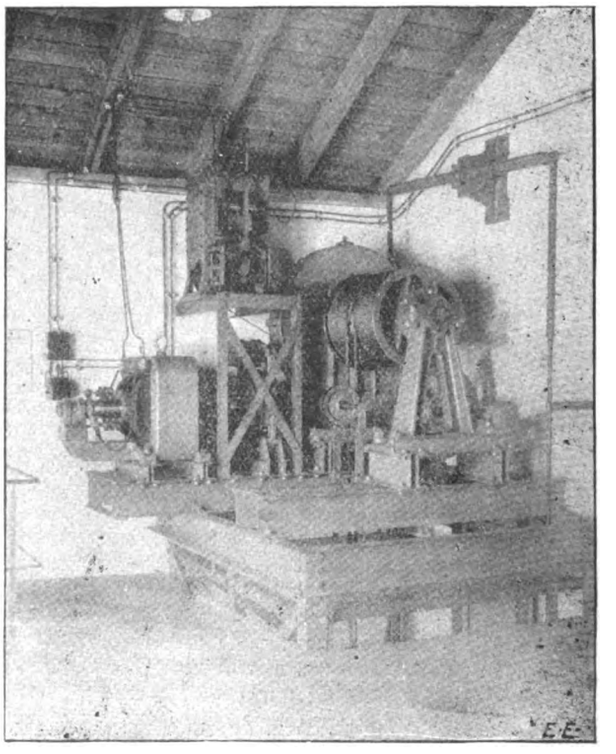

FIG. 5.—Motor-Driven Coal Hoist—Combined Lighting and Heating Plant, Dresden.

85lb. per square inch was adopted, provision being made to increase this to 107lb. per square inch as required. The latter provision will enable further connections to be made to the supply, and also constitutes a certain reserve. For,

Digitized by Google

in order to ensure freedom from interruption in the supply, two pipes of equal diameter connected in parallel are employed for the main transmission. Should it be found necessary to temporarily cut one of these pipes off at any time, the efficiency of the other may be increased by raising the steam pressure. Generally speaking, it is during the winter months only that steam is required for heating purposes. But the opera house requires a supply also in the summer, and this is provided for by a special main of correspondingly small diameter, laid direct from the boiler-house. Various means are adopted to compensate the expansion of the pipe mains through heat. To this end, for example, the subway is not straight, but follows a slightly winding course (see Fig. 1) so that the pipes, which rest on roller bearings supported by bracket arms, have room for side play.

this battery, and the balancer previously mentioned at 2 × 110 volts. The current from the dynamos and accumulators is conveyed to the main switchboard in the engine-room. From this board feeders are run to the lighting network; also leads to a motor board erected apart. Through the latter the motors driving the different auxiliary machines in connection with the power plant are supplied. These include two 17-h.p. motors, having vertical shafts, which drive two centrifugal pumps serving the condensers; also a 13-h.p. motor geared to a boiler feed pump. The first-mentioned pumps (Fig. 4) are installed in a special house on the Elbe. Two motors, each of 10 h.p. (Fig. 5), drive the two coal hoists which serve the mechanical stokers in the boiler-house. A crane which is used to unload coal from barges is equipped with two motors, one of 7·5 h.p. for lifting and one of 2 h.p. for

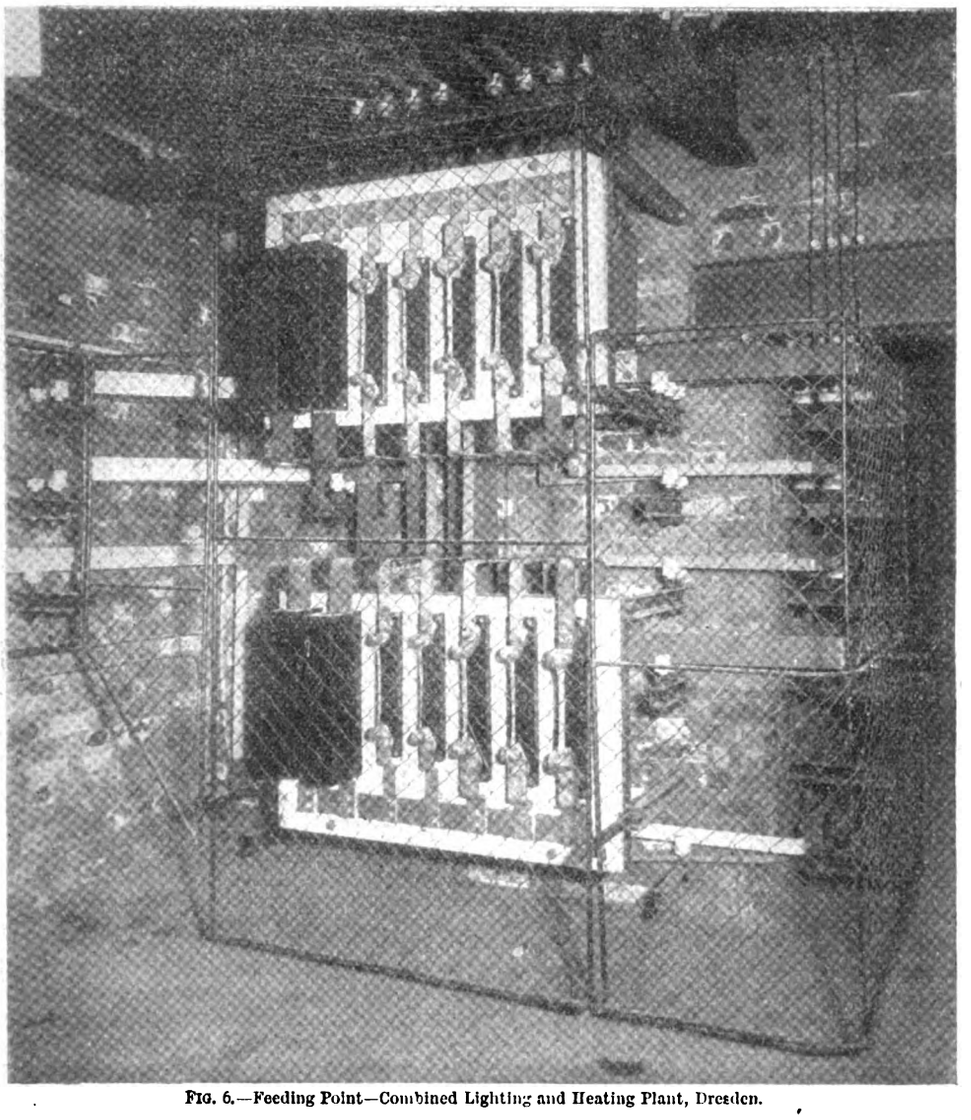

FIG. 6.—Feeding Point—Combined Lighting and Heating Plant, Dresden.

The boiler-house contains 10 boilers—including the necessary reserve—each having 2,151 square feet of heating surface. These boilers, as previously mentioned, supply steam also to the three continuous-current steam dynamos, Fig. 3 comprising the electric lighting plant. Two of these dynamos have a normal output of 260 kw. each and a maximum output of 360 kw. at 220 volts terminal pressure, while the third yields 130 kw. normal and 175 kw. maximum output at the same terminal pressure. A balancer is further provided for the purposes of the three-wire system of distribution adopted. To ensure absolute reliability of the supply, which is especially necessary in the case of the opera house, a battery of accumulators has also been installed. This battery consists of two parts, each of 2 × 132 cells, coupled in parallel. The capacity of each part is 1,080 ampere-hours, the charging current 360 amperes, and the discharging current likewise 360 amperes. The three-wire system of distribution is worked in conjunction with turning. Numerous smaller motors are employed about the station for driving machine tools, etc.

With reference to the electrical transmission line, the feeders are run from the switchboard to a ring main, from which the distributing leads branch. There are in all six feeders and the same number of feeding points. Owing to the elongated form of the area supplied, the ring main consists of two conductors for each outer of the three-wire system connected together at either end and lying close together. A single conductor serves as the neutral wire. Hence at each point of the system the ring is made up of five conductors—*i.e.*, two + outers, two − outers, and a neutral conductor. The two feeders taken to each feeding point are each connected to the two outer conductors of like sign. The negative conductor is doubly earthed at each feeding point. The pressure loss in the mains is regulated by means of resistances connected in series with the feeders at the switchboard. The maximum loss of pressure which can occur in the feeders amounts to 10 per cent.;

Digitized by Google

between two points in the ring at any load, 2 per cent.; and in the distributing network, 2 per cent.

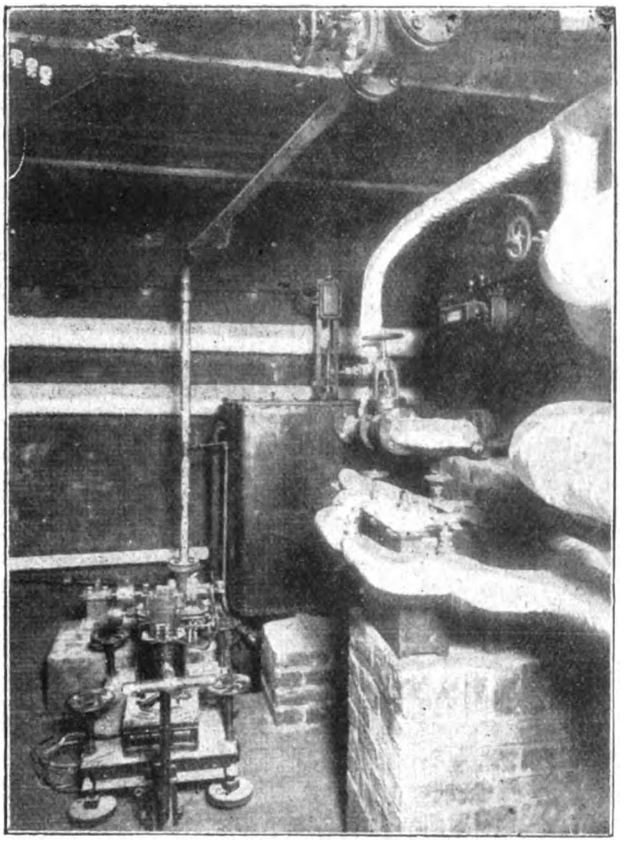

FIG. 7.—Condensation Water Pump driven by Portable Electric Motor—Combined Lighting and Heating Plant, Dresden.

For the most part the conductors are arranged in the subway on the wall opposite the steam mains. They rest on porcelain insulators carried on [iron supports built

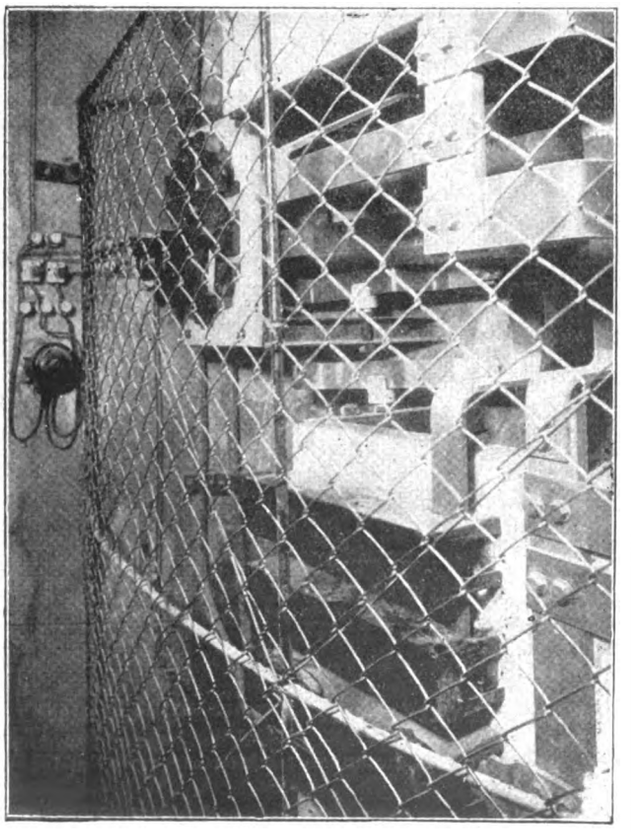

FIG. 8.—Distributing Point—Combined Lighting and Heating Plant, Dresden.

into the wall. The conductors themselves are composed chiefly of bare copper cables, which have proved satisfactory in every respect. Conductors of like sign are grouped together as far as possible, their polarity and purpose being clearly indicated by different colours. The conductors are fenced in by means of wire netting arranged in portable sections.

At the feeding points, which serve at the same time as distributing centres, the stranded cables give place to solid bars of copper (Fig. 6). Referring back to Fig. 1, it will be seen that the distance between the first and second feeding points is considerable. For this reason an emergency exit from the subway has been provided in the opera house square. At this point the conductors are necessarily suspended from the roof of the subway, copper bars being also employed here. The distributing mains from the third feeding point run through a tributary subway, the first entrance into which is situated by the Catholic church. At this point a centrifugal pump (Fig. 7) is provided to remove the condensation water from the pipe system. This pump can be driven as required by means of a portable electric motor. Similar pumps are provided at different points throughout the system, all being actuated by the same motor, which can be easily drawn along the subway. The condensation water is

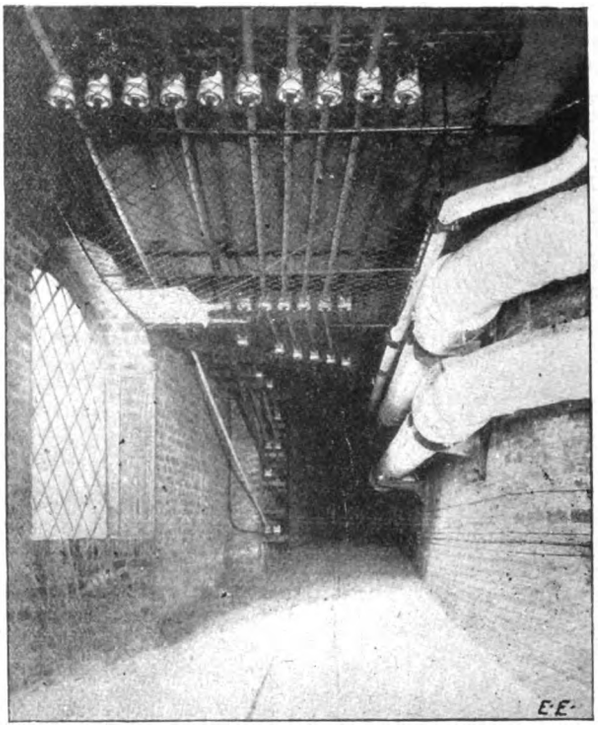

FIG. 9.—Arrangement of Steam Mains and Electric Cables at the Munzgasse Crossing—Combined Lighting and Heating Plant, Dresden.

returned to the boilers through a special pipe line. The above-mentioned tributary subway terminates in a special distributing centre (Fig. 8). A special reserve cable is laid underground to the Royal palace, so arranged that in case of failure in the supply from the subway it is automatically switched in at the third feeding point. A reserve cable is also provided for the opera house.

The arrangement of the steam-mains and electric cables at the Münzgasse crossing is shown in Fig. 9.

The further course of the subway may be traced on Fig. 1.

We are indebted to the Allgemeine Elektricitäts-Gesellschaft for the above particulars, as also for the loan of the photographs from which our illustrations of the installation are reproduced.

THE DESIGN OF EXTRA HIGH TENSION SWITCHGEARS.

BY W. E. WARRILOW.

(Continued from page 231.)

A somewhat similar switch, but depending for its action on the pull obtainable from electromagnets, is shown by Fig. 22, from which it will be noticeable that the arrange-

Digitized by Google

ment of the breaking tubes is similar to the foregoing, as also the mounting of the operating motions on the top of the brickwork chamber. Mounted at the top of each compartment are the main contacts, set in insulators, two for

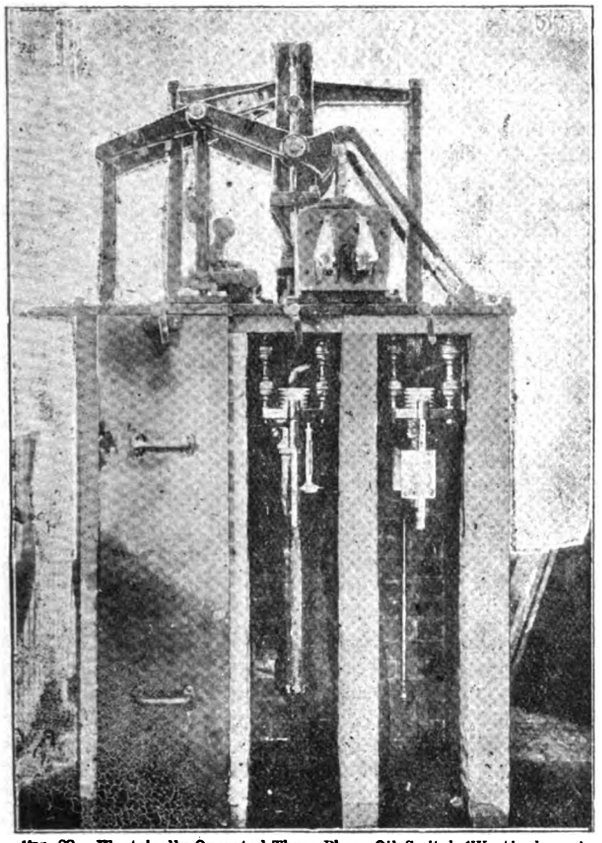

FIG. 22.—Electrically-Operated Three-Phase Oil Switch (Westinghouse).

each pole, these contacts being quite stationary. The circuit is closed by joining these two contacts with a U-shaped copper conductor connected to the operating mechanism above, and this moving conductor forms the "live" portion of the switch travelling in the oil tank.

by balancing springs, both springs and magnets being visible in the upper right-hand corner of the illustration. When the switch is closed, the system of levers is automatically locked by a toggle joint (shown at the left hand of the operating mechanism). For opening the circuit, a tripping magnet is energised, which releases the toggle, and the cross-bar, carrying the moving contacts in the oil-tanks, drops quickly under the influence of gravity assisted by a powerful spring. Any arcing or burning at the main contacts is taken up on a removable plug set in the fixed contacts, this plug engaging with a hole in the moving conductors and leaving them last.

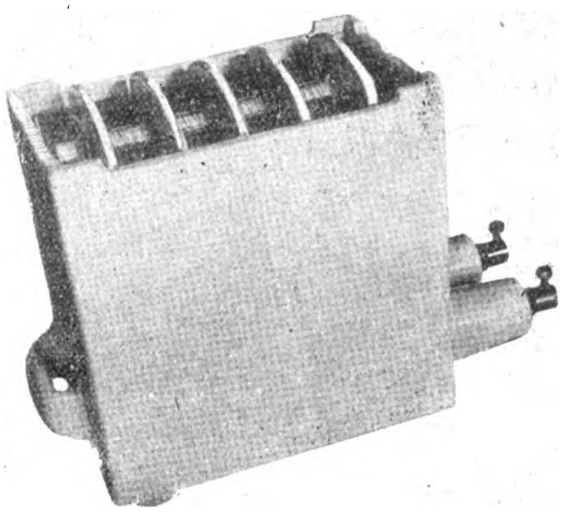

FIG. 23A.—Complete Multi Oil Fuse, showing fuse wires in position (Ferranti).

The operating magnets can be energised from any direct-current source, either in the shape of exciters or storage battery, and, if required, the switch can be actuated by hand without disturbing any portion of the mechanism. The oil containers are constructed of sheet metal lined with an insulating cement, this latter being moulded to fit round the terminals and contact piece. Sufficient room is left for the free movement of the coupling rod, and the amount of oil required is reduced to a minimum. A complete and accurate adjustment of the contacts can be

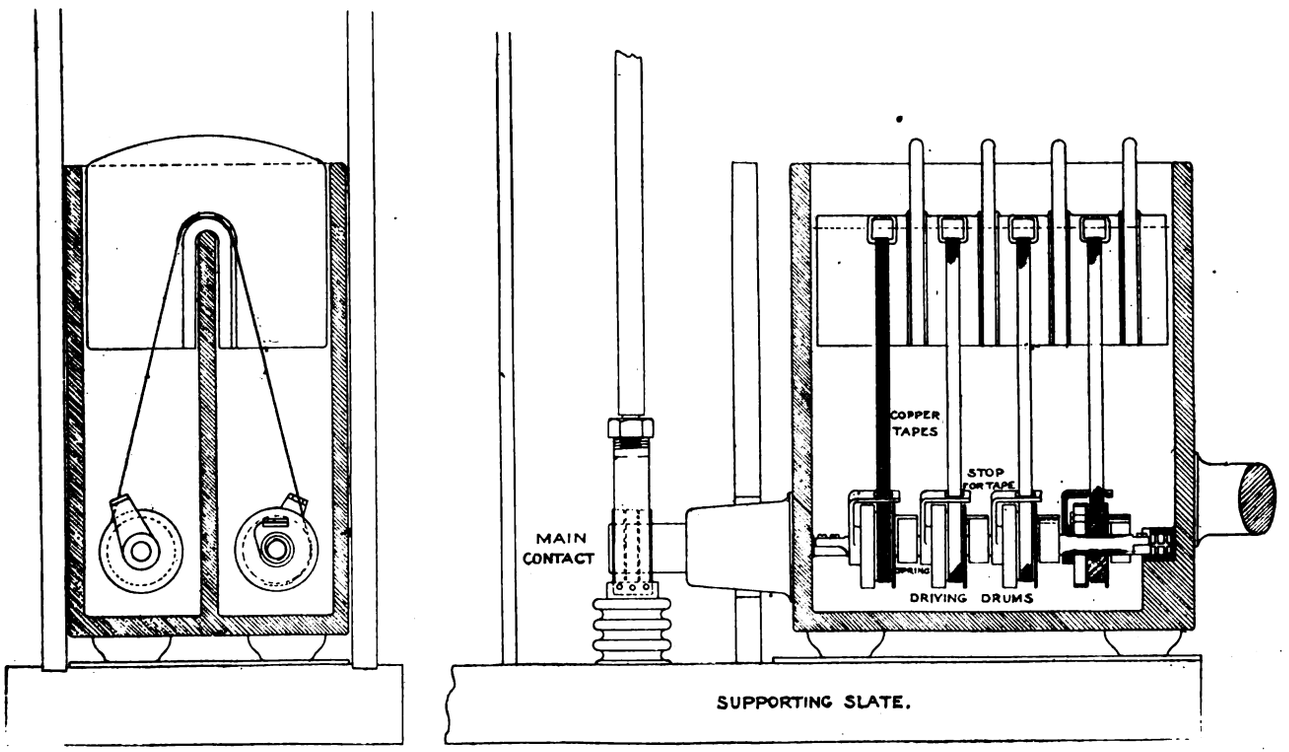

FIG. 23.—Multi Oil Break Fuse (Ferranti).

The couplers for each pole are fastened to a common cross-bar extending the entire width of the masonry compartment, the bar itself bolting to a lever system having a vertical up and down motion. The electromagnets raise the cross-bar, which is aided through the first part of the travel carried out before the oil-tubes are raised into position, and at any time upon lowering these the moving parts can be closely inspected. The automatic opening of the circuit breaker is effected by a polyphase overload relay connected to the secondaries of current transformers in the

Digitized by Google

main circuits, the relay being shown in the photo directly above the dividing wall between the oil-tubes. It comprises two sectors swinging between the poles of an alternating-current electromagnet, and part of each pole is surrounded by a short-circuited strip of copper which tends to retard the magnetic flux and produce a moving field. On the principle of the induction motor, the swinging sectors are acted upon, and, following the movements of the field, they close the tripping magnet circuit by bringing two contacts together. Controlling and indicating devices, consisting of a switch, an indicator, and a lamp, are suitably mounted on the main board. The switch is of the drum type, with three positions—"closed," "off," and "open"—and it will remain in the last two of itself. If turned to the "closed" position it will go back to "off" position when the handle is freed, but in the "off" position it closes the control circuit; and if the main switch opens through the medium of the automatic devices, the indicating lamp will light up to attract the attendant's notice. When the oil-switch is opened by the operator placing the control switch in the "open" position, the lamp does not glow. The indicating mechanism comprises an electromagnet which attracts an armature carrying a disc and pointer, showing at a glance the "open" or "closed" positions of the oil switch. A switch of this description will successfully open a circuit of 600 amperes capacity at a pressure of 33,000 volts.

The last form of gear to be described, but by no means the least interesting, is that assembled on what has come to be known as the "cellular" or pigeon-hole plan. This method of construction calls for a distinct departure from the methods of other makers, in that all the parts of the board must be designed to take their respective places in the panels provided for their reception. The construction of the frame is too well known to need a detailed description here, but it is sufficient to state that the features which have made this type of board so prominent for high pressures have been, as much as possible, retained in the equipments got out for the control of extra high pressures. Considerable ingenuity has been displayed in the design of the fuses, switches, and ammeters of the gear, and they merit some fuller description if space permitted. The chief points of interest can, however, be dealt with here, and will serve to show that even extra-high potentials can be manipulated from gears which take up little room. In rupturing the circuit, either with switch or fuse, the breaks in each case are oil quenched; in the switch they are actually under oil, while in the fuse they are above, but plunge quickly down into the oil. Fig. 23 is a sectional illustration of the fuse, and reference to this will make its action quite clear. The oil container is of porcelain, and comprises a large box divided down the centre by a rib reaching almost to the top of the pot, and provided with projecting lugs at the back for the main contacts. A handle at the front also makes provision for the ready withdrawal of the fuse from its panel. The device combines three or more fuses in parallel, each of which is made up of two drums, mounted on a spindle fitted at the bottom of the cells formed by the partition in the box. Each drum contains a powerful clock-spring, fastened at one end to the spindle and at the other to the drum. A length of flexible copper tape reaching to the top of the dividing bridge is also secured to each drum, and when the springs wind up the tape is coiled round the drum, a guide being mounted on the spindle to prevent fouling. This method of construction gives a pair of operating drums and tapes to each fuse, and allows of any number of pairs being assembled in accordance with the capacity of the circuit to be opened. This particular type of oil-break fuse is intended for mounting in position apart from the main gear or underneath the operating gallery, to ensure head room above the pot when the fuse blows. Experiment has shown that a lid is not safe, and that the gases liberated when the arc occurs can only be dispersed with the best result by allowing them a free vertical passage to the air. A porcelain guard separates each fuse from its neighbour, and these guards slip into grooves in a removable bridge resting on the top of the rib dividing the pot. This precaution has been taken to enable the porcelain to be replaced should excessive burning take place on the rupturing of the fuse. The wires forming the fuse are soldered to the ends of the copper tape, which is fitted with a ring for this purpose, and when secure they are kept in tension by the action of the springs. The passage of an excess current causes fusion of all the wires which are immediately drawn under the oil and the arc takes place at one pair only, though not always at the same pair. When putting in new fuses, the ends of the copper tapes are hooked up out of the oil and held in position while the wires are soldered in place, the entire operation being easily performed by a handy switchman. The main contacts project from the back of the porcelain case, and plug into suitable clip connections on the main board provided for the purpose, thus enabling one fuse to be replaced by another in a short time.

(To be continued.)

RADIUM AND OTHER RADIOACTIVE SUBSTANCES WITH A CONSIDERATION OF PHOSPHORESCENT AND FLUORESCENT SUBSTANCES. THE PROPERTIES AND APPLICATIONS OF SELENIUM AND THE TREATMENT OF DISEASE BY THE ULTRA-VIOLET LIGHT.*

BY WILLIAM J. HAMMER.

(Continued from page 235.)

While various theories have been advanced to account for the phenomena of radium, there remain many things which have not been satisfactorily accounted for; and perhaps the subject which has been most widely discussed is the loss in weight of radioactive substances. At the British Association meeting last summer, Prof. J. J. Thomson is reported to have stated that if a square centimetre of surface were covered with pure radium, it would only lose in weight one-thousandth of a milligramme in a million years. This is in accordance with the previous statements made by Becquerel. Later in the year, A. Heydweiller, of the Royal University, Munster, Germany, stated that he had been testing a sample of De Haën's preparation of radium, and found that it lost in weight two one-hundredths of a milligramme per day for 50 days, and a whole milligramme in that period. (*Phys. Zeit.*, Oct. 15, 1902.) The great discrepancy in the statements on this important subject led the writer to enter into correspondence with Profs. J. J. Thomson, Henri Becquerel, Lord Kelvin, Sir William Crookes, P. Curie, and A. Heydweiller, which resulted in the following expression of views. Prof. Thomson was inclined to think that from the magnitude of loss found by Heydweiller, it must be due to some secondary effect, and he stated that he could not speak with certainty without a greater knowledge of the details of the experiments. As accounting for the results he, however, drew attention to the well-known coloration of glass by radium, by remarking, "One point, however, that ought to be attended to in these experiments is the effect of the radiation from radium on glass. Glass, as is well known, gets deeply coloured when in contact with radium. It seems to me possible that the glass might be charged right through. If this were the case, it is possible that reactions might occur between the glass and the air, producing volatile substances and a loss of weight. I only throw this out with hesitation, for as I said before, I am not familiar with the details of the experiments." Prof. Becquerel informed the writer that he knew nothing reliable regarding the experiments of Heydweiller, and called attention to his original paper on this subject which appeared in the *Comptes Rendus* of March 26, 1900, adding, "I believe I am the first to have published an estimate in this way which could only result from my own experiments. The loss of one milligramme per square centimetre require 1,000 million years. This statement refers only to the part of the deviable portion of the radiation to which measurements were applied; but this is only a part of the total loss.

*A lecture delivered at a meeting of the American Institute of Electrical Engineers and the American Electrochemical Society, New York, April 17, 1903.

Digitized by Google

The deviable radiations comprise rays ranging from 10^9cm. and $3{\cdot}10^{10}$cm. Besides, there is also all the non-deviable portion, either penetrating or absorbing, which corresponds to a notable loss of energy; and in addition, if the emanation is of material importance, which seems quite probable, the loss on this account would be a thousand times greater. These estimates are but theoretical, for it is probable that at least a portion of the mass calculated or estimated as material is apparent and corresponds to the effects of induction."

In response to an expression of view from Sir William Crookes on a theory to satisfactorily account for the phenomena of radioactive substances, he wrote as follows:

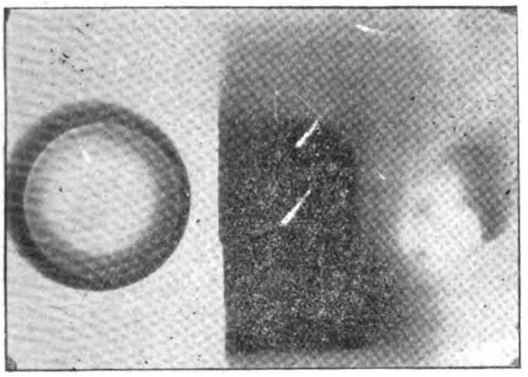

FIG. 6.—Radiograph made by Radium of a Disc for Testing Radioactivity, a Block of Rock-salt and a Lump of Pitch-blende.

"You will find them fully given in my address to the British Association at their Bristol meeting in 1898. I have not seen any special reason to alter the views there propounded"; and in writing on the subject of Heydweiller's experiments, Prof. Crookes says, "I do not think the experiments of Heydweiller have been corroborated by other observers; and there are many sources of error in his experiments which I should like to see discussed before giving credence to it. Personally, I find no loss of weight in a rich sample of radium compound during continuous weighings extending over many months. I should be inclined to agree with Becquerel and J. J. Thomson." Lord Kelvin wrote that he was sorry not to have been

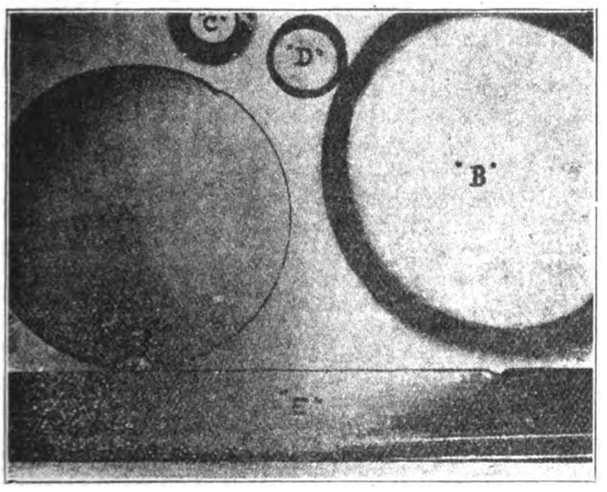

FIG. 7.—Radiographs of Various Types of Lenses made by Radium

able to make any experiments on radioactive substances which could allow him to offer any opinion that would be helpful on the subject, and added, "What you tell me regarding radium, and your correspondence with Prof J. J. Thomson, is very interesting." On this point Prof. Curie recently wrote me as follows: "I never did believe in the exactness of Mr. Heydweiller's experiments, and I always thought he did not take care enough to avoid some source of errors. In fact, with a substance considerably stronger than his own, I only obtained a reduction in weight of one-tenth of a milligramme in four months for several decigrammes of substance, and as the tubes were used at the same time in several experiments, that loss of weight does not allow me to affirm that radium is losing weight spontaneously. I believe, meanwhile, as does Mr. Heydweiller, that the question cannot be answered in any other than an experimental way, and that all speculative theories are of small interest. I have published my recent researches in the *Comptes Rendus d l'Academie des Sciences de Paris.*" As regards the published statements of Prof. Heydweiller's experiments, the writer can state that he is most reliably informed that a mishap

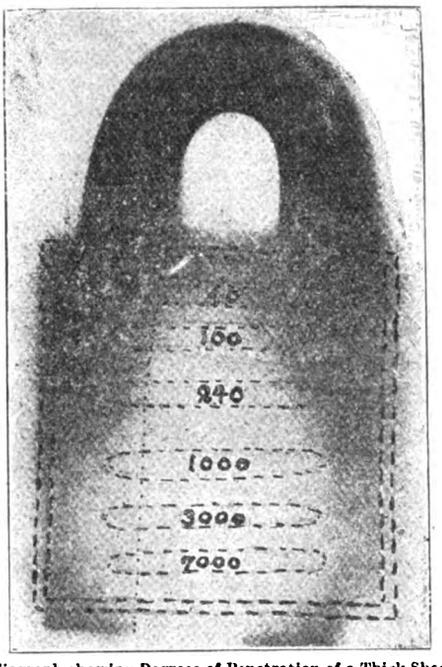

FIG. 8.—Radiograph showing Degrees of Penetration of a Thick Sheet of Lead and a Steel Magnet by Tubes of Radium of Different Radioactivities.

occurred during his experiments which resulted in one of the tubes becoming cracked, which was not observed until later, and that this practically nullified the results published, and, in fact, they have not been confirmed by subsequent tests; but, on the other hand, they tend to corroborate the experiments of Becquerel, and the statements made by him, Sir William Crookes, J. J. Thomson, and others. The writer is also informed that Prof. Heydweiller is continuing further experiments, the results of which will doubtless be published when his investigations are complete.

As bearing upon the coloration of glass already referred to, I hold in my hand a flask which I secured at the laboratory in Paris, which has contained radium, and has

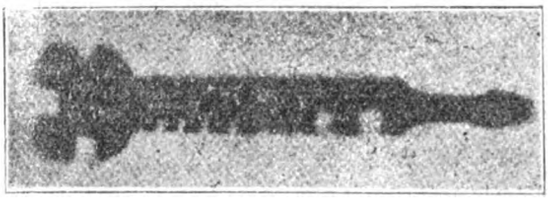

FIG. 9.—Radiograph of Steel Tool made by Radium acting through Two Thick X-Ray Plate Envelopes.

been most beautifully coloured a deep violet. I also have several tubes in which radium has been kept, which are similarly coloured, and in this connection I would call attention to the fact that X-ray tubes which have been in use for a considerable time become similarly coloured, forming another link between the Röntgen rays and radium rays. I also have here a tiny bulb of glass which is coloured a deep brown. I have seen only one other piece of glass coloured in this way, this being due to the difference in the chemical constituents of the glass (though in some cases the glass subsequently turns a violet colour). This is a duplicate of the tiny tube which Prof. Curie showed the writer, which contained between two and three one-hundredths of a gramme of chemically pure radium. It is interesting to note that the Becquerel rays induce activity which persists, whereas that excited by Röntgen rays ceases immediately on the removal of the rays. As illustrating the X-ray character of radium rays, I would call your attention to Fig. 6, in the centre of which is

Digitized by Google

shown a block of rock salt. The original sample was about 1in. thick, and was so transparent that a person's features might be seen through it. The rock salt is not only transparent to ordinary light, but also to ultra-violet light, whereas it is very opaque to X-rays.

Mrs. Hammer, appreciating the serious physiological effects of radium, has made the interesting suggestion that radium be kept in boxes made of rock salt; and the author is now having such a receptacle made. This might be even more satisfactory than a lead box. It would be interesting to note the change in the temperature of such a box or vial which so well intercepts the radium rays. The illustration referred to was made by placing the rock salt on a photograph plate with the radium some 5in. above it. To the right of the rock salt is shown a piece of

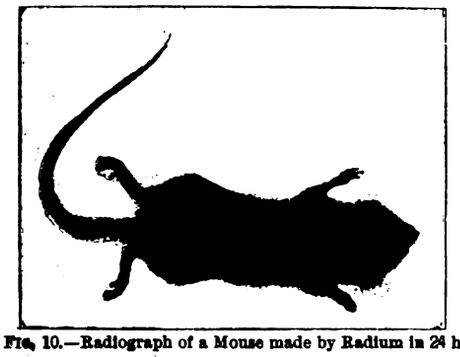

FIG. 10.—Radiograph of a Mouse made by Radium in 24 hours.

uraninite (pitchblende), from which radium is extracted; and you will note that not only has the mineral been photographed by the radium above it, but the radium has acted on the radioactive constituents of the pitchblende and caused this to affect the plate. The disc shown at the left of the cut is one made in Paris for the examination of radioactive substances. I have one of these here, and it consists of a rim of brass, enclosing a brass washer with a glass disc at the centre. The opposite face is covered with aluminium foil, and between the aluminium and the glass is placed some radium of 1,000 radioactivity. Substances which it is desired to examine are laid on this disc. It is, however, a rather crude piece of apparatus; but in the cut shown not only has the disc been photographed by the radium 5in. above it, but the radium inside of the disc has penetrated through the aluminium and fogged the plate.

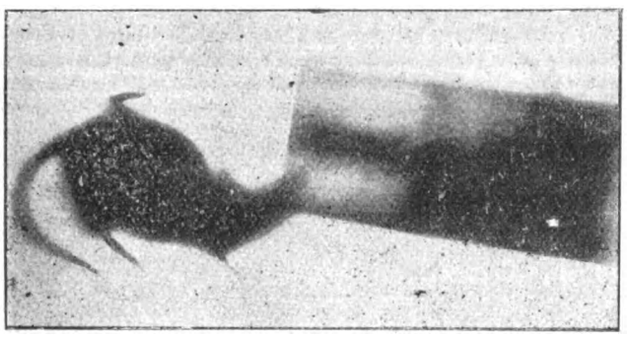

FIG. 11. Radiograph of Mouse caught in trap and exposed to Tube of Radium for three days. (Note transparency of wood, as with X-Rays.)

In Fig. 7 are shown some interesting effects of the radium rays in affecting a photograph negative after passing through lenses. The lenses, A and B, are plano-convex condensing lenses, one being placed with the flat surface down, and the other with the convex surface down. C is a double convex lens of crystal, D is a plano-convex lens of uranium glass, and E represents an ordinary glass prism. It is stated that radium rays cannot be reflected, refracted, or polarised. Those familiar with the phenomena of light will, I feel sure, be interested in the above photograph. In Fig. 8 is shown another illustration of the penetrative character of the rays, it being a thick lead box containing six tubes of radium, ranging from a radioactivity of 40 to 7,000; this box being laid upon a large steel magnet $\frac{3}{8}$in. thick. You will note the degree of penetration of both the lead and the steel varies according to the radioactivity of the radium in the various tubes. The exposure was made in 22 hours. Fig. 9 illustrates the penetration of the rays through black paper, the steel tool shown having been laid on the plate covered with two thicknesses of heavy black paper, such as used for wrapping X-ray plates, a single sheet of which is entirely impervious to light. The exposure was made in 24 hours. Fig. 10 shows a mouse which was radiographed in 24 hours by laying it directly on a plate, which was, as in the case of other experiments, placed in the bottom of a trunk, the trays being replaced and the trunk wrapped in three thick rugs, and kept in a dark room for 24 hours.

The radiograph of the mouse shown in Fig. 11 represents a mouse caught on another occasion, in which I placed the mouse, trap and all, on the plate, leaving it there for three days. The trap was an ordinary six-cent trap, and it will be noted that the metal parts of the trap are shown opaque, whereas the portion of the wood nearest to the radium is shown absolutely transparent, as if it had been exposed to X-rays. In the original photograph the mouse is also shown somewhat transparent, indicating slightly the bones. I also show you in Fig. 12 and upon the screen a slide which I have made of a radiograph of a human hand. This was exposed for eight days, and bears resemblance to an X-ray picture which has been over-exposed. In making a faint print of this, a slight trace of the bones is shown, and the embalming material employed is brought out strongly.

FIG. 12.—Radiograph of a Human Hand made by Radium in eight days' time.

This is, perhaps, the first picture made of the human hand by means of radium, and it would not have been possible, of course, to have exposed a living person to these rays for even a small percentage of this length of time. Perhaps subsequent experiments will bring out much more strongly the bone structure (the irregularity in the fingers is due to their being somewhat cramped). As X-rays will excite phosphorescence in many substances, one would naturally wonder whether there were any X-ray characteristics in phosphorescent substances.

(To be continued.)

THE SEPARATION OF THE FRICTION LOSSES IN ELECTRICAL MACHINES.*

It is usual to separate the combined bearing and air-friction losses from the brush-friction loss, but no further subdivision is carried out, as it is assumed that the air friction forms only a small percentage of the total friction. This is not generally sufficiently accurate.

In modern machines, one of the chief objects of the designer is to obtain a good cooling effect, and for this reason the air velocity and the volume of air moved are made as great as possible, and the cooling surface is increased by the insertion of gaps and passages, towards which the air is properly led by means of baffle plates, etc. Even without special cooling devices, the rotating poles of high-speed alternators and the end con-

* Translation of an article by Dr. Leo Finzi in the *Elektrotechnische Zeitschrift* for July 9.

Digitized by Google

nections of rotating armatures act as fan vanes. In this way, though the rating of the machine is considerably increased, the ventilating losses also rise considerably, and may become the major part of the total friction losses. Brush friction is easily determined by running the machines under the same conditions, first with the brushes down and then with them up, so that the term "total friction" used below will be understood to include only bearing and air friction.

One way of separating air friction from bearing friction depends on the fact that between temperatures of 15deg. C. and 80deg. C. bearing friction is inversely proportional to the bearing temperature,* whilst the air friction is, of course, independent of this temperature.

One may, therefore, state the total friction, R, in terms of an equation of the form

$$R_{(t)} = a + \frac{b}{t} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where the first term represents the air friction and the second the bearing friction, t being the bearing temperature.

It is only necessary to determine the total friction at two different temperatures in order to obtain the values of the constants a and b.

For greater accuracy the readings at the two temperatures should be repeated at various speeds.

Considering the matter graphically, it will be seen that the equation

$$R_{(t)} = a + b\,T \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$\left(\text{where } T = \frac{1}{t}\right)$ represents a straight line, whose angle ϕ (Fig. 1) has a tangent equal to b, and which cuts the ordinate axis at a (Fig. 1). Given the total friction watts at constant speed and at different temperatures, within the above-mentioned range, and plotting the total watts against the reciprocals of the temperatures, such a straight line will be obtained.

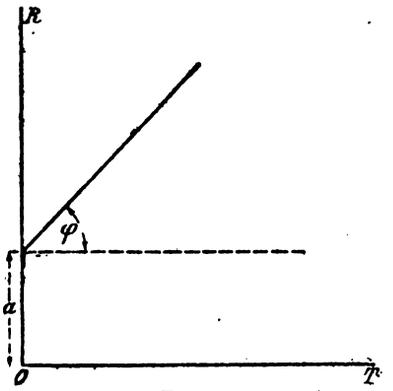

FIG. 1.

A simpler method of separating the friction losses is based on the fact that air resistance is proportional to the square of the speed, whilst the bearing friction coefficient is proportional to the square root of the speed. On this assumption the total friction watts may be expressed as

$$R_{(n)} = c\,n^3 + C\,n^{1.5} \quad . \quad . \quad . \quad . \quad . \quad (3)$$

where n is the number of revolutions of the machine and c and C are two constants, the first quantity representing the air friction and the second the bearing friction.†

If the total friction watts, R_1 and R_2, are known for two speeds, n_1 and n_2, the values of c and C may be found from the equations

$$R_1 = c\,n_1^3 + C\,n_1^{1.5} \qquad R_2 = c\,n_2^3 + C\,n_2^{1.5}$$

$$\text{for} \quad c = \frac{n_2^{1.5} R_1 - n_1^{1.5} R_2}{n_1^3\, n_2^{1.5} - n_2^3\, n_1^{1.5}} \text{ and } C = \frac{n_1^3 R_2 - n_2^3 R_1}{n_1^3\, n_2^{1.5} - n_2^3\, n_1^{1.5}}.$$

The following figures relating to a 100-h.p. three-phase motor will serve as an example of the application of the method. The rotor had a winding of which the end connections were radial and at right angles to the spindle. The speed was 600 revolutions per minute, giving a peripheral speed of 28m. per second, and a peripheral speed of the spindle in the bearings of 2·5m. per second.

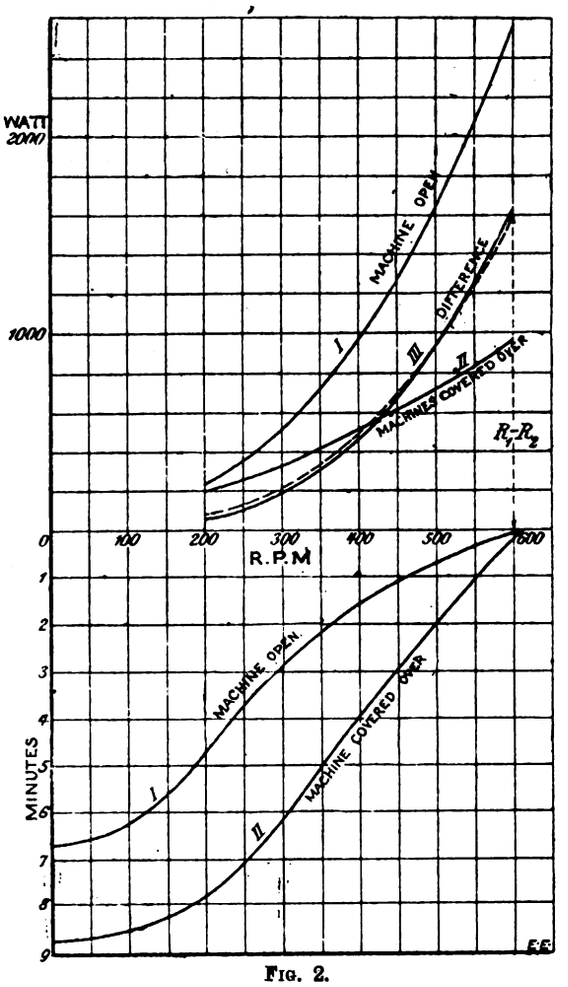

FIG. 2.

The lower curves in Fig. 2 are the run-down curves (drop of speed with time as the machine slows down from full speed) of the machine. For Curve I. the rotor was in its ordinary uncovered condition, whilst Curve II. is for the same machine with bearings in the same condition, but with a light cover arranged to rotate with the rotor, so as to reduce the air friction to a minimum.

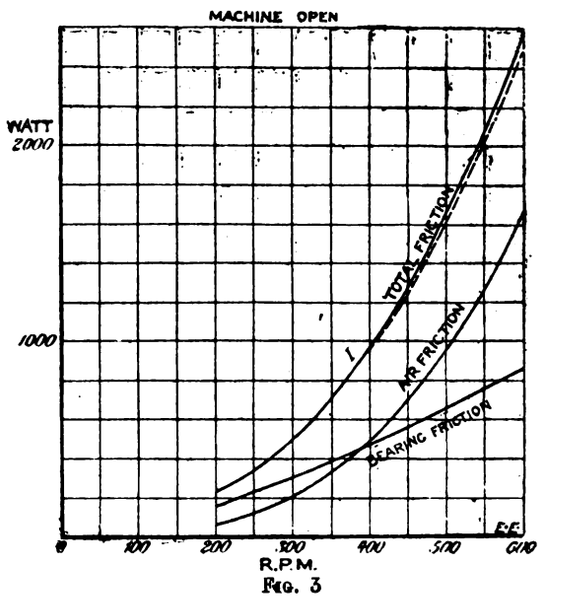

FIG. 3

The upper Curves I. and II. are the corresponding loss curves, whilst Curve III. shows the difference between the two. This represents, if not the whole, at least the greater part of the air friction. The value of the ordinate, $R_1 - R_2$, and consequently the ordinate scale, was determined by two independent direct measurements of the open-circuit loss.

* According to the investigations of Tower, Thurston, Woodburg, Deltmar, Stribeck, and Lasche.

† The proportionality of the friction coefficient to the square root of the spindle velocity holds good for peripheral speeds of spindle between 2·5 and ·8 metres per second—*i.e.*, in most ordinary cases. With ball bearings and ordinary bearings having high speeds (over 10m. per second) the friction coefficient is almost independent of the speed, and in such cases the equation $R(n) = c\,n^3 + C\,n$ should be used.

Digitized by Google

The dotted Curve III. is drawn to the equation

$$R = \frac{74}{10^7} n^3,$$

and the close agreement with the test curve confirms the assumption of the air-friction watts being proportional to the third power of the speed.

Further pairs of points were taken from that part of Curve I. within the range for which the formula, bearing friction $= C\ n^{1.5}$, holds, and the values of c and C were determined. The various values of each constant so obtained differed only by a small percentage from one another, the average values being: $c = \cdot0000077$, $C = \cdot0585$.

The total loss (dotted) and the individual losses are shown in Fig. 3. It will be seen that even at moderate speeds the bearing friction is considerably exceeded by the air friction. At 600 revolutions the latter is 1,660 watts (over 2 per cent. of the output of the machine), whilst that part of the air-friction loss which can be directly measured by covering the rotor in was 1,600 watts.

When Curve II. is used to determine the value of C, an average value of ·06 is obtained, and this close agreement with the value obtained from Curve I. is satisfactory and forms an indirect check on the accuracy of the method.

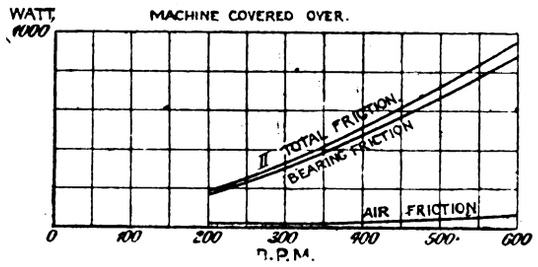

FIG. 4.

On Fig. 4 (for the covered rotor) the value of air friction, which in this case is very small, has been taken as simply the difference between total loss and bearing loss.

These methods do not possess any great theoretical value, but they are self-checking, and so may be usefully employed to obtain an idea as to the relative values of the two losses.

THE FINANCIAL IMPROVEMENT OF ELECTRICITY SUPPLY WORKS.*

BY JOSEPH A. JECKELL.

The following is a condensation of the above paper, in which, however, all the most important calculations and figures are given in full. The author commenced his paper by stating that it was written chiefly for discussion by chairmen of committees, as on them lay the policy of the commercial side of electric supply business. Electricity works were mostly designed for supplying lighting loads at a time when the technical questions were most prominent. Now the question was rather how to make those stations commercially successful, and to supply from them the demand for cheap power.

It was small manufacturers which most needed this service, as large works could put down their own plant. Also, the local authorities wished to encourage small manufacturers to do business within their areas. Power Bills were introduced to supply cheap power. As is well known, many of the Power Bills were thrown out when it was clearly proved that the local authority in the area the company proposed to supply in was actually supplying power at a rate lower than the company promised or was then doing. For instance, before the committee of which Sir James Kitson was chairman, the South Shields Corporation, when a power company proposed to come in and supply power in their area, were able to prove that they were manufacturing current at 28 per cent. less and selling it at 19 per cent. less than the company was. Again, in the case of the Leicestershire and Warwickshire Power Bill, the company proposed to come in and supply energy in Coventry. The price at which the company proposed to sell energy was 3d. per unit for the first 400 hours per quarter and 2d. afterwards. The price at which the Coventry Corporation were then selling current was 6d. for the first 91 hours in the quarter, 3d. for the second, and 1d. for all the remainder. Energy for power, heating, and cooking was being supplied at 1¾d. per unit all round—*i.e.*, a consumer using energy for eight hours a day under the company would pay 2½d. per unit; under the local authority, 1¾d. per unit; or if on the lighting tariff, 1·87d. per unit.

The author then proceeded to deal with the case of the Coventry electricity supply since it came under his charge, and he pointed out that a committee will often allow a new engineer to spend money which they refuse to the previous holder of the position. On the question of cost of energy, the author refers to the argument that for a low load factor capital should be economised by putting in an inexpensive and less efficient plant. Of course, the worse the load factor the more weight this argument would have, but the longer the plant was at work the less it would pay to save capital and use steam, because the capital could only be saved once, whilst the longer the plant was run the greater the loss due to the increased coal consumption over that of the more efficient plant becomes. It is in stations where this principle has been acted upon that the greatest difficulty will be experienced in dealing with the supply of electricity for power purposes. As an example of influence of the price of coal and efficiency of plant on the supply of power, the author gives the instance of two towns, A and B, where coal is the same price and same quality, A having an output of 1,000,000 units and B an output of 2,500,000 units, both stations working condensing.

The load factor at B is better than at A. Coal costs 1-3d. per unit more at B than at A. Had the coal costs been the same at B as at A, B station would have made £3,437 more profit, or, capitalised at 6 per cent., £57,000. *Or taking a hypothetical case*, assuming 1,000-kw. plant running 12 hours a day for 300 days in a year.

A set takes 25lb. of steam per unit.
B set takes 35lb. of steam per unit.

Say coal costs 7s. 6d. per ton and evaporates 5lb. of water per pound of coal, therefore

$$\frac{\text{Kw.} \times \text{Hours.} \times \text{Days.} \times \text{Lb.} \times \text{Shillings.}}{2{,}240 \times 20} = \frac{1{,}000 \times 12 \times 300 \times 2 \times 7{\cdot}5}{2{,}240 \times 20} = £1{,}200.$$

Therefore B plant costs £1,200 per annum more to run than A, or, capitalised at 6 per cent., £20,000—*i.e.*, this amount extra could have been paid for A plant, and still it would have cost no more than B to run. Or, where coal is dearer, take best Welsh costing 30s. a ton, and this evaporates 10lb. of water per pound of coal.

$$\frac{\text{Kw.} \times \text{Hours.} \times \text{Days.} \times \text{Price.}}{2{,}240} = \frac{1{,}000 \times 12 \times 300 \times £1{\cdot}5}{2{,}240} = £2{,}410.$$

Therefore B plant costs £2,410 per annum more to run than A, or, capitalised at 6 per cent., £40,000. This shows that however much it pays to use the most efficient plant where coal is cheap, it pays much more where coal is expensive; and it also shows what an immense saving can be made by using the most efficient plant for generating current for power purposes. As regards the type of engine to be chosen, the chief point was the economy and a range of load from half-load upwards, and the question of speed in larger sizes was not very important. It was not good policy to try to save too much in attendance and stores, and it might entail much higher maintenance charges.

Coming to the cost of supplying power, the author showed that the extra, rather than the average cost, should be considered. Thus, taking the example of a station with the following accounts: capital, £75,000; total plant capacity, 600 kw.; earning capacity, 400 kw.; sells 400,000 units per annum.

Station costs at 2d. per unit		£3,333
Capital charges at 5½ per cent.		4,125
		7,458
Revenue, 400,000 units at 4d.		6,666
Loss		£792

A demand occurs for power at 1½d. per unit, probable amount 1,000,000 units. The question is, Can this amount be supplied at this price and a profit made? One manager will say, "No, because my costs are 2d. a unit now without capital charges." Another manager works it out like this:

Extra capital required, £30,000		
Extra capital charges at 5½ per cent.		£1,650
Extra station charges		2,000
Total extra cost		3,650
Extra revenue at 1½d. on 1,000,000 units		6,250
Less cost		3,650
Profit on transaction		2,600
Less loss on lighting		792
Profit on station		£1,808

The second manager naturally closes with the offer at once and turns the loss on his station into a profit. It will be seen at once from this how very profitable it is to supply power from

* Paper read at the recent meeting of the Municipal Electrical Association at Sunderland.

an existing station. Table A is a summary of the Board of Trade returns for the years that the undertaking at Coventry has been running.

When the author took up his position at Coventry the maximum-demand system was in use, the charges being 6d. per unit for the first hour and 3d. per unit afterwards. He could not raise the first charge, as he would like to have done, but reduced the second to 1d. per unit. The system of supply was single-phase high-tension at 87 frequency. With regard to the financial position of the undertaking, the accounts for 1901 show the position of the works when it became the author's duty to try and improve the position financially. At that time the capital expenditure was £75,813. The plant capacity at the station was 550 kw., but, as is well known, it is necessary to keep one plant in reserve in case of a mishap occurring to any of the others; therefore, the earning capacity of the station was 350 kw. One can reckon on selling 1,000 units per kilowatt of earning capacity when supplying an ordinary town lighting load. Of course, if motors, tramways, etc., are supplied, where current is used for more hours a day than it is in an ordinary lighting load, more than 1,000 units per kilowatt can be sold. In that case the price obtained would probably be less than would be obtained from a lighting load, because in fixing the price due consideration is taken of the length of time that the current will be used, and therefore the number of units sold per kilowatt of earning capacity. In the station costs are reckoned all the costs of manufacture—that is, oil, stores, wages, rent, rates and taxes, etc., management, everything, in fact, except capital charges, which consist of interest and sinking fund or redemption. The station costs amounted to 3d. a unit for the year ending 1901, and the capital charges amounted to over 2·66d., making a total cost of 5¾d. The average price obtained was 4·14d.; the loss was, therefore, 1½d. on every unit sold.

In order to make the undertaking pay it was necessary to reduce the cost of manufacture or else to raise the price. The author chose the first alternative, as the capital charges were so high. It was necessary, in order to make the undertaking a financial success, to bring down the cost of manufacture under the headings of both station costs and capital charges. Had it been possible to have pulled the undertaking round by merely reducing the station costs, it would have been an extremely simple matter. It should further be pointed out that the revenue for 1901 was £5,897, and the deficit made was £2,250. It is therefore apparent that this *large* deficit was made on a *very small* revenue. Had the revenue been considerably larger, say £20,000 or £30,000, it would have been probably quite easy to have made this up by merely bringing about economies at the works, but the undertaking was suffering from an extremely limited revenue. This was chiefly due to the policy which had been pursued in the past—viz., laying mains in a very restricted area in the centre of the city. The Council had always been very averse to allowing money to be spent on mains, and as the factories are more generally on the outskirts of the town, it will be readily seen why the revenue was so restricted. After going carefully into the figures, it appeared that the only thing to do was to increase the earning capacity of the plant. This could certainly be trebled if the capital of the undertaking was doubled. It was, of course, necessary to popularise the light in order that the new plant might be fully loaded, and with this object the price was lowered as before mentioned.

The motor question had to be very energetically taken in hand. The price for heating and power and photographic printing by electric light (of which there is a considerable amount done in Coventry) was reduced to 1¾d. It was also decided to hire out motors, so that consumers might be able to try them and convince themselves of the superior advantages of electric driving over any other means of motive power. It was also decided to adopt a broad policy with regard to main-laying, so as to reach districts which had not yet been tapped. It is interesting to note that on April 1 last year £27,893 had been spent on mains, and to these were connected 27,226 lamps. During the past year £5,185 was spent on new mains, and to these mains have been connected 10,266 lamps. It ought to be mentioned that in the £27,893 there was no money included for spare ducts, and in the amount of £5,185 a considerable amount has been spent in providing spare ducts. It will therefore be noticed that though many of the old mains had been laid a large number of years, and though the new mains had only been down a few months, the cost of mains per lamp connection on the extension was considerably less than half that in the case of the old mains. This shows how very advantageous it is to extend mains widely.

Doubtless it seemed rather a drastic measure to advise a committee, when the undertaking had made so large a deficit, to double the capital and lower the price, and it would have been quite impossible to have induced the committee to take this course unless the chairman had been thoroughly convinced that it was advisable and really the only course to adopt. With the addition to the plant a change was made in the system of supply. The new machines were of the two-phase type with 50 frequency. It was found that a 600-kw. two-phase alternator could be obtained for the same price as a 400-kw. single-phase alternator. Therefore, by adopting two-phase the capital cost of the machinery was reduced, which it was extremely advisable to do in view of the already high capital cost per kilowatt. It was decided at present to keep the single-phase plant for supplying the centre of the town. The outlying sub-stations are supplied some with two-phase 50 ~ and some with single-phase only. No difficulty whatever was experienced in changing over, which was effected at the rate of one sub-station each Sunday.

The author mentioned that in the last six months they had connected up 350 h.p. of motors, and that two-phase motors are extremely satisfactory. Several of them have run quite comfortably at 60 per cent. overload for days without getting unduly warm. It is interesting to note how soon people take to motor driving when they can obtain the current cheaply, and when the Corporation is prepared to hire out motors, carrying at the same time a good stock of them so that consumers may be able to have any size they like at once, and if, as is very frequently the case, they have miscalculated the size of motor required it can be readily exchanged. By bringing about certain economies at the works the actual cost for station charges has been brought down to the same figure as for 1901. It will be seen from these figures how very little it costs to manufacture extra energy when once a station is running. In fact, it will be seen that even including the capital charges the actual cost of manufacturing current this year was the same as in the year 1901, though we sold this year 566,000 units, as compared with 341,000 units in 1901. No appreciable revenue has been obtained from the motors, except for the last quarter of 1902. The increase due to this cause will be felt very much more in the current year, or, to put the accounts in the form given in the previous hypothetical case:

Before extensions were carried out, 1901.		*After extensions have been partly carried out, 1903.*	
Capital spent, £78,513.		Capital spent, £102,712.	
Station costs	£4,358	Station costs	3,573
Capital charges	3,789	Capital charges	4,574
Total costs	8,147	Total costs	8,147
Total revenue	5,897	Total revenue	7,958
Loss	£2,250	Loss	£189

N.B.—It should be remembered in comparing these figures that, as before mentioned, the coal cost some £500 more in 1901 than it would have done in normal years owing to the greatly enhanced prices.

From the foregoing it may be considered as fairly proved (1) that the large manufacturer is desirous of obtaining a supply of electric energy; (2) that, however much the large manufacturer desires to obtain a supply of cheap energy, the small manufacturer is still more anxious to do so; (3) that it is to the advantage of the district that a cheap supply of energy is available; (4) if a power company can supply energy at a low rate, there is no reason why a local authority should not be able to supply it as cheaply; (5) that energy can be supplied from an existing lighting station at a rate low enough to induce manufacturers, and also an enhanced profit made for the undertaking.

The supplying of energy cheaply would, therefore, be an advantage to the manufacturer, to the owners of the electricity works, and to the electrical industry generally.

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s 6d. New Volume, January to July, 1903, now ready.*

THE FINANCE OF ELECTRIC SUPPLY.

The most interesting paper on "The Financial Improvement of Electricity Supply Works" by Mr. Joseph A. Jeckell, which we are reproducing elsewhere in this issue, calls attention to an all-important question. An engineer in charge of an electricity supply undertaking may be up to date in every development of the science, and may fill his station with every known device for economy and labour saving, but unless the balance-sheets of his undertaking are satisfactory financially his downfall is only a question of time. We have in mind a case in point in connection with an undertaking not a hundred miles from our office. In this instance the engineer had no less than three different systems of supply, each with particular advantages for different loads which occurred within the area. He had converting links between these systems, he had a large battery of accumulators with automatic regulating gear to keep the voltage of supply absolutely constant (which was never used), he had every labour-saving appliance and convenience which his staff could devise and money could buy, but he had not a paying load. In consequence, his capital charges were enormous, and his directors were firmly impressed with the idea that an all-day power load at 2½d. per unit would not pay. We need hardly add that in due time the engineer's services were dispensed with in favour of a gentleman who had grasped the simple idea that the real object of an electricity supply station was to supply electricity. The same moral underlies the paper referred to above. Mr. Jeckell found at Coventry an undertaking heavily capitalised and yet quite incapable of meeting the commercial requirements of the town. He recognised that any economies introduced would be absolutely unavailing unless a much larger load could be attracted. The mains already laid did not extend through more than a small proportion of the town, so that the extension of these was an absolute necessity if any large number of new consumers were to be connected. The laying of these mains and the remodelling of the station was an engineering matter with which no especial difficulties had to be faced, but they were, of course, made with a view of giving the utmost economy and the largest possible output for a given capital expenditure. The most difficult point Mr. Jeckell had to face was that of finance and of persuading not only his committee, but through that committee the Corporation of Coventry, that the old story of the orange woman was true after all. It will be remembered that this interesting and historic old lady explained to a passer-by that while she sold her oranges at two for 1½d. they actually cost her when delivered into her basket 1d. each, and that it was the quantity she sold which paid. Thus, when the average cost per unit supplied from the Coventry station amounted to 5¾d., which was 1½d. above the average price obtained in 1901, Mr. Jeckell had the onerous task of persuading his Corporation to largely increase the capital expenditure and also to decrease the price charged per unit. Up to the present there has hardly been time to gauge the full effects of the alteration, but the move in the right direction is so decided as to completely warrant the steps which have been taken. Thus, in 1900, when the average price obtained per unit was 4·14d., the average loss was 1·57d. per unit, and the rates were called upon to make good a deficiency of £2,250. In the next year, 1901, the average price obtained fell to 3·83d., and the rates were called upon to the extent only of £1,808. Last year, when Mr. Jeckell's alterations really began to have an effect on the balance-sheet, the average price obtained per unit had gone down to 3·37d., and the deficit was quite a nominal one, being

Digitized by Google

under £200. In the two years the consumption of electricity had gone up from 341,810 units to 566,731. These improvements were made in spite of reorganisation troubles and the fact that capital expenditure always becomes a burden on the undertaking before it is remunerative. The above results are due to a large extent to the engineering improvements in the plant, but these are quite subservient to the commercial reorganisation which has taken place. The undertaking is now supplying motor loads at 1¾d. per unit, or at under a third of the price which it cost the Corporation to produce the unit at in 1901. The above results justify the conclusion that the good engineer who has sound commercial ideas, and can make others act on them, is the one to succeed in any supply undertaking.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

WIRELESS TELEGRAPH ALARM.

SIR,—I have noticed the publication of my letter on the above subject and your notes on the same in your issue of the 21st inst., for which I thank you. I note with pleasure that you have not objected to what I have said in my letter. I respect your opinion as I respect those of everyone, but it is remarkable that I, in order to defend my proposition, have given proofs and arguments, while you state yours without opinions or without combating my reasoning. You say that "the proof of the pudding is in the eating," but I have eaten the pudding, and have found it very good. From my experiments with apparatus I am assured that the wireless fire-alarm is the only solution possible and practicable to give directly automatic warning to fire stations. On the other hand, from regulating in the right way the receiving apparatus, I am convinced that it will not respond to signals of the ordinary wireless telegraphy—that is to say, transmitted at ordinary speeds—while it will respond to elongated signals given by the fire-alarms. By this means, then, I avoid interference with the stations of wireless telegraphy in towns. I gather that you doubt the success of wireless telegraphy on land. I hope that further trials and practical applications of my system will remove your doubts, and that then you will give me your support in the same way that you now dispute the possibilities of my system.—Yours, etc., E. GUARINI.

[We are afraid that if we had to give proofs for all the beliefs that are within us in connection with wireless telegraphy, we should allow our notes on correspondence to occupy the major part of our columns. We think that further comments or correspondence on the wireless fire-alarm system of Mr. Guarini should be deferred until the trial of the system on a practical scale.—ED. *E. E.*]

WIRELESS FIRE-ALARM.

SIR,—I shall be glad if you will allow me space to deal with one or two statements in Mr. Guarini's letter in your issue of 14th inst. I do not require to travel over the whole of the ground he covers, because your footnote points out one objection which must occur to every practical man. There are, however, others, and they are of a kind not easily overcome. I take it that Mr. Guarini is aware that the monopoly of the right to transmit telegraphic signals, automatic or otherwise, is vested in Great Britain in H.M. Postmaster-General, and that before his system can come into use it will require to be examined by the technical experts of the General Post Office, and a special license granted to practice. As a matter of opinion, I take it that no automatic system of wireless telegraphy will be licensed until such time as the authorities have convinced themselves that the transmission of any wireless signal will not interfere with, or be interfered with, by any other class of wireless message, commercial or otherwise. This difficulty, of course, does not arise in the case of brigade connections by metallic pairs such as the modern fire-alarm engineer confines himself to.

Another point to be considered, too, is that on account of service arrangements the connection between automatic systems and the brigade station seldom exceeds a mile and a-half, and averages about three-quarters of a mile, and that in consequence the cost is scarcely of much importance. One of the first duties of the practising fire-alarm engineer is to ascertain that the brigade with which he proposes to connect is well found and able to turn out with adequate appliances within a reasonable time, and to cover the ground at a fair rate of speed. Without mentioning names, a case which came within my own experience illustrates this point. I was sent for to design an installation for the protection of a large cotton mill, which was situated about 1¾ miles from the brigade station. The building itself presented no difficulty, but the road to be travelled was not an easy one, nor one on which a good pace could be made. After taking particulars, my next call was at the fire station, and there I found that the average time for getting into the street was little short of 30 minutes. The horses did not belong to the department, but were retained at an annual charge from a contractor who had the right to use them for sanitary and general haulage. Upon receipt of an alarm, the horses required to be called in from wherever they happened to be, and thus the time was lost. Looking at the matter fairly, in the first place, there would be a loss of 30 minutes, plus another 20, to cover the distance to the mill. I felt obliged to advise my clients that there was nothing in an automatic alarm system which would give them, under the circumstances named, the protection they sought. This is, I admit, a remote instance, but on the whole a conscientious engineer will not couple up indiscriminately, and prefers to protect buildings which are not too remote from a well-found brigade. I find, as a matter of experience, that the average cost to our clients of separate aerial pairs, or of metallic circuits forming the component parts of aerial or underground cables, does not exceed £3 a year, and this covers upkeep and occasional testing. I do not see, therefore, that, glad as I shall be to welcome wireless telegraphy when its reliability has been proved, there is anything commercially important in its adoption for automatic fire-alarm purposes.

Another objection—and this one is more difficult than any other to overcome—is the repugnance of the average brigade officer to rely upon telegraphic signals purely and simply. In our practice we find that primary reliance is placed upon the lowering of a legibly engraved shutter, and the coded message is treated as confirmatory only. Every fire chief fears that in the rush of a turn-out his dutyman will interpret a dash for a dot or *vice versâ*, and that the detachments will be sent scurrying away in a direction opposite from that in which they are needed. Even in the finest stations in the kingdom—and we have installations connected with many of them—the shutter is absolutely demanded, and our practice would be very much restricted by brigade authorities if we asked them to take a coded message apart from the shutter referred to. Few brigades have competent electricians on their staff who are capable of looking after the receiving set, and where these exist they make no secret of their appreciation of the shutter. Watch-room duty is continuous in the fire service, but the electrician cannot always be on deck. The responsibility for deciphering a code signal falls, perhaps, upon a junior officer or a senior fireman, and he, particularly toward the end of the week before the watch changes, tires in the small hours, and is not at all unlikely to err—especially in messages which consist entirely of combinations of one character, whether of dots or of dashes. It is not entirely his fault. As manufacturers, be as careful as you will, the slightest loss of speed in any transmitter forming one of a number coupled up to the same fire-station receiver has the tendency to lengthen the dot, until it is difficult to draw the line between the dot of the slow and the dash of the normally speeded instrument. Speed fluctuation in transmitters sending mixed dot-and-dash combinations cause no trouble, because the length of each character is relatively affected. These difficulties only reveal themselves in the course of an extended practice

Digitized by Google

when one has a considerable number of installations coupled up with the central fire station, and under the constant supervision of interested and watchful critics. Can Mr. Guarini so attune his transmitters that each, whilst printing upon a common receiver at a uniform rate of speed, can pick out and drop its own particular shutter in a case, say, of a hundred? The brigades do not like the shutter by itself, because a line contact of any description will bring it down, but they are willing to accept, and they encourage the use of, the combination. If it is possible—and this is proven—to interpolate "rats" in a wireless message, what guarantee is there that the presence of an extra dash or dot from some other system, or a jumble of complete messages, may not confuse the brigade, and subject them to the chagrin of knowing that there is a fire in progress without being able to ascertain where. I am not writing as a scientist, but as an engineer, with a growing knowledge of the difficulties which exist.—Yours, etc.,

Glasgow, Aug. 20, 1903. GEO. H. OATWAY.

P.S.—Since writing the above I have seen Mr. Guarini's letter in yours of the 21st, and need only say, as the author of the specification he refers to as "the conditions printed by the Fire Prevention Congress of London," that he not only does not "furnish the best and perhaps the only solution," but that he fails to comply with the primary essential, "to detect the fire at a uniformly early period under all atmospheric or industrial conditions." This he can never do with the detector he employs, and there will be time enough to consider his compliance with the other condition when he has secured the license and overcome the other practical difficulties enumerated above, and when he can refer his critics to industrial installations under brigade supervision instead of diagrams or elementary demonstrations.—G. H. O.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

613. I have two motors, 2¼ h.p., 85 volts, and my voltage on the mains is 110. Please tell me the best economical method of using above motors.—J. W.

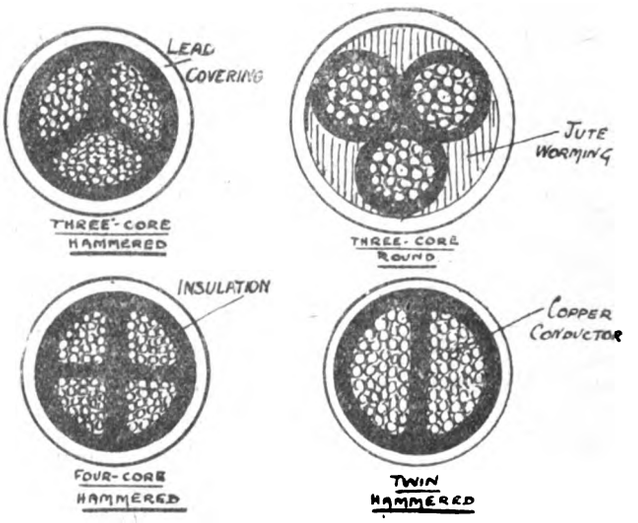
614. In motor starters, graded in G.P. and having wires with a rating proportional to dia.$^{\frac{3}{2}}$, how should the constant K (or the diameter of the wire) vary from the first to the last contact for the same temperature of wire, and for the greatest economy in resistance material, allowing the same space of time on each contact (say three seconds). Consider a 5-h.p. starter with 16 contacts, and a similar one with 24 contacts.—J. A.

ANSWERS.

Question No. 605.—What are the advantages and disadvantages of hammering electrical cables out of the ordinary round shape?

Best Answer to No. 605 (*awarded* 10*s.*). — Taking the question quite literally, there appears to be *no* advantage in hammering electrical cables out of shape, either to the cable or the hammerer. The scrap heap might increase its load. The exact amount of disadvantage attending the process depends on circumstances. For instance, if the cable happened to be a street main carrying a heavy load at, say, 8 p.m. on a winter's Saturday evening, probably a large portion of the town would be thrown into darkness, the engineer would be forced into the use of very strong and searching words, and the hammerer thrown into the nearest jail for a month's sojurn without the option of a fine, and serve him jolly well right. I presume, however, that the question is intended to read, "What are the disadvantages and advantages of hammering *the conductors* of electrical cables out of the ordinary round shape?"

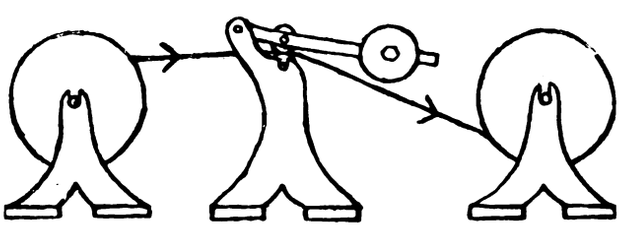
It is sometimes usual to hammer or roll the usual circular stranded conductors of twin, three-core, or four-core cables into segmental shape before insulating. As can be seen by comparing cables made up of hammered conductors with those of ordinary round strand (see drawing), the chief



advantage is that a smaller and mechanically better cable can be made, no space being wasted, the insulated conductors lying compactly and geometrically together. No jute worming is necessary to fill up the spaces which are left when round conductors are stranded together. Then the cable with hammered conductors is also cheaper by reason of its compactness and smaller diameter, less lead being used to cover it.

It is much cheaper and easier to joint or tap off services from a three-core cable than from a triple-concentric, and this is a consideration in a distributing system. In jointing the conductors the jointer can easily hammer the strand sufficiently circular again to make a good joint in a sleeve or fitting, so that the shape is no real disadvantage in making joints. I know of no practical disadvantages with this type of cable as compared with round conductor cable. DUPLICATOR.

Answer to No. 605 (*awarded* 5*s.*).—Although stranded conductors are often formed into sections other than circular, it would be very unusual and unsatisfactory to alter the shape by hammering. Suppose a stranded conductor is required to have an elliptical section; after having been laid up as a circular strand, the desired shape might be obtained by some such method as depicted in sketch. The strand is drawn over a grooved roller having



a weighted jockey roller above By altering position of the weight the pressure is adjusted to suit the work in hand. Of course, by increasing the pressure and drawing through several times, the strand may be made to approximate in shape to a ribbon. Some makers force the strand into rectangular and other sections by means of hydraulic pressure. There are several advantages due to this alteration in section, among the principal being the utilisation to greater advantage of the winding space on the armature cores of dynamos, reduction in size of electrical conductors, as seen in the well-known "clover-leaf" pattern, by flattening out the strand employed for lightning conductors greater flexibility is secured in manipulation, also for ornamental braids, etc.

Digitized by Google

Two other advantages also might be instanced, but they are scarcely worth mentioning—viz., that by increasing the periphery with a given sectional area greater radiating power for heat is obtained, and in the case of alternating current the loss due to skin effect would be less. Disadvantages are that unless the rolling or pressing is carefully done the conductor may be hardened, and so have its electrical resistance increased, and there is more difficulty in covering, with cotton or other material, a conductor having a ribbon or an elliptical than one having a circular section.—M. M.

Question No. 606.—It is required to obtain current at 200 volts from two shunt-wound dynamos, each giving 100 volts, and it is found that if the two machines be simply connected in series, with the shunt of each machine across its own brushes, the field of one dynamo dies away and is then reversed in direction, whilst if the field windings are connected in series and not connected at the intermediate point between the two armatures, the machines run all right. Explain this.

Answer to No. 606 (*awarded* 7*s.* 6*d.*).—The effect noticed with the first arrangement is due to an ordinary loss of field, aggravated by the fact that with two machines in series a drop in the voltage of one machine of a given percentage only corresponds to a drop of half that percentage in the current through the two armatures, assuming that the volts of the second machine keep constant. Suppose that the two machines are running at 100 volts each, with a certain amount of current passing, and that then a slight drop in speed (and in volts) occurs on one dynamo. If this dynamo were working alone on the circuit, this drop in volts would produce a corresponding drop in armature current of equal percentage, and this would immediately lead to a rise in volts again, but as two dynamos are in series, the armature current will fall only half this amount, so that this self-righting tendency will be much reduced. Now, the stability of any shunt dynamo, especially of one working with only slightly saturated magnet iron, depends largely on this self-righting tendency, due to a reduction in the armature reaction following any drop in voltage, however set up. Naturally, therefore, the instability of a given machine is increased when used in series with a second machine.

Once the loss of field commences there is nothing to stop it, and the volts of the unstable machine will continue to fall. When they have fallen to zero, the current through the armature will have half its original value (assuming that the voltage of the second machine keeps constant, and that the external resistance is also constant). This amount of armature current will be sufficient to set up a small magnetic field in the reverse direction, and this will enable the shunt to start building up a field in the reverse direction, as described in the question. The volts of this dynamo will now be opposing those of the other machine, producing a still further reduction in external current, and these opposing volts will increase until they equal the volts of the other machine, and the external current falls to zero.

If, now, instead of connecting each shunt across the brushes of its own machine the two shunts are simply connected in series across the mains, a drop in voltage of a given percentage on either machine only affects the shunt current of each machine by an amount equal to half this percentage, and at the same time the total external current also falls by a percentage equal to half that of the voltage change in the one machine. In this way the relative changes of shunt current and armature current are as favourable as regards stability as in the case of a single shunt machine running alone, and much more favourable than when two machines are in series with each shunt connected to its own brushes.—Q

Answer to No. 606 (*awarded* 7*s.* 6*d.*).—It does not state in the question whether these two shunt machines each give the same output or run at the same speed. If one of them is a smaller machine than the other, the conductors in the armature of the smaller machine will tend to heat up under load and cause a larger volt drop in the armature, thus diminishing the voltage at the terminals of this machine. The shunt of the smaller machine would receive less current, and thus the field would be diminished. Through the field being weaker the armature conductors would not cut so many lines of force, and thus the voltage would be still more lowered at the terminals. The shunt current would be still further reduced, and this diminishing action would go on until it would die away altogether.

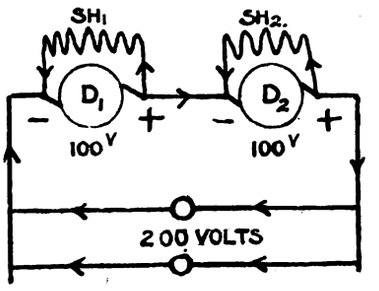


FIG. 1.

In Fig. 1 the dynamos, D_1 and D_2, are shown connected in series with their shunts, Sh_1 and Sh_2, connected across their respective terminals. The path taken by the current is indicated. Now, it has been shown previously that if D_2 is a smaller machine than D_1 the voltage of D_2 may die away. Let us suppose it has died away; what happens? The dynamo D_2 is simply conveying the current generated by D_1 through its armature, and as its shunt forms an

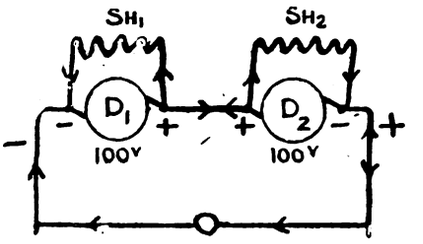

FIG. 2.

alternative path for the current, a portion of the current flows through it *in the opposite direction* to that when D_2 was itself supplying its own shunt current.

In Fig. 2 the new state of things is shown. The shunt current in Sh_2 now being reversed, D_2 will start generating in the opposite direction, and oppose the current generated by D_1. As D_2 is now generating it will be able to supply its own shunt current or part of it, and the two machines

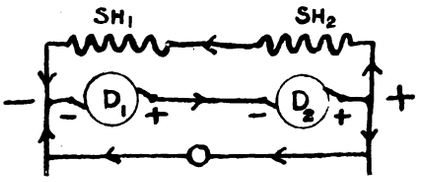

FIG. 3.

are working one against the other. Even if the machines are exactly similar, the above result may happen if the speeds and resistances of shunts are not so adjusted as to make the E.M.F.'s of the machines rise and fall in the same ratio. If the shunt of one of the machines—say D_2—heats up more than the other, then the same cycle of events will be gone through as previously described.

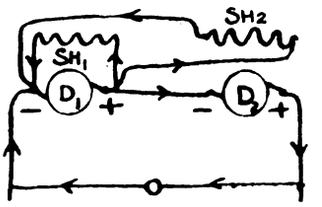

FIG 4.

The writer has had a great deal of trouble running two shunt machines in parallel through the E M.F.'s of the machines not rising and falling in the same ratio. So many things may cause reversal if the machines are connected as shown in Fig. 1, that it is preferable to connect the two shunts in series as shown in Fig. 3. In this case the

Digitized by Google

current through the shunts, Sh_1 and Sh_2, will always be flowing in the same direction. There is, however, this disadvantage about this arrangement, that it is most likely that the machines will take a long time to generate current. In all probability one machine will start generating first, but as the two shunts are in series they will offer a high resistance, and as this first machine can only generate 100 volts, only a small current will flow through the shunt circuit. It might be advisable to ascertain which machine builds up its voltage the quickest, and connect the shunts of both the machines in parallel to the terminals of this machine. There would be no reversal, and the machines would quickly start generating.—W. A. T.

Answer to No. 606 (*awarded* 5*s.*).—No mention is made in the question as to whether the dynamos are exactly similar. Let us first suppose, for the sake of convenience, that one machine (No. 2) is intended for a greater output than the other. As the current through the armatures increases so will the demagnetising effect increase, and this will be of relatively much greater importance in the case of the machine having the smaller output. Suppose the machines connected up as in Fig. 1. Then, owing to the

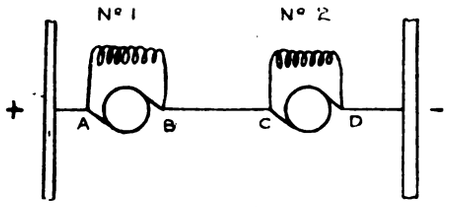

Fig. 1

field of No. 1 being weakened by the demagnetising effect of the armature current, the potential difference between A and B will fall. This will cause a diminution in the shunt current of No. 1, thus further weakening the field. The total E.M.F. of the two machines, and consequently the current, will fall, and this will reduce the demagnetising effect slightly, but it is obvious that as machine No. 2 is, comparatively speaking, unaffected, the percentage fall of potential difference between A and B will be much greater than that between A and D. Hence the demagnetising effect of the current in armature No. 1 will be greater with respect to the field of No. 1 than it was at first.

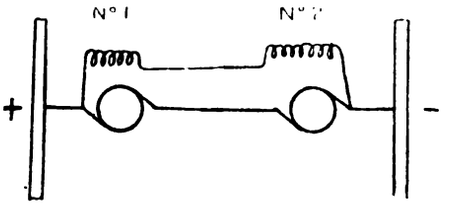

Fig. 2.

The above process will be continuous, and the field of No. 1 will eventually disappear, and since current will still be urged through the armature of No. 1 by machine No. 2, the field will finally be reversed. The same explanation will suffice if the two machines are apparently similar, because some trifling difference in the construction will cause the demagnetising effect of the armature current in one machine to be slightly greater than in the other, and the former machine will eventually have its field reversed. If the machines are connected up as in Fig. 2, when the armature reaction weakens the field, the main current and shunt current will drop proportionately, and thus the field due to the shunt of No. 1 will not be overpowered.—W. H. N. J.

Answer to No. 606 (*awarded* 5*s.*).—When two shunt machines are run in series, the shunt of each machine being connected across its own brushes, as shown in Fig. 1, they have a tendency to reverse one another. This is owing to the fact that when the current is reduced in the shunt of one machine its voltage drops. This drop in volts causes a further reduction in the shunt, the field gradually dies away, and finally a complete reversal of polarity takes place. If the shunts are also connected in series, as shown in Fig. 2, reversal of polarity in either of the machines cannot take place, as the same current flows through both shunt windings. The successful series working of two shunt machines may be ensured by cross-connecting the fields, as shown in Fig. 3. It will be seen that the field of machine A receives current from B's armature, the current from A's armature exciting B's field. Should

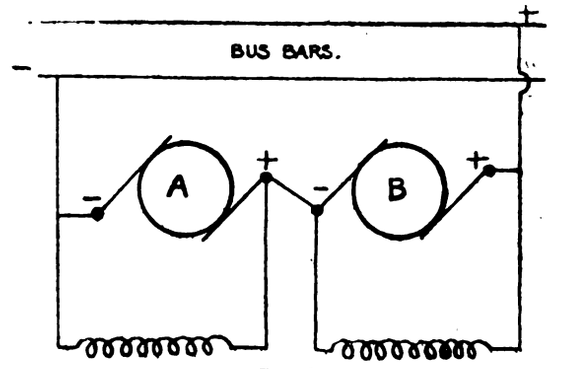

Fig. 1.

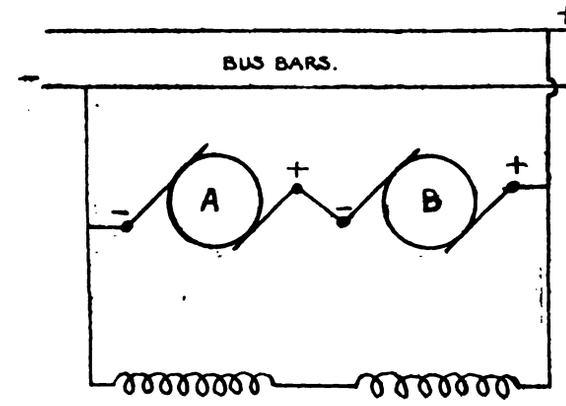

Fig. 2.

the current in the shunt of machine A be reduced, the voltage of machine B, which has caused this reduction, will also be reduced. It will, therefore, be seen that it is

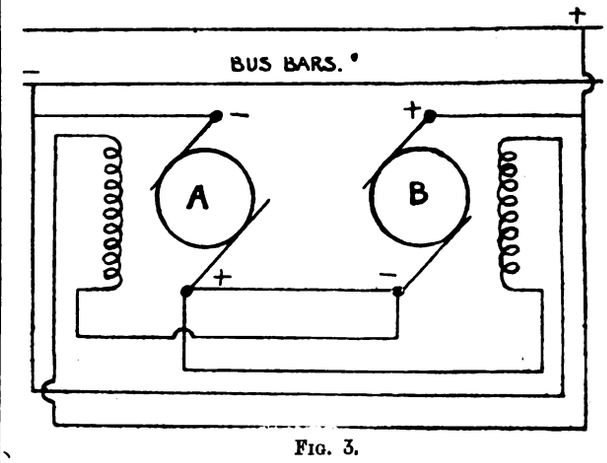

Fig. 3.

impossible for either machine to have the polarity of its shunt reversed, as any increase or decrease in the exciting current must affect the fields of both machines.—J. W. R.

FORTHCOMING EVENTS.

Iron and Steel Institute.—Summer meeting, Barrow-in-Furness, September 1-4.

Municipal and County Engineers.—Meeting at Hastings on September 11 and 12.

British Association.—Seventy-third annual meeting, September 9, Southport.

THE BRITISH ASSOCIATION.

The following is the provisional list of papers to be read before Section A (physics and mathematics) of the British Association at the forthcoming Southport meeting: "On the Treatment of the Thermo-Dynamics of Irreversible Processes," by Mr. J. Swinburne; "Granular Structure in Solids," by Mr. G. Beilby; "Explosive Pressure and Rate of Combustion of Cordite," by Mr. J. E. Petavel; "Simultaneous Solar and Terrestrial Phenomena," by Sir N. Lockyer; discussion on "The Nature of the Emanations from Radioactive Substances," opened by Prof. Rutherford—Profs. J. J. Thomson, Dewar, Soddy, and Armstrong will take part; "Report of Electrical Standards Committee," by Dr. R. T. Glazebrook; "On the Use of Vectorial Methods," by Prof. Henrici, with discussion; "On the Use of Condensers as Multipliers to Extend the Range of a Multicellular Voltmeter," by Prof. Marchant; "On Design and Working of Ballistic Galvanometers," by Mr. P. H. Powell. Meteorology will be strongly represented, owing to the meeting of the International Meteorological Committee taking place at Southport at same time.

Following are the provisional arrangements for Section F (economic science and statistics): Thursday, Sept. 10—presidential address of Mr. E. W. Brabrook, chief registrar of Friendly Societies; Friday, Sept. 11—discussion on "The Wealth of the Country and what should be done with it," opened by Sir Robert Giffen. Monday, Sept. 14—papers and discussion on the economic aspects of the fiscal controversy, as follows: "Modern Economics and Free Trade," by Dr. E. Cannan; "Failures to Attain the Ideals of Free Traders," by Prof. W. Cunningham; "Statistical Methods and the Fiscal Controversy," by Mr. A. L. Bowley; "Comparative Statistics of our Trade with our Colonies, U.S.A., and the Protected Countries of Europe," by Mr. B. Etlinger; and probably papers on "History of Retaliation," "History of Commercial Relations with Canada," and "Statistics on Production." Thursday—final report of committee on "The Economic Effect of Legislation Regulating Women's Labour"; "Physical Deterioration and the Poverty Line," by Mrs. Bosanquet. The following other papers will probably also be read before this section: "Depreciation and Sinking Funds in Municipal Undertakings," by Mr. S. H. Turner; "The Growth of Rates," by Dr. Ginsburg; also a paper on "Garden Cities."

The preliminary programme of papers in Section G (engineering) is as follows: "The Problem of Modern Street Traffic," and "An Account of the Manchester Municipal School of Technology," by Lieut.-Colonel Crompton, R.E., C.B.; "Protective Devices for High-Tension Circuits," by Mr. W. B. Woodhouse; "Permanent Set in Cast Iron, due to Small Stresses, and its Bearing on the Design of Piston Rings Springs," by Mr. C. H. Wingfield; "Refuse Destructors and Power Production," by Mr. W. F. Goodrich; "The Rebuilding of Kew Bridge," by Mr. C. A. Brereton; "Parallel Running of Alternators," by Mr. B. Hopkinson; "Balancing of Large Engines," by Prof. J. Perry; "Pendulum Apparatus for Testing Steel as Regards Brittleness," by Captain H. Riall Sankey, R.A.; "A New Form of Mirror Extensometer," by Mr. J. Morrow; "Clutches," by Prof. H. S. Hele Shaw; "Ventilation of Tube Railways," by Mr. J. W. Thomas; "Liquid Fuel,' by Mr. A. M. Bell; "The Potable Waters of S.W. Lancashire," by Mr. J. Campbell Brown; "A History of the Discovery of Natural Gas in Sussex," by Mr. R. Pearson; "The Manchester and Liverpool Express Railway," by Mr. F. B. Behr; "Aluminium as an Electrical Conductor," by Mr. J. B. C. Kershaw; "The Water Supply of South-West Lancashire," by Mr. J. Parry; "The Tidal Régime in the Mersey" and "Electric Traction," by Mr. J. N. Shoolbred; "A Further Note on Gas-Engine Explosions," by Mr. H. E. Wimperis; "The Single-Phase Repulsion Motor," by Mr. W. Cramp; "Steam Traffic on Common Roads," by Mr. T. Clarkson; "The Rate of Fall of Rain at Seathwaite," by Mr. H. R. Mill; "Smoke Abatement," by Mr. W. G. Popplewell; "Illustrations of Graphical Analysis," by Mr. J. Harrison; also reports of the Small Screw Gauge Committee and the Road Traction Committee. In connection with Section G, visits have been arranged to the following, among other, places of engineering interest: the Manchester Municipal School of Technology; the works of the British Westinghouse Electric and Manufacturing Company, Trafford Park; ss. "Lucania," Liverpool; the British Insulated Wire Company's works, Prescot; the L. and Y. Railway Company's works, Horwich; the Wigan Deep Coal Pit.

In Section L, devoted to educational science, it is proposed to devote two days (Sept. 10 and 11) to a discussion on "School Curricula," based on a series of short papers. Introductory papers have been promised by Miss Burstall and Messrs. M. E. Sadler, J. L. Paton, W. L. Fletcher (Liverpool Institute), John Adams, T. E. Page, and others. A joint meeting with the Geographical Section will be held to discuss the "Teaching of Geography." In addition to the above subjects there will also be discussions on the reports of committees on the conditions of health essential to the carrying on of the work of instruction in schools; the teaching of natural science in elementary schools; the influence exercised by universities, and examining bodies, on secondary school curricula, and also of the schools on university requirements; the teaching of botany in schools.

THE SHIFT ENGINEER.

There was a curious foreigner,
Who always wished to know
The meaning true of every term
And why we called it so.
He came across a term one day
That puzzled him no end,
And "Vat is Ingénieur-du-Shift?"
He asked of every friend.

The first he asked, a councillor
Whose town had got the juice,
Was not so very certain, but
He made up in abuse.
"They come and work a fortnight, when,
"To get a wages lift,
"They leave us for another job.
"They're always on the shift!"

The next he asked a Boniface,
At whose hotel he stopped,
Was noted for his bottled beer
And knew the men who mopped.
He gave it his opinion that:
"The term Shift Engineer
"Applies to those Electric chaps
"Who come and shift my beer."

But when he asked a lady friend
She blushed a crimson hue
And tried to change the subject, but
That did not suit m'sieu.
At last she bravely blurted out:
"The finest one on earth
"Is a gentleman in Paris, and
"His name is Mr. Worth."

B. C. H. J.

APPOINTMENTS VACANT.

Assistant Electrical Engineer, Londonderry, £130 per annum. See advertisement in last issue.

Mains Superintendent, Bury, £120, rising to £150 per annum. See advertisement in previous issue.

Pupil or Junior Draughtsman. See advertisement in former issue.

Assistant in the Distribution Department, Croydon. Salary to commence 20s. to 25s. per week, according to qualifications. See advertisement.

Switchboard Attendant. Salary, 10s. per week. See advertisement.

Electrical Engineer for mine work abroad. See advertisement.

Manager with knowledge of the trade in electrical accessories. See advertisement.

HAMMERSMITH ELECTRICITY UNDERTAKING.

The report of the borough electrical engineer upon the annual accounts for the year ended March 31 last states that the amount of the loans has increased by £24,845, but of this amount the committee still have £5,981 in hand as cash, and a stock of over £4,000 of goods held in readiness to execute work chargeable to capital account, from which they have not reaped any benefit for the year under review. The sinking fund for the year is slightly heavier on account of one of the loans having to be repaid in 10 years, instead of 42 years. Another loan has been taken up amounting to £8,800, on the same terms, making a total of £10,700 borrowed for this short period. This money is required for meters, service lines, etc. In comparing this year's surplus with previous years, it must not be forgotten that all the recent loans bear interest at the rate of 3½ per cent., whereas at the commencement the committee paid only 2¾ per cent. to 3 per cent. It is interesting to note that the surplus would have been about £850 greater if all the capital had been obtained at an average of 3 per cent. This shows that the committee should restrict their borrowings, if possible, until money is cheaper. The revenue account shows a substantial increase, but, unfortunately, the receipts are not so great as estimated. The engineer goes through the accounts *seriatim*, and shows that the gross profit is £10,930. 2s. 7d., which leaves a net profit or surplus of £1,063, as set out in the net revenue account. The total surplus since the commencement now amounts to £3,814 after paying all sinking fund charges, but without any further allowance for the depreciation of the assets After six years' working the sinking fund represents only 7·4 per cent. of the total capital borrowed, and he does not consider this sufficient provision for the physical deterioration of the plant, and will not maintain the assets at their reduced book value, even if the only object is to make the plant last during the period for which the loans have been obtained, and then obtain new machinery by again borrowing. This will not achieve the gradual purchase of the undertaking, which will thus always be saddled with heavy loans In order to provide for the full depreciation (and the value of this physical deterioration of the plant has disappeared just as surely as the coal which has been consumed), it will be necessary every year to set aside out of current revenue a definite percentage of the capital borrowed, so as to maintain the assets at their full book value. This fund should be liberally drawn upon for new machinery each year, and should not be allowed to accumulate. During the past year there has not been any depreciation or renewal fund, so that all items which could not properly be placed to capital account have been charged direct to current revenue as "betterment," but as sufficient provision has not been made in previous years for depreciation, the whole of our accumulated surplus should be placed to the credit of a depreciation fund. The "betterment" charges can then be debited to this account, and removed from the revenue account, a sum being written off from the profits to allow for this year's depreciation. The question then arises whether the money so set apart may properly be employed in the business itself, or whether it should be invested outside the business. If the object of this fund is to provide ready money for some sudden call, the latter plan may be expedient, but in a manufacturing business the reserve funds may generally be best employed in it, and such a use of the reserve will go to diminish the need for borrowing. The committee have to pay 3½ per cent. on their borrowed money, whilst the return on the capital employed is nearly 6 per cent., and as any safe investment outside the business will only return about 3 per cent., there is every inducement to employ their reserves, set aside, either for depreciation or otherwise,

Digitized by Google

in the development of their own business. A return of the progress made by the department in comparison with last year is appended, which shows that the committee will very soon have to consider the question of extending the plant.

Below we give an abstract of the accounts for the year. The total expenditure on capital account has been £196,311.

REVENUE ACCOUNT.

GLASGOW ELECTRICITY UNDERTAKING.

We have received a copy of the report of the Electricity Committee to the Corporation of Glasgow, together with the accounts for the year ended May 31 last. It shows that the gross revenue for the year amounts to £127,004. 6s. 6d., and the working expenditure to £51,138. 19s. 7d., leaving a balance of £75,865. 6s. 11d., out of which the committee had to meet the following statutory requirements: (1) interest on loans, £33,275. 8s. 2d.; (2) sinking fund, £11,770. 15s. 7d.—total, £45,046. 3s. 9d., leaving a balance on the year's ordinary working of £30,819. 3s. 2d., from which deduct proportion of cost of lamps and fittings supplied to consumers consequent on change of voltage, charged to this year's revenue account (£6.536. 7s. 1d.), and the legal and parliamentary costs of the Glasgow (Kinning Park) Electric Lighting Order, 1902 (£992. 11s. 8d.), leaving a net balance of revenue over expenditure of £23,290. 4s. 5d. The committee, on consideration, have come to the conclusion that, in addition to the reduction of debt by sinking fund and writing off the loss on realisation of plant which is being dispensed with in consequence of change of voltage rendering the plant unsuitable for the purposes of the Corporation, amounting in Waterloo-street station to £6,455. 7s. 2d., and in Kelvinside station to £1,370. 13s. (total, £7,826. 0s. 2d.), there should be written off the several items comprising the capital account in name of depreciation for the year now closed, a sum of £29,359. 10s. 4d. The total amount thus proposed to be written off for depreciation and loss on realisation of plant, against revenue account, is £37,185. 10s. 6d., making a debit balance on the year's operations of £13,895. 6s. 1d., which in terms of the Glasgow Corporation Electric Lighting Order, 1890, is, in the meantime, transferred to the debit of the gas account. The committee note with pleasure the increasing revenue of the department. There is, as compared with the previous year, an increase in the sums received from all sources of £23,000, without any corresponding increase in the working expenditure. The cost of generation and distribution is less, particularly in the item of fuel, this being due not only to a fall in the price of coal, but also to a still further economy on the moderate working of the previous year. The increase in revenue, combined with the economy in working costs, has resulted in leaving a balance on the year's ordinary working of £30,819. 3s. 2d., as compared with £14,514. 6s. 3d. last year. This increased surplus on the year's ordinary working has, however, been neutralised to some extent by the increased amount paid for changing consumers' installations to the higher pressure which is now almost completed throughout the city. This increase has been caused by the special effort which has been made to bring this work to a close as soon as possible. It is probable that next year this item of charge will be small, and that by the year after next it will have entirely disappeared as an item of account. In addition to these extra expenses there have been, as before stated, special sums written off revenue account in connection with the forced realisation of the Waterloo-street plant With these facts before them the committee look confidently forward to a prosperous year, and to such a balance on the year's working as will not only provide for a sufficient depreciation of the undertaking for the year now entered upon, but also wipe out the debit balance on the operations of the year now closed. Subject to the modification of the power rates to long-hour consumers, which was approved by the Corporation on March 19 last, and possibly an alteration of the public street-lighting rates, a subject which is presently under consideration of a special sub committee, the committee recommend that the charges during the year 1903-4 for the various supplies of current should remain the same as last year. The quantity of electricity sold to private consumers during the past year was 10,419,488 units, as compared with 8,384,696 units during the previous year, being an increase of 24·27 per cent. The number of consumers at May 31 was 7,013, as compared with 5,374 the previous year, being an increase of 1,639, or 30·49 per cent. during the year. There were 237 consumers who consumed the equivalent of five hours or more per day of their maximum demand throughout the year, the consumpt under this head amounting to 1,696,103 units in all. The number of motors in use and supplied off the Corporation mains as at May 31 was 1,059, with a total horse-power of 4,597, as compared with 682, with a total horse-power of 3,086, the previous year. The number of units consumed for power purposes was 1,560,509 units. The total number of arc lamps erected and in regular use in the streets as at May 31 was 719, as compared with 500 the last year, and the quantity of electricity consumed for street and stair lighting was 1,081,836 units, as compared with 897,347 units during the preceding year. The number of 8-c.p. lamps, or the equivalent in other devices applied for, connected to the mains at May 31 was 630,708, as compared with 491,306 at the corresponding date the previous year, being an increase of 139,402. The number of units consumed by private consumers, per lamp fixed, averaged out month by month, according to the date of connecting up, was 19·13, as compared with 20·04 the previous year. The maximum load during the year occurred on Dec. 22 last, when it was 9,371 kw., as compared with 7,950 kw. the previous year, being an increase of 18 per cent. Contracts have been entered into for the erection of permanent brick stores and workshops at Port Dundas station, together with a complete boundary wall on three sides of the site, to take the place of the temporary wooden erections, which are now insufficient to meet the requirements of the department. These several works are now being proceeded with, and it is expected that the new buildings will be ready for occupancy in the spring of next year. The steam plant in Port Dundas station has not been increased during the year and consequently the total indicated horse-power in this station remains at 12,100, but a new set of condensing plant for the two large engines has been added and set to work. Automatic coal-weighing machines have also been installed during the year, and have been found of great service. Some of the economy in the fuel account, which has been already referred to, is attributable to their use. The other plant which was installed towards the close of last year is the induced-draught plant, which is of great assistance in meeting sudden heavy demands in foggy weather, and in providing steam economically for the peak load of the winter afternoons. The economisers, which were added before the close of last year, have also proved of great assistance in giving economical results. At Pollokshaws-road station no addition was made to the 4,400 h.p. noted in last year's report, but there is at present being installed, under a satisfactory arrangement with the contractors, a 750-h.p. engine with two dynamos in place of two 200-h.p. engines and dynamos In Waterloo-street station the steam plant has now been permanently shut down, but six of the largest dynamos there will be used in connection with the supply to be taken from the tramways department during the coming winter. The total available horse-power of the steam plant in the stations as at the close of this financial year was, therefore, 17,580, but before the winter demand comes on, the 750-h.p. engine now being erected at Pollokshaws-road and the further supply from the tramways department will be available, and will bring up the horse-power of the whole undertaking to 22,330. Under the arrangement entered into with the Corporation tramways department on April 10, 1902, by which a supply during the heavy demand experienced in the winter afternoons can be given from some

Digitized by Google

of the spare plant of that department, 150,096 units were taken at Pollokshaws-road works at a total cost of £1,007. 10s. 4d. A further arrangement has this year been entered into with the tramways department by which an additional supply will be given from Pinkston-station into Waterloo-street station at a pressure of 6,500 volts, and be there transformed by induction motors, in connection with the six existing dynamos before mentioned, to a pressure of 500 volts. The subject of hiring out of motors, powers for which have been conferred by Parliament on the electricity department, as noticed in last year's report, is now under the consideration of a special sub-committee, who hope to be able to furnish a report thereon at an early date.

Below we give abstracts for the accounts for the year ended May 31 last, the capital expenditure on which date totalled to £1,041,745.

Dr. Revenue Account.	£	s.	d.

TRADE NOTICES AND NOVELTIES.

Rectifiers.

We have received from Messrs. Siemens Bros. and Co., Limited, 12, Queen Anne's-gate, Westminster, S.W., a pamphlet dealing with a type of rectifier (Koch's system) supplied by them for transforming alternating into direct current. The principle of the apparatus is described as follows: In rectifying an alternating current of any ordinary periodicity by means of a commutator rotating synchronously

Fig. 1.

with it, a pulsating direct current is produced of the form shown in Fig. 1. If this current is used for charging accumulators, the "makes" and "breaks," occurring twice in each alternating period, must be so timed as to close the circuit and keep it closed only when the impressed voltage exceeds that of the battery, in which case the charging current will assume the form shown by the full-

Fig. 2.

full-lined curve in Fig. 2, the line *a b* indicating the voltage of the battery. In actual work, however, it is practically impossible to effect the "makes" and "breaks" with a rotating commutator at the instant when the impressed voltage equals that of the battery, and for that reason the rectification of heavy currents by such means causes excessive sparking at the contacts, requiring constant supervision and entailing great loss of

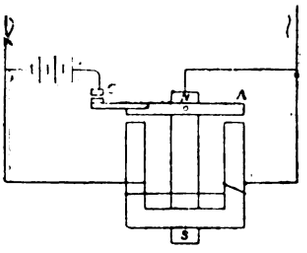

Fig. 3.

efficiency and quick destruction of the commutator. Koch's rectifier consists of a vibratory synchronous interrupter resembling in external appearance a polarised relay constructed for heavy currents and quick action. The arrangement is shown diagrammatically and in principle in Fig. 3. If the polarised interrupter is excited by an alternating current of any ordinary periodicity, its armature, A, if of suitable design, will vibrate

Digitized by Google

synchronously with the phase of the current, and the current entering by contact C, which is of like phase, will be interrupted and restored once in each period. Owing to the self-induction of the coils of the interrupter, the hysteresis of the iron and the inertia of the armature, the phase of the armature lags behind the phase of the current as shown in Fig. 4. The con-

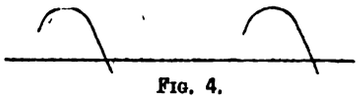

FIG. 4.

tacts may, however, be rendered sparkless by putting in series with the coils of the interrupter a condenser, G (Fig. 7), of such a capacity as not only to neutralise the self-induction of the coils, but to bring the phase of the exciting current in advance of that of the main current. This counteracts the hysteresis of the iron and the inertia of the armature and gives the curve of current the form shown in Fig. 5—viz., that of a pulsating intermittent current in which the "makes" and "breaks" occur exactly at the zero points. To make the rectified current serviceable for charging accumulators, the magnets of the interrupter must be provided with a second winding, so connected up to the battery that the

FIG. 5.

voltage of the latter opposes the current induced by the charging impulses. If this secondary winding is properly proportioned, only the excess voltage closes the contact against the potential of the battery, and an entirely automatic adjustment of the interrupter for all battery voltages is obtained. To avoid the troublesome "tuning" of the condenser, it is better to use one of relatively small capacity and to correct the excessive lead resulting therefrom by placing in the circuit a phase regulator, H, consisting of a coil of variable self-induction. The interrupter can be easily made sparkless by adjusting the position of the core of this bobbin, and it maintains its sparklessness when the fluctuations of potential

FIG. 6

in the alternating circuit are very considerable. If the potential of the battery approximates to the mean potential of the alternating current, the "closed" period is very short compared with the "open" period, and the armature, therefore, has a very jerky motion, liable to cause interruptions. To remedy this, a choking coil, D, of a moderate inductance, may be inserted between the alternator and the apparatus, which, having practically no effect upon the very weak current flowing in the exciting circuit during the "open" period, causes during the "closed" period—*i.e.*, during the period of load—a displacement of phase in the whole apparatus, and, therefore, a distortion (lengthening) of the charging impulse with respect

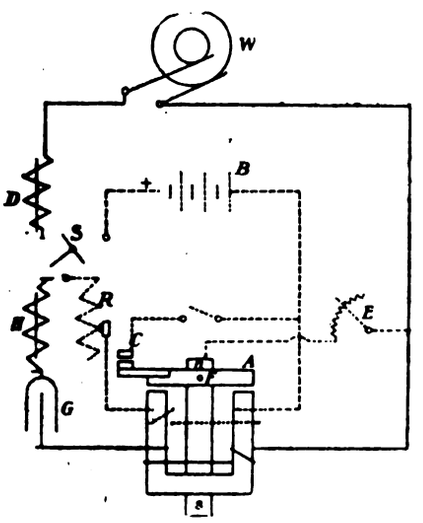

FIG. 7.

to time. Fig. 6 shows the shape of the curve of current with and without the use of the choking coil, the application of which, as will be seen, produces "open" and "closed" periods of the same length of time. Since the choking coil is placed in series with the apparatus, it affects during the "closed" periods the main and exciting currents in exactly the same way. The efficiency of the apparatus is the greater the nearer the potential of the battery equals the mean of the potential of the alternating current. Fig. 7 is a diagrammatic illustration of the apparatus, in which the dotted lines show the direct-current circuit; W is an alternator, D a choking coil, S a three-pole switch which closes simultaneously the circuit to the positive pole of the battery, B, and to the magnet coils of the interrupter. It also puts the secondary coils of the magnet in circuit with the battery. E is a starter, F the pivot of the armature A, and C the contact of the interrupter. R is an adjustable resistance, G the condenser, and H a phase regulator with variable self-induction. Following the above description are illustrations and particulars of some of the rectifiers which have been constructed on this system for charging batteries, working induction coils, and other purposes. With these we hope to deal in a subsequent issue.

Simplex Conduit.

From the Simplex Steel Conduit Company, Limited, Westinghouse Building, Norfolk-street, Strand, W.C., we have received a copy of their abridged price-list, just issued, with which is bound up a reprint of the new Institution of Electrical Engineers' wiring rules. This list is issued in conjunction with the firm's 200-page 1903 catalogue. It contains all prices in a con-

IG. 1.

FIG. 2.

densed form, with reduced illustrations. We note that two additional types of conduit are now listed to meet special requirements—viz., Simplex "Wireduct" and Simplex "Solid-Drawn" conduits, pp. 4 and 5. The first of the illustrations herewith shows one of the firm's lampholder fittings, with rosette attached; and the second their hand lamp for car-sheds, inspection pits, etc.

LEGAL INTELLIGENCE.

STEWART ELECTRICAL SYNDICATE.

Sitting as vacation judge on Wednesday, Mr. Justice Walton heard the case of Wells *v.* the Stewart Electrical Syndicate, Limited. It was a motion which was before his Lordship at the last sitting in a debenture-holder's action for the appointment of a receiver and manager. The syndicate was registered in 1896, and under their powers they, in October, 1898, issued a debenture bond for £2,200, which is held by the plaintiff. On May 18 a resolution was passed for winding up, and Mr. G. S. Pitt was appointed as liquidator. As creditors were pressing, plaintiff asked that a receiver and manager be appointed, and the syndicate consenting his Lordship made the order, subject to the usual security.

Mr. Galbraith, for the plaintiff, said they were now in a position to treat the motion as trial of the action. He asked that his Lordship should make an order in the terms of the agreed minutes, and make a declaration to the effect that the plaintiff and other debenture holders were entitled to certain debenture charges. The company was in liquidation, and the gentleman who was appointed last week as receiver and manager, acting as liquidator, consented to the order asked for.

His Lordship granted the motion.

SPEED OF TRAMCARS.

On Saturday four drivers in the employment of the London United Electric Tramways Company appeared at West London Police Court to answer adjourned summonses taken out by Mr. Moffat Ford, managing director of the Motorcar Company, for driving their cars at a speed exceeding the 10 miles an hour limit laid down in the Board of Trade regulations.

At the first hearing of the case it was contended that the Board of Trade were not empowered to make regulations as regards speed, but Mr. Muir, for the tramways company, now stated that the defence raised no point of law.

Mr. Ford stated that he timed the cars with a stop-watch over a measured distance of a furlong, and found they were going from 15½ to 17 miles an hour. He had previously gone to the police, but they refused to co-operate with him, telling him that they had had experience of the electric cars for two years, and considered that they were being run with perfect safety.

In cross-examination by Mr. Muir, the witness admitted that he himself had been convicted of driving his motorcar at an excessive

Digitized by Google

speed. He had on occasion considered that he was convicted unjustly, but he had never gone into the witness box to refute the police evidence. His object in taking out the present summonses was to make the cars go at the speed laid down in the Board of Trade regulations, and then the man in the street would be able to appreciate what a snail's pace 10 miles an hour really was.

Mr. Muir: Then your real ultimate object is to increase the speed of the cars?

Mr. Ford: My object is to make the company go at the regulation speed.

Mr. Muir, in defence, said the tramway company could conclusively prove that none of the cars timed by the prosecutor could go at a greater speed than 13 miles an hour, and he suggested that an independent test might be made by an official of the Board of Trade for the benefit of the Court.

The **Magistrate** said the matter was an important one, and he thought the learned counsel's suggestion a good one. He adjourned the summonses in order that an official test might be made.

POWERS OF A TELEPHONE COMPANY.

Judge Lumley Smith, K.C., has delivered a considered judgment in the City of London Court in an action brought by Mr. Henry Lazarus, of The Hermitage, Bushey Heath, against the National Telephone Company for damages for wrongfully cutting off his telephone service. According to the plaintiff's case, he became a subscriber three years ago to the defendants' service for one year, and he paid a fixed rent charge of £3. 10s. a year. The company wanted to introduce a new method of payment, and as the plaintiff would not agree the service was cut off.

His Honour said in his opinion the approval of the Telephone Company was requisite at the commencement of each year to enable the hiring to continue. The defendants did not approve of a continuance after the third year, and were not bound to continue. No notice was stipulated for, but as the Telephone Company had decided to make a change in their terms a considerable time before the expiration of the third year, they might reasonably have given the plaintiff more than the few days' notice which they did give him. The action failed, but he would give leave to appeal. As the legal aspect was doubtful, he should order each party to pay their own costs.

COMPANIES' MEETINGS AND REPORTS.

GEORGE M. CALLENDER.

The statutory meeting of the shareholders in this Company was held at the Westminster Palace Hotel, Victoria-street, S.W., on the 20th inst., Mr. George M. Callender presiding.

The **Chairman,** addressing the shareholders, said the Company's prospectus was publicly advertised on April 6 and 8 inviting applications for an issue of 25,000 6 per cent. cumulative preference shares. The total amount received on account of the shares to the date of our report—namely, July 25—was £18,941, leaving £6,059 still to be paid at that date. Since then a substantial sum had been received, and it was expected that by the end of the present month there would be nothing outstanding. Owing to the receipt of some special cablegrams from South Africa with reference to important business to be done by them in that part of the world, it was decided that he should proceed there immediately after the allotment, which he did, and he only arrived home on Saturday last. During his absence it was thought advisable that another London director should be added to the Board, and after careful consideration and mature deliberation, Mr. Allan Greenwell, A.M.I.C.E., a well-known engineer, was appointed to that position, and his services during the last three months had been of great benefit to the Company. The prospects of business in South Africa were very encouraging, but at the moment the financial condition of that country did not warrant any extensive outlay. Apart from this, he thought that as soon as the controllers of the large mining groups on the Rand saw their way to start work on the large number of mines which had been closed down, there would be a great deal of work for them to do there. All the gold mines on the Rand were forced to have reservoirs and cooling ponds for conserving the water required for the cyanide. The sales of their pure bitumen damp-course had been moving along in a perfectly satisfactory manner. The new works at Bow had been delayed in their completion. However, the principal building would be ready for occupation this week, and they were now making arrangements for transferring the necessary plant from Callender's Cable and Construction Company's works at Belvedere, Kent, to their works at Bow. Concluding, the chairman said they were now in a position, not only to line reservoirs, but also to take over the whole work of constructing and maintaining same, and several works of this nature had been carried out, and had resulted in increased profit to the Company.

The proceedings terminated.

TYNESIDE TRAMWAYS AND TRAMROADS.

The half-yearly meeting of the shareholders in this Company was held at the offices, Newcastle, on Monday. Lord Armstrong presided.

The directors' report stated that the surplus of receipts over expenses amounted to £1,198. 7s. 6d., which, together with the balance carried forward from last year—viz., £233. 5s. 9d.—made a total to the credit of the profit and loss account of £1,431. 13s. 3d. Out of this the directors proposed the payment of a dividend at the rate of 2 per cent. per annum, less income tax, which would leave £326. 18s. to be carried forward. The extension between St. Nicholas Church and the High-street, Gosforth, was opened for traffic on April 10. As the extension of the Newcastle-upon-Tyne Corporation tramways along Shields-road from Heaton to the Wallsend boundary had only been completed for a few weeks, it was too soon to come to any conclusion as to the effect it might have upon the Company's lines. The traffic receipts showed a steady and satisfactory increase. The directors had authorised the construction of the line along the North-road to Gosforth Park, and for this work plans and specifications were now being prepared.

The **Chairman** moved the adoption of the reports. He thought they would agree with him that the balance-sheet of this, their first complete half-year of operation, was a satisfactory one, and indicated material progress. Regarding the question of interchange of traffic, he was glad to say that the Tynemouth Tramways Company had now obtained a Bill to enable them to lay a third rail from Borough-road to the Company's terminus, thus facilitating the transference of passengers from this system to theirs and *vice versâ*. With regard to Newcastle, on the other hand, it was common property that the Corporation of Wallsend had called upon their Company, in pursuance of an arrangement made with them when they were making application for the first Bill, to enter into active negotiations with the Corporation of Newcastle for mutual running power, and if these could be otherwise obtained to endeavour to get parliamentary powers for them in the ensuing session. This Company had informed the Corporation of Wallsend that they had been for some time past in active negotiations on the subject with the Corporation of Newcastle, and they had every hope that the matter might be concluded to the advantage of both the Newcastle Corporation and this Company, without the necessity of any parliamentary interference. For the future, without venturing to prophesy, he might say that there was every reason to hope that they would continue to make steady and material progress.

Dr. Merz seconded, and the resolution was carried unanimously.

The **Chairman** moved that a dividend of 2 per cent., free from income tax, be declared.

Mr. J. H. Armstrong seconded, and the resolution was also carried *nem. con.*

DUBLIN AND LUCAN ELECTRIC RAILWAY.

The ordinary half-yearly meeting of the shareholders in this Company was held at the Company's offices, Mr. James Wm. Hill, J.P., presiding.

The **Chairman,** in moving the adoption of the report, said that, as compared with the corresponding period of last year, there was an increase in the receipts of £60 from passenger and £80 from goods traffic. There was a decrease in parcels and sundries of £17. The net increase was about £61. The expenditure showed an increase in the maintenance of way of £39, of motive power of £71 and the other items of carriage and wagon repairs brought the total increase to £217. If the summer had been favourable there would have been a very considerable increase of receipts, but as it was, they ought to be satisfied that they had fully held their own, and were able to show an increase—even slight.

Captain Charles Colthurst-Vesey seconded the adoption of the report, which was unanimously carried.

The **Chairman** proposed and **Mr. William F. Clarke, C.E.,** seconded a resolution declaring that a dividend of 5 per cent. per annum be paid on the preference shares.

The resolution was adopted.

BLACKPOOL AND FLEETWOOD TRAMROAD.

The half-yearly meeting of the shareholders in this Company was held on Thursday afternoon last week, Mr. Geo. Richardson presiding.

In moving the adoption of the report and balance-sheet, the **Chairman** said he thought the shareholders would agree with the Board that they were very satisfactory. They had carried for the half-year 789,020 passengers, an increase of 109,280. The receipts from all sources were £10,748. 3s. 1d., as against £9,940. 19s. 4d., being an increase of £807. 3s. 9d. On turning to the revenue account they found an increase in income of £789. 2s. 8d., but on the other side there was an increase in expenses of £473. That was accounted for by a compensation case in which £300 had been paid, and also by an increase in the amount of rates and taxes.

Mr. Barningham seconded, and the resolution was carried unanimously.

NEW COMPANIES REGISTERED.

International Sprinkler Company, Limited.—Capital, £100. Object: to carry on the business of mechanical and electrical engineers, etc.

Carlton Motor Company, Limited.—Capital, £800. Objects: to manufacture and deal in motors, cycles, automobiles, and locomotives or stationary engines of every description, and to carry on the business of electrical engineers, manufacturers of, dealers in and generators, storers and suppliers of electrical and other power, etc.

Sybry, Searls, and Co., Limited, Cannon Steelworks, Sheffield. This business, which was established more than half a century ago, has been converted into a private limited liability company. The managing directorship has been taken up by Mr. Victor F. J. Tlach, for many years intimately connected with Messrs. Bohler Bros. and Co., Styrian Steelworks, Sheffield, and he will be joined on the Board by Mr. Edward C. Ibbotson, F.C.S., who will undertake the management of the works.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Macao.—The Colonial Office at Lisbon invite tenders for the electric lighting of Macao. Tenders by Oct. 21.

Lisbon.—The Public Works Department require tenders for the public electric lighting of Macao. Tenders by Oct. 21.

Queensland.—The Deputy Postmaster-General at Brisbane invites tenders for the supply of material for the postal and telegraph service by Sept. 30.

Paris.—The Post and Telegraph Department, Rue de Grenelles 103, invite tenders for (1) 190,000 ko. bronze or copper wire and 94,000 joints, and (2) 12 kilometre submarine telegraph cable.

Beszterezehanya (Neusohl, Austria).—Tenders are required by the municipality for installation, buildings, etc., of a central station of a minimum capacity of 600 h.p. Tenders by Aug. 31.

Kirkealdy.—The Corporation invite tenders for supply of all fittings for installing the electric light into the memorial halls in Bennochy-road. Tenders by Sept. 12. See advertisement.

Madrid.—The Post and Telegraph Department require tenders for a telephone system in communication with the principal central station in San Lorenzo del Escorial and sub-central stations in Cercedilla. Tenders by Sept. 6.

Dublin.—The Port and Docks Board invite tenders for the supply of a 100-ton electric crane. Specification can be obtained at the office of the engineer to the Board, Mr. John P. Griffith, M.I.C.E., Eastwall, Dublin. Tenders by Oct. 5.

Hackney.—The Council invite tenders for arc lamps and pillars and distributing mains. Forms of tender, etc., may be inspected at the office of Mr. Robert Hammond, M.I.C.E., 64, Victoria-street, Westminster, S.W. Tenders by 4 p.m. on 31st inst.

Linlithgow.—The County Council invite tenders for lighting the Uphall special lighting district by electricity. A plan will be exhibited in the office of Mr. J. G. B. Henderson, district clerk, Linlithgow, from whom all particulars may be obtained.

Worthing.—The Corporation invite tenders for the reconstruction of their storage battery at the electricity works. Specification of the work can be obtained from Messrs. Burstall and Monkhouse, 14, Old Queen-street, Westminster. Tenders by Sept. 7. See advertisement.

Shanghai.—The French Colony propose to instal motor-propelled tramways. Tenders may be sent by Oct. 31, 1903, to Secrétariat de la Municipalité Française de Shanghai. Particulars may be obtained from l'Office National du Commerce Extérieur, Rue Feydeau, 3, Paris.

Russia.—The Russian Minister of the Interior has sanctioned a plan for the reconstruction of three lines of municipal tramways—namely, those in Newsky, Sadovaïa, and Wassiliostrow districts. Each car is to provide for two classes of travellers, and will accommodate 52 persons.

Utrecht.—The Town Council will receive tenders for supply and erection of a central electric establishment for lighting, power supply, and working tramways. Contract, conditions, etc., to be obtained at the "Gemeente Secretaire" of Utrecht, on payment of 5fl. (8s. 4d.). Tenders by Oct. 1.

Radcliffe.—The Urban District Council invite tenders for the supply and laying of tramway and lighting feeders, distributing and pilot cables, conduits and accessories. Specification, etc., may be obtained from Mr. S. Mills, clerk to the Council. Tenders by Sept. 5. See advertisement.

Southend-on-Sea.—The Corporation invite tenders for steam dynamo, boiler, and condenser. Specification, etc., may be obtained from Mr. W. E. J. Heenan, M.I.E.E., borough electrical engineer and general manager, Southend-on-Sea. Tenders by noon on Sept. 14. See advertisement.

Bermondsey.—The Borough Council invite tenders for the erection of buildings in connection with extensions to the dust destructor house, electric light station, boiler-house, etc., at the Council's works near of town hall. Specifications, etc., can be obtained at the Town Hall, Spa-road, S.E. Tenders by Sept. 8.

Launceston (Tasmania).—The Mayor and Aldermen invite tenders for the supply of 500 or more electric meters. Particulars may be obtained on application to Mr. William Corin, city electrical engineer, Launceston, Tasmania, or to Messrs. John Terry and Co., 7, Great Winchester-street, London, E.C. Tenders by Sept. 28.

Madrid.—Tenders are invited for a concession for a telephone system with a central station at Palamós and subsidiary stations at San Feliú de Guixols and Palafrugell. A deposit of 2,000 pesetas is required, and tenders must be presented within 30 days from Aug. 14 to the Registry of the Directorate of Posts and Telegraphs, 10, Calle de Carretas, Madrid.

Manchester.—For the supply of points and crossings, for the Tramways Committee. Specifications, etc., may be obtained from Mr. J. M. M'Elroy, general manager, Tramways Department, 55, Piccadilly, Manchester. Tenders, addressed to the Chairman of the Tramways Committee, 55, Piccadilly, Manchester, must be received by 1 p.m. on 29th inst.

Pietermaritzburg.—The Corporation invite tenders for the supply, delivery, and erection of the necessary poles and overhead equipment for about 5¼ miles of tramway route. Specifications may be seen at Messrs. Mordey and Dawbarn, 82, Victoria-street, S.W. Tenders to Messrs. Ford Bros., 12, Southampton-street, Fitzroy-square, W., by Sept. 7 (noon).

Edinburgh.—The Council invite tenders for the following works in connection with the proposed extension of Macdonald-road electric power station; (1) building works, including excavator, mason, brick, joiner, slater, plasterer, plumber, and glazier's work; and (2) smith and ironfounder's work. Tenders must be sent to Mr. R. Morham, city architect, by 10 a.m. on Sept. 14.

London, S.E.—The London County Council invite tenders for the supply, delivery, and erection in the electricity generating station to be established by the Council at Greenwich of four 5,000-h.p. vertical-horizontal steam-engines, each suitable for driving a three-phase generator. Particulars, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 6.

Batley.—The Corporation invite tenders for the mason, joiner, plumber, plasterer, slater, painter, heating engineer, and electric lighting engineer's work respectively, in erection and completion of additions to the present town hall. Plans and specifications, etc., can be seen, and bills of quantities obtained at the offices of Messrs. Walter Hanstock and Son, architects, Branch-road, Batley. Tenders to be sent to Mr. J. H. Craik, town clerk, by noon on Sept. 4.

Birmingham.—The Tramways Committee require the names of contractors who are desirous of tendering for the supply and delivery of materials and fittings as follows: (Section A) manganese steel points and crossings; (B) tapered steel side poles and bracket arms; (C) suspension ears, pull-offs, section insulators, and other overhead materials; (D) hard-drawn copper trolley wire and stranded steel span wire. Mr. John Price, city engineer, Council House, Birmingham.

Stoke-upon-Trent.—The Corporation invite tenders for the supply and erection of the following plant in connection with the proposed electricity and destructor works: (Contract 10, Section A) pipework; (B) non-conducting covering; (C) water-softening plant. Persons are at liberty to tender for any single section. Specifications, etc., can be obtained from Mr. P. J. S. Tiddeman, Field-place, Stoke-upon-Trent. Tenders to Mr. Jno. B. Ashwell, town clerk, Town Hall, Stoke-upon-Trent, by 5 p.m. on Sept. 11.

RESULTS OF TENDERS.

Bray.—The Urban District Council have accepted the tender of Mr. Fraser for bridging culvert at electric light works, at £22. 5s.

Grimsby.—The tender of Messrs. Hewins and Goodhand for the building of the new sub-balancing stations in Riby square for £589 has been accepted.

London.—The British Thomson-Houston Company have received the contract for the entire electric control equipments of the Metropolitan District Railway.

Aberdeen.—The County Council have accepted the tender of Mr. J. F. Anderson, at £109, for the work of fitting up the County Buildings with electric light.

Cardiff.—The tender of Messrs Beames and Nephew, Violet-row, at £1,972. 10s., for new electrical department for lupus treatment, etc., at the infirmary, has been accepted.

Dewsbury.—The Town Council have accepted the tender of Messrs. Robb and Mitchell, Ossett, at £634. 17s. 4d., for electric mains and switchboard at the new infectious diseases hospital.

Brighton.—The Town Council have accepted the tender of the Reason Manufacturing Company, Lewes-road, for the supply of meters for one year from Sept. 1, at £2. 5s. per meter for siphon-tube type, and £1. 17s. for single-tube type.

Ipswich.—The Town Council have accepted the tenders of the British Westinghouse Electric and Manufacturing Company for the supply of a combined motor watering and track-cleansing car at £864. 6s., and for a telescopic car and breakdown wagon at £70.

Crete.—Several tenders have already been received for the electric lighting of Canea, including one from a German resident in the town, specifying not only the electric lighting of Canea, but also an electric train between Canea and Halepa, and a possible extension to Suda.

BUSINESS NOTES.

TRACTION.

Bournemouth.—The Corporation Tramways Bill has received the Royal assent.

Axminster and Lyme Regis Light Railway.—This line was opened on Monday.

Brighton.—It is proposed to lay tramways at an early date on the Dyke-road and North-road routes.

Tanat Valley Light Railway.—Monday, Oct. 1, has been provisionally fixed for the formal opening of this railway.

South London.—The electrification of the London County Council tramway through Southwark to Greenwich is now rapidly approaching completion.

Keighley.—The Tramways Committee suggest that double lines be laid the whole length of the route in the reconstruction and extension of the tramways to Stockbridge.

Rochdale.—The negotiations between the local authorities and the Bury, Rochdale, and Oldham Tramways Company are reported to have ended without an agreement having been come to.

Bradford.—Mr. Spencer, the manager, has submitted proposals, which have been approved by a sub-committee, with a view to meeting certain grievances which the men desire remedying.

Central Wilts.—The Light Railway Commissioners are expected to hold an enquiry at the end of September or the beginning of October into the application for a light railway order for this district.

London County Council Tramways Manager.—Over 100 applications have been received by the London County Council for the vacant post of manager for their tramway system in South London.

Digitized by Google

Leeds.—The Tramways Committee are encouraging their motormen to drive carefully, having decided to give all drivers who avoid accidents a bonus of ½d. per hour in addition to their wages, payable quarterly.

Leith.—A large meeting of merchants was held on Thesday afternoon, when a resolution was passed by an overwhelming majority urging the Town Council to complete the purchase of the tramway system in the burgh.

Audenshaw.—The work of laying the track for the electric cars from Audenshaw to Ashton is proceeding satisfactorily, and in a very short time there will be a thorough system of electric trams from Ashton to Manchester.

Rowley Regis.—The Light Railway Commissioners have submitted to the Board of Trade for confirmation an order made by them for the construction of light railways in the urban districts of Quarry Bank, Brierley Hill, and Rowley Regis.

Wrekenton.—Considerable interest has been aroused in the district by the running of a trial tramcar. The lines are almost completed; only the sidings want finishing. It is expected that the trams will be in full swing early in September.

Ilford.—During the week the first of the roofed tramcars which are to be introduced to London by the District Council will be running. The covers are of wood, with glass ends and movable glass sides. Smoking is to be permitted within the structure.

Aberdeen.—The Town Council have by 22 votes to 8 adopted the Tramways Committee's report, recommending that ½d. fares should be introduced in Union-street in two blocks—from Castle-street to Crown-street and from Crown-street to Holburn-street.

Birkenshaw.—It was reported at the last meeting of the District Council that the British Electric Traction Company had placed the order for the construction of the lines in Birkenshaw, and that they had agreed to use granite setts for the paving in the district.

Motorcabs.—The London Express Motor Service, Limited, have decided to place 50 motor-driven hansom cabs on the streets of London in about three months' time. The new cab has a 12-h.p. petrol motor, and is geared to travel at a speed not exceeding 24 miles an hour.

Lowestoft.—Since the opening day (July 22) the trams have carried 396,859 passengers, and the receipts have been £1,909. 3s. 4d. Last week's receipts amounted to £363, and 79,708 passengers were carried, a slight falling off from the previous week's figures, due to the bad weather.

German Rails.—A councillor has given notice of a motion which he will move at the next meeting of the Birmingham City Council in October, regretting that the Tramway Committee have thought it necessary to purchase tramrails from abroad at a time when the British industries need support.

Southsea.—The abnormal downpour of rain at the beginning of the week was responsible for considerable dislocation of the electric tramway traffic, several of the main streets being flooded. On some routes the service had to be temporarily stopped, and on others a through service was only maintained with difficulty.

Italian Railways.—A Rome correspondent says that the railway between Milan and Varese has been adapted for electric working, and a few experimental runs have been made at a speed in places of 72 miles an hour. The Mediterranean Company is shortly to establish a regular service covering the distance in 45 minutes.

Kirkcaldy.—The new electric cars for the extended route have now been delivered, and are running at intervals on the initial route with satisfactory results. The cars, five in number, are slightly different in construction from those previously running. The new route is expected to be opened about the middle of October. The route will be lighted by arc lamps.

Inquest.—Mr. J. F. Price, county coroner, has held an enquiry into the circumstances attending the death of Robert Smith, a child three years of age, who was killed by an electric car in Failsworth on Sunday night. The jury returned a verdict of accidental death, suggesting that the Corporation should be recommended to have more effective guards on the cars.

Bury.—A special meeting of the Town Council has been held for the purpose of passing a resolution authorising notice to be given to the Bury, Rochdale, and Oldham Tramway Company requiring the company to sell those portions of their undertaking within the borough which were authorised under the extension order of 1882. The resolution was adopted.

West Cumberland.—At the last meeting of the Egremont Urban District Council the clerk said he had received a copy of the West Cumberland Tramways Act. They petitioned against the Bill, and he was pleased to say the clauses that they agreed upon had been inserted. They might look upon it as very satisfactory. They had reduced the charge for electricity from 7d. to 3d. per unit.

Paris Metropolitan.—A Paris telegram dated Aug. 21 states that a short-circuit occurred on the Metropolitan Railway the previous night on train No. 48, which was one of those concerned in last week's disaster. As soon as the defect was noticed the train was emptied, but most of the passengers, instead of waiting for the next train, left the station, preferring to continue their journey by omnibus.

Glasgow.—A mass meeting of Corporation tramway workers was held at midnight on Saturday to discuss the refusal of the Tramways Committee to recognise the union and the rejection by the committee of the application by the men regarding working hours and extra payment for Sunday labour. Resolutions were adopted in favour of again approaching the committee urging them to recognise the union.

Rio de Janeiro.—Dr. Carlos Cesar de Oliveira Sampaio and Antonio Julio de Oliveira Sampaio have obtained a concession for the construction and working of a metre-gauge underground electric railway from Rio de Janeiro to Nitheroy. Amongst the provisions of the concession is the exemption from import duties of the material for the construction of the railway and for the first three years of its working.

Eastbourne.—Already two motor 'buses of the Milnes-Daimler type are running on the streets of this fashionable seaside resort, and another vehicle was expected to be delivered this week. A fourth 'bus may be expected shortly, the Electric Lighting Committee having arranged with the company for its early delivery. The new 'buses will have twin tyres, the single tyres on the first vehicle not having proved altogether satisfactory.

Dewsbury.—The electric cars from Dewsbury to Cleckheaton market-place, *via* Heckmondwike and Liversedge, have commenced running. At a meeting of the General Purposes Committee it was stated that after conferences of representatives of the Dewsbury and Ossett Corporations and the Soothill Nether District Council, a proposal in favour of constructing an electric tramway between Ossett and Dewsbury had been agreed upon.

Heywood.—A special meeting of the Town Council has been called for Sept. 28 for the purpose of taking into consideration a resolution that so much of the undertaking of the Bury, Rochdale, and Oldham Tramway Company, Limited, authorised by the Manchester, Bury, and Rochdale Tramways (Extension) Order, 1882, as is within the borough of Heywood shall be purchased by the Corporation on the terms specified in Section 43 of the Act.

Bankfoot Light Railway.—The Light Railway Commissioners have submitted to the Board of Trade for confirmation an order made by them reviving the powers granted and extending the period limited by the Bankfoot Light Railway Order, 1898, for the compulsory purchase of lands, and extending the period limited by that order for the completion of the railway and works by that order authorised. Objections must be lodged with the Board of Trade by Sept. 14 next.

Competition.—Mr. T. H. Jackson, speaking as chairman at the half-yearly meeting of the Wirral Railway Company, attributed the decrease in the passenger traffic to the competition of the electric tramways, through which the company had lost at least 25 per cent. of their New Brighton traffic. So far the electrified Mersey Railway had not brought them any great advantage. Mr. Jackson also hinted at the early adoption of self-propelled motors on the Wirral Railway.

Southport Railway.—The building of the transforming station which is being erected at Birkdale in connection with the electrification of the Lancashire and Yorkshire Railway line between Liverpool and Southport is now completed, and is waiting for machinery, which, it is expected, will arrive in about a fortnight. At the Formby power station the boilers are being placed in position. Gangs are working on the line itself both towards and away from Southport, and in about a fortnight the work on the line between Southport and Freshfield may be completed.

Motorcars on Railways.—The Great Western Railway Company have inaugurated a motorcar service between Helston and the Lizard. The cars are each of 16 h.p., and are known as the Constatt-Daimler, and are provided with Sims Bosch magneto ignition, with automatic inlet valve governed on the throttle. There are four gears and reverse, while the speed is from 16 to 4 miles per hour. The engine is fed with petrol from a tank at the back, capable of holding 14 gallons, sufficient for a journey of 140 or 150 miles. Each car, which costs £800, is capable of seating 20 persons, and weighs about two tons.

Northampton.—The work of converting the tramways to electr traction is being expedited as quickly as possible. The time for sending in tenders for the work expired on Saturday, and about 100 tenders have been received. The tenders cover the cost of generating stations, overhead equipment, the permanent way, the cars, cables, etc. The estimate of the surveyor (Mr. W. Fidler) in his original report on the work was that it would cost £85,000, and there is not much likelihood that this estimate will be exceeded. The Tramways Committee are not likely to arrive at a definite decision for about a fortnight.

Safety of the Tube.—Apropos of the Paris Tube disaster, the general manager of the Central London Railway has been explaining to a correspondent the safety precautions adopted on the "Twopenny Tube." We gather that it is proposed to equip the trains with telephones as an additional precaution, so that in case of accident the driver can communicate with the nearest station. It may be mentioned that the electric lighting of the tube is independent of the working current, so that in case of the current being cut off the illumination would remain. In addition, oil and gas are provided should the lighting current fail.

Electric Locomotives. — It is reported that the steamship "Roseley," which left New York recently for various South African ports, took out what will probably be the first electric locomotive to enter the "Dark Continent." The locomotive, which was manufactured by the C. W. Hunt Company, of West New Brighton, N.Y., is shipped to the order of the De Beers Consolidated Mines, Limited, for use on one of their plants. The locomotive, says *South African Exports*, is of the latest storage battery type, standard throughout, with the exception of the gauge of the wheels, which is special, to suit the track now in use at the mines.

Additional Traffic Returns.—Anglo-Argentine, £1,644 increase; Barcelona Ensanche y Gracia, £205 increase; Barcelona, £122 decrease; Brisbane, £34 increase (month of July, £10,160, increase £4); British Columbia Electric (month of March), gross earnings £10,352, net income £2,658; Buenos Ayres and Belgrano Electric, £322 increase (month of July, £13,269, increase £1,142); Calcutta, £471 increase; Cape Town (month of April), receipts £16,003, expenditure £8,313; Isle of Thanet Electric, £153 decrease; Mexico Electric (month of June), receipts £46,270; Perth Electric, £122 increase; Port Elizabeth (month of April), receipts £4,292, expenditure £2,281.

Digitized by Google

Marlborough.—Upwards of £2,000 has been guaranteed in Marlborough and district towards the cost of the proposed light railway from Calne to Marlborough. The scheme is so framed that the line from Marlborough to Hungerford may be dropped if necessary. The Light Railway Commissioners are expected to hold their enquiry at the end of next month. Mr. Cecil Brown, the engineer, has succeeded in making an amicable arrangement with the landowners. The estimated cost of the line per mile from Calne to Marlborough is £10,500. An assurance has been given that providing the order is obtained there will be no difficulty in finding the capital.

Greenwich.—Addressing the shareholders at the half-yearly ordinary meeting of the London, Deptford, and Greenwich Tramways Company on Tuesday, Mr. George Ennis, alluding to the sale of the undertaking to the London County Council, stated that Sir Frederick Bramwell had been appointed arbitrator by the Board of Trade to settle the price to be paid by the County Council under Section 43 of the Tramways Act, 1870. It was expected that Sir Frederick, in whom both parties had every confidence, would hold his court in October, but no definite date had as yet been fixed. The Board would convey to the shareholders the rough result of the hearing at the earliest possible date, and at the next meeting they would, it was anticipated, be able to announce what the proprietors might expect to receive in the way of the return of capital.

Upper Norwood.—After opposing the introduction of tramways when first mooted, the people of Upper Norwood have suddenly changed their view, and are now clamouring loudly for their introduction. A canvass of the district recently made resulted in a majority of more than three to one in favour of an extension of the existing lines from Thornton Heath to Upper Norwood, and from Herne Hill to the Crystal Palace. Such extensions would put the people of the neighbourhood in tramway communication with the centre of London on one side, and with Croydon on the other, and render them less dependent than at present on a none too satisfactory train service. It has been resolved, subject to the Deptford and Lewisham Councils paying half the cost of widening the roads in their areas to proceed with the deferred tramway through Brockley from Lewisham to Forest Hill, which will also link up the Crystal Palace district by means of the South London system with Greenwich, Woolwich, and the riverside towns.

Portsmouth.—At the quarterly meeting of the Town Council the Tramways Committee presented a lengthy statement by Mr. Rotter with regard to the various tramway contracts. From this it appeared that a sum of over £27,000 had been spent in excess of the amounts originally sanctioned, and the total of the contracts was £378,425, of which £12,643. 11s. 10d. was still outstanding. Mr. Rotter's concluding remarks were as follows: "I should like to point out that this total is considerably less than my original estimate, which was for £402,050. This included an amount of £6,170 for a car-shed at East Southsea, which has not been used, and also a sum to cover general and engineering charges, alterations to pipes and mains, and other incidental works which could not be carried out under any contract nor estimated with any great degree of accuracy. The amount expended under this heading to date has been £10,306, so that, even after giving credit for these amounts, I can claim to have effected a saving of £7,149 on my estimate."

Liverpool.—A new form of cover for electric cars is being worked out by Mr. Bellamy on the lines of the original covers adopted on several of the Liverpool cars. The new cover is constructed on a framework similar to the old one, but, instead of the blinds closing in the sides of the upper deck, a series of windows is arranged which can be lowered or raised as necessity requires in the same way as the window of a railway carriage. The roof is formed of sliding wooden partitions, which are so constructed that there is no possibility of raindrops making their way through, and in bright, warm weather the sections can be opened so as to leave two-thirds of the roof of the car open. The improvement, both from the view of convenience and comfort, cannot fail to be appreciated. From the point of view of economy the improvement is also most satisfactory, as it can be fitted up at about three-fifths of the cost of the blinds formerly in use. The committee are so convinced of the utility and success of the new arrangement that they have ordered 20 cars to be fitted with it at Lambeth-road works, and these will be placed on the various routes in the city in the course of a few days.

Glossop.—The formal opening of the electric tramways took place in showery weather on Thursday last week, at noon. The lines are laid down on the single track and loop plan, and are 3½ miles in length, connecting Glossop with Hadfield, through Dinting, with a generating station between the two places. There is also a branch line of about three-quarters of a mile, running from the main route to Whitfield. The service will be a 15-minute one from the Hadfield terminus, and half-hourly from Whitfield and Old Glossop. Seven cars of the double-deck type will run. On Thursday the whole seven cars, gaily decorated, traversed the entire route, the first, or No. 1 car being driven by the Hon. Mrs. Hill-Wood, of Moorfield, who formally opened the service. Notwithstanding the heavy downpour, thousands of people thronged the streets to witness the opening. It is regarded as quite possible that in the near future Glossop will be placed in tramway communication with Manchester, a proposal having been put forward for the construction of a line connecting with the Godley and Hyde system. The tramways were opened for public traffic on Friday.

London Traffic.—At the half-yearly meeting of the London General Omnibus Company, the chairman (Mr. Alderman Pound) referred to what he called the "ill-considered schemes of municipal trading." The main question to be considered, he said, was: under what circumstances is a municipality to be allowed to go outside the province of government and enter into the arena of trade The unsoundness of the financial position created by municipalities, which had piled up debts of about 300 millions sterling on the security of the local rates, and which were increasing their indebtedness to an almost unlimited extent, had been apprehended by the controllers of the great banks. As regarded London traffic, the Alderman referred to the Royal Commission sitting on the subject, and said that on the members' return from their investigation of American traffic the omnibus traders would submit their solution of the problem of London traffic. They trusted that the members of the commission would recognise what the omnibus service had done, and could do, to facilitate intercommunication. At present the company had one motor omnibus, the license for which was under the consideration of the authorities. He trusted that at the next meeting he would be able to give the shareholders some account of its working. The two main points to consider on the subject of motors were safety and economy of working.

Birmingham.—A special meeting of the Tramways Committee was held on Wednesday, when Mr. Allen Baker, the newly-appointed engineer and general manager of the tramway scheme, was present, and was warmly welcomed. Tenders for the construction of the new tram-sheds in Elkington-street were examined. The committee also had under consideration the type of car to be used on the Aston line, and after a long discussion a definite choice was made. With regard to this point, Mr. Joseph Ansell and the engineer to the Aston Tramway Committee attended on behalf of the Aston District Council to arrange, as far as possible, for the adoption of a uniform type of car and rail in connection with the whole of the Aston route. The committee approved of a car similar in construction to that now in use on the Bristol-road route, with the exception that is is built on bogie trucks instead of on the four-wheel principle. At the close of the discussion, which lasted over two hours, Alderman Beale asked if there was anything to be said in regard to the German tramrail controversy. Mr. Beale said he could only say that the rails were being obtained from the well-known British firm of tramway contractors, Messrs. Dick, Kerr, and Co. "There is no doubt," added Mr. Beale, "that English manufacturers cannot turn out a tramrail equal to that obtainable from abroad at the price." If the City Council did not desire them to buy in the cheapest market, they must say so.

District Railway Electrification.—As will be seen from our "Tenders Accepted" columns, an important decision has been made by the Underground Electric Railways Company of London, Limited, in awarding the contract for the entire control equipments for their new electric trains on the Metropolitan District Railway to the British Thomson-Houston Company, Limited, of Rugby. The system to be employed is the Sprague Thomson-Houston multiple-unit system, with which an experimental train has been equipped on their newly-opened line from Ealing to Harrow, and on which, for over four months past, continuous experiments and competitive tests under special and normal conditions of traffic have been going on, to ascertain which of the two systems of control competing will best meet the various requirements of this railway, having due regard to the safety of passengers, reliability of control, economy of power, low cost of maintenance, comfort to passengers, and simplicity. After thoroughly weighing all these matters the contract was, as above mentioned, awarded to the British Thomson-Houston Company, Limited. It will be remembered that a somewhat similar series of tests were made before the decision was arrived at as to what system of control should be adopted on the New York underground railways, and the same system of multiple-unit train control was decided upon. This system may be considered as the universal system in use for operating electric railways, it being in use or contracted for by over 32 railways throughout the entire world, over 2,000 equipments being at present in use. The Metropolitan District Railway, in taking this step, have placed themselves in line with other English electric railways who have also adopted this system.

Fares in Glasgow.—An interesting report on the question of halfpenny tramway fares has been issued to the Corporation Tramways Committee by Mr. John Young, the general manager. As the outcome of enquiries addressed to over 50 corporation tramway managers throughout the country, he arrives at the conclusion that the opinion of the various corporations is not at present generally favourable to the adoption of halfpenny fares, although seven of them—including Glasgow—have such fares in operation over their whole systems; nine, including Leeds, Halifax, and Ilkeston, have halfpenny fares on certain stages; and four or five others issue halfpenny tickets to workmen. In Glasgow the halfpenny stage, which is about half a mile, was originally one-half of the penny stage, but subsequently the penny stage was doubled, while the halfpenny stages remained practically as they were originally fixed. Mr. Young gives figures showing that one-third of the passengers travel at the halfpenny fare, while the receipts from them are 18 per cent. Sixty-one per cent. of the passengers travel at the penny fare, the receipts from them being 69 per cent.; and 7 per cent. of the passengers travel at over the penny, the receipts from these being 13 per cent. The average fare collected per passenger at present is ·88d. Last year's accounts show that the average cost per passenger was ·75d., exactly three farthings. The profit is, therefore, only about one-eighth of a penny, which Mr. Young considers a narrow enough margin in a business of this kind. Investigation further shows, he says, that almost one-half of the penny passengers travel little more than a mile, or about the distance of two halfpenny stages. The immediate result, therefore, of doubling the halfpenny stage, as is proposed, would be to transfer about 54,000,000 million passengers from the penny to the halfpenny fare, with the consequence—taking the past year's experience as a basis—that not only would the surplus of £100,000 be wiped out, but the tramways would actually be carried on at a loss. Mr. Young accordingly recommends no change in the present stages and fares.

Huddersfield.—The Tramways Committee, it will be remembered, were recently let in for some £1,700 damages as a consequence of an accident which occurred on their electric system. They have now sought to protect themselves against liability for such large sums, and visitors to Huddersfield may observe that notices are affixed to the seats of the cars, and to various other prominent positions, attempting to put a limit to their responsibility in cases of accident on the cars, etc. The notice, which is printed on the backs of the tickets also, reads as follows: "Important notice to passengers.—Issued at reduced fares and subject to the by-laws, and on condition that in case of injury from whatever cause arising the total liability of the Corporation shall not exceed £25. Except as above passengers travel at their own risk." In order to ascertain an opinion which might be regarded as fairly interpreting the law, a local resident recently put the case before the *Justice of the Peace*. The reply given in Saturday's issue of that journal is as follows: "The local authority being the owners of the tramways, and working them, are 'promoters' within Section 55 of the Tramways Act, 1870, and are under that section 'answerable for all accidents, damages, and injuries happening through their act or default, or through the act or default of any person in their employment, by reason or in consequence of any of their works or carriages.' This being a statutory obligation, the tramway authority cannot limit their liability in the case of passengers in the manner proposed. Even apart from Section 55, the tramway authority cannot except or limit their liability for negligence." The committee have instructed the manager to make arrangements for carrying a limited number of cycles by tramcars at owners' risk. At last week's meeting of the Town Council, attention was drawn to the fact that the tramways were being subsidised from the rates year by year, the amount this year being equal to 7d. in the £ Up to last year £58,683 had been drawn from the rates in support of this department. It was also complained that in revenue-producing undertakings there was only a balance of £37,000 to the good on a capital expenditure of over two million pounds.

LIGHTING AND GENERAL.

Buxton.—Tenders are to be obtained for pumps for the electricity station.

Limerick.—The Council have obtained sanction to borrow £60,000 for electric light.

Warrenpoint.—The Urban District Council have decided not to apply for an electric lighting order.

Brighton.—Sanction has been obtained to the borrowing of £550 for the purposes of the electricity undertaking.

Huddersfield.—The Town Council intend to apply for sanction to borrow £7,500 for supplying the township of Linthwaite with electrical energy.

British Insulated and Helsby Cables.—The directors have declared an interim dividend at the rate of 8 per cent. per annum on the ordinary shares.

Lowestoft.—An enquiry has been held into the Town Council's application for sanction to borrow £2,000 for laying of mains for private electric lighting.

Ossett.—The Town Council are negotiating for the purchase of Deanhead reservoir. Other expensive schemes are in view—viz., refuse destructor, electric light, and tramways.

Hull.—An enquiry has been held into the application of the Town Council for sanction to borrow £47,000 for the establishment of a telephonic system for the city and neighbourhood.

Grimsby.—The Great Central Railway Company has decided to illuminate the Grimsby fish pontoon by electricity. The company have their own generating station near the graving dock.

Londonderry.—The Corporation have decided to forward to the Lord-Lieutenant a protest against the action of the Board of Works refusing the Corporation a loan in connection with the private lighting scheme.

Quarry Bank (Staffordshire).—The Midland Electric Corporation have entered into a contract for the purchase at the Thorns, Quarry Bank, of a site for a power station for the supply of electricity in the district.

Norfolk.—The County Council have decided to apply for sanction to a loan of £500 for fitting up in the old asylum a system of fire-alarm bells, call points, telephones, tell-tale stations, ward bells, and bell pushers.

Electro Institute, Limited.—This Company has been registered with a capital of £6,000, the object being to carry on the business of medical electric specialists. Registered office: 26, Charles-street, Haymarket, W

Malton.—The Northern Counties Electricity Supply Company have decided to erect a generating station at Norton. The Malton Urban District Council object to the establishment of a station at Norton, as the original order specified Malton as the site.

Newcastle.—The Newcastle Guardians have received a report in favour of the entire relighting and heating of the union workhouse at a cost of £15,000, the scheme to include electric lighting and the heating of the house by hot water instead of steam.

Scarborough.—The Streets and Buildings Committee of the Corporation last Friday adopted a recommendation of the Streets Sub-Committee to ask the electric supply company if they would be prepared to light the streets from Falsgrave to Sandside with electricity and at what price. The lights, if erected, will be placed on the tramway poles.

Hove.—The Telephones Committee have approved the engineer's revised estimate of the cost of telephoning Hove underground; also application is to be made for sanction to borrow a sum of £4,691, instead of the sum of £3,000 previously applied for, to defray the cost of laying ducts and constructing other works in Hove for extending the telephone undertaking to that borough.

Recent Publications.—"Continuous-Current Dynamos and Motors, and their control," by W. R. Kelsey, B.Sc., A.I.E.E., 440 pp.; price 5s. net, post free; see advertisement. "Journal of the Institution of Electrical Engineers," edited by W. G. McMillan, secretary, part No. 163, price, 5s.; published by E. and F. N. Spon, Limited, 125, Strand. For contents see advertisement.

Injectors.—Messrs. Holden and Brooke, Limited, Sirius Works, West Gorton, Manchester, have just issued two new illustrated catalogues—viz.: List 37 (Section 1), injectors for boiler feeding by means of live steam—dealing with the firm's pattern S one-movement self-acting injector and other standard patterns. List 39 (Section 3) non-lifting injector—dealing with pattern C non-lifting injectors for feeding low-pressure boilers.

Barnstaple.—At the last Town Council meeting a statement was made with regard to the cost of electric light production per unit from Jan. 30 to June 24, and from June 24 to July 24. For the first-named period the cost was 2·9d. per unit, and for the second period 2·8d. per unit. The Council charges consumers 6d. per unit to provide for interest and redemption of capital, so that it seems the undertaking will prove a success.

British Thomson-Houston Company.—We are informed that this company has recently organised a new department, termed the "Local Companies Department," to handle its extensive business in connection with traction, lighting, and power schemes in various parts of the country, and has appointed as manager of this department Mr. A. W. Jones, who has been on the British Thomson-Houston Company's staff since its formation, and for the past three years has acted as assistant manager.

South Shields.—The balance-sheet of the past year's working of the electric lighting undertaking shows a considerable improvement on previous years in actual profits. After meeting all current expenses and payments in respect of capital and interest, there is a balance to the good of over £1,100. At the last meeting of the Electrical Committee it was decided to place £800 of this sum to the credit of the rates, £200 to reserve funds, while £160 will be carried forward. The reserve fund will thus be increased from £2,300 to £2,500.

Caversham.—A special meeting of the Urban District Council was held last week to consider a recommendation of the whole Council that a public meeting of the ratepayers be called to ascertain their opinion as to the advisability of applying to the Board of Trade in the coming session for a provisional order under the Electric Lighting Acts for a supply of electricity for Caversham. A motion was passed to the effect that the Council do not apply for a provisional order in the coming session, and that the public meeting of ratepayers be not called at present.

Accidents.—At Cardiff last week the underground electric lighting cables became ignited, and the fire was only got under after a portion of the cables had been severed, and consequently the electric light in the offices in the centre of the town went out when the current was temporarily cut off. On Friday, after the workmen had completed their day's work and left the premises, a steam pipe exploded in connection with a boiler at the Kensington Central electric lighting station, which is situated close to the West Brompton Station of the District Railway. Fortunately, no one was injured, and the damage caused was only slight.

Catalogue.—The Liverpool Electric Cable Company, Limited, Vauxhall-road, Liverpool, have just issued a new price-list of their manufactures including manufactures of vulcanised-rubber electric light and power cables, pure rubber-insulated cables, aerial cables, flexible cords, and dynamo wires. We are informed that the rubber used is manufactured on the firm's premises, and that Mr. Robert Taylor, who is in charge of the works, has had more than 25 years' experience in the manufacture of rubber and electric light cables. Mr. Taylor was with Messrs. W. T. Glover and Co., of Salford, Manchester, and their successors, when they were converted into a limited liability company, for a period of 11 years, seven of which he was works manager. Mr. Samuel Hartford, who is in charge of the commercial part of the business, was also with Messrs. Glover and Co. for 15 years.

Stock Exchange.—The Stock Exchange Committee has appointed Sept. 2 special settling day for County of London and Brush Provincial Electric Lighting Company's provisional certificates (fully and partly paid) for £250,000 4½ per cent. second debenture stock, and Sept 10 for British Westinghouse Electric and Manufacturing Company's further issue of 100,000 6 per cent. preference shares of £5 each fully paid, Nos. 375,001 to 475,000, and have ordered the above-mentioned securities and also Edmundson's Electricity Corporation's further issue of 20,000 ordinary shares of £5 each, fully paid, Nos. 50,001 to 70,000, to be quoted in the official list. Applications have been made to the Exchange Committee to appoint a special settling day in Marconi's Wireless Telegraph Company's further issue of 39,028 shares of £1 each fully paid, Nos. 157,084 to 196,111; and to allow the following securities to be quoted in the official list: Eastern Extension, Australasia, and China Telegraph Company's further issue of £282,400 4 per cent. mortgage debenture stock, and Eastern Telegraph Company's further issue of £302,169 4 per cent. mortgage debenture stock.

Aberdeen.—The Lighting Sub-Committee of the Town Council recently visited various parts of the town with a view to considering whether any improvements were required in the matter of street-lighting. They were much pleased with the new lighting arrangements alongside Westburn-road. Lamps, in which are used four different sets of burners, have been erected in Westburn-road and Burnside-road by way of experiment with a view to deciding which

Digitized by Google

type should be recommended for future use. The erection of a number of additional arc lamps has been authorised.

Clydebank.—The Town Council have agreed to issue a *plébiscite* paper to the electors on the question as to whether the burgh should or should not carry out its own electric light provisional order. Statistics are to be added showing what has been done by other burghs of similar size to Clydebank which has municipalised the electric light supply. According to Messrs. Kincaid, Waller, Manville, and Dawson's report, a capital expenditure of £34,310 for the whole or extended scheme will be required. The annual expenditure, including interest on sinking fund, would be £3,185, and the revenue from lights, refuse destroyed, and clinker sold at £3,433.

Huddersfield.—The borough electrical engineer's last report is as follows: Number of consumers: August, 1,806; July, 1,795; increase, 11. Lamps connected: August, 125,417; July, 124,462; increase, 955. Units metered: July, 1903, 100,754; corresponding period last year, 61,711; increase, 39,043, equals 63 per cent. The Bill confirming the Linthwaite electric lighting provisional order has received Royal assent, and the Council have approved the borough electrical engineer's plans and estimates for purposes of supplying electricity within the Linthwaite district, and will apply for sanction to borrow the sum of £7,500 for the purposes of carrying out the work.

Whitehaven.—A local paper says the Harbour Commissioners have power to levy 2d. a ton on vessels for lighting. The lighting of the harbour has lately cost from between £200 and £300 to somewhere about £400 for electricity. For the year ended Dec. 31, 1902, 74 vessels in the foreign trade, totalling 52,913 tons register, entered this port, and in the coastwise trade there were 1,341 vessels, totalling 155,210 tons register. The whole of this tonnage—208,123 tons—at 2d. a ton yields a revenue of £1,734. 7s. 2d. This statement suggests several ideas, but the only one that need be followed at present is that there is a very ample margin here between income and expenditure, and that at all events the harbour ought to be well lighted for the money.

Hornsey.—At the last meeting the Urban District Council considered a report from the special committee as to the supply of electricity dealting with a report of the consulting engineers, Messrs. R. Hammond and Son, on extensions necessary in the immediate future. They recommended "that the works covered by estimate No. 1 in the report be immediately proceeded with, that the mains and services included under estimate No. 3 be laid, and provided as circumstances may require, that the other works be undertaken when determined on by the Council, and that application be made to the Local Government Board for their sanction to the borrowing, as may be necessary, of the total sum of £61,050." In the end the recommendation reduced to £35,898 was agreed to.

Wigan.—In order to meet the increasing demand for electric current both for lighting and power purposes, the Corporation have erected at the Bradford-place station a new engine and generator of the latest type, which forms the largest set installed at the works up to the present time. The engine is one of 700 h.p., and was manufactured by Messrs. Willans and Robinson, of Rugby, whilst the generator was constructed at Messrs. Dick, Kerr, and Co.'s works at Preston. On Tuesday last week the new plant was set in motion by the Mayor (Councillor Richard Johnson, J.P.), who said that the selection of Mr. Slevin as borough electrical engineer had been entirely justified, and the appointment had in every way been a success. The condition of the works at the present time was in every sense eminently satisfactory, and was a credit to Mr. Slevin and the town.

London Gazette.—The partnership heretofore subsisting between Alfred Slatter and Richard George Goatcher, carrying on business as art metal workers and electrical engineers at No. 11, Buckingham-street, Strand, and No. 15A, Bellenden-road, Peckham, London, under the style or firm of Alfred Slatter and Goatcher, has been dissolved by mutual consent from Sept. 30, 1902. A petition for the winding up of the Electric Tramway Trusts, Limited, was presented to the High Court of Justice on Aug. 20, 1903, by William Bratby, of Alton Lodge, Hale, Bowden, Cheshire. The Electric Lighting and Fittings Corporation, Limited, Liverpool, is to be wound up voluntarily, and Mr. Simon Jude, chartered accountant, has been appointed liquidator. The first meeting in the estate of John Pierrepont Child, electrical engineer, of 150, Powis-street, Woolwich, and 109, Piedmont-road, Plumstead, Kent, will be held at 12 noon on Aug. 31, 1903.

Redditch.—The Urban District Council on Tuesday conferred with Mr. Monkhouse upon the electric light undertaking. The Council have decided that provision should be made in the proposed new loan for the new starting gear recommended and four sets of wattmeters. Upon the question of the provision of new gas-producing plant to enable the Council to use bituminous coal for gas production, instead of anthracite coal, Mr. Monkhouse strongly favoured the alteration of method. The cost of the alteration would not exceed £500. The cost of anthracite coal to the Council was 17s. 9d. per ton. The bituminous coal could be bought, delivered at Redditch, at 7s. 6d. per ton. Mr. Monkhouse repeated his belief that, under the new conditions, a considerable reduction in the cost of production would be secured. He repeated that it was not necessary to make any allowance for depreciation if the plant was maintained in good working order out of revenue. He also said there would be no need of any addition to the existing staff. He recommended that the sale of power for motor purposes at present prices (1d. to 2d. per unit) be continued, as in any case the plant had to be running continuously during the day under the alternating-current system.

Yarmouth.—The whole of the electrical lighting of the Hippodrome, inside and out, is carried out by plant on the premises, and to this end Mr. Gilbert has had laid down a 65-h.p. Crossley gas-engine, said to be the largest of its kind in the Eastern Counties, which will drive one of Crompton and Co.'s specially-constructed dynamos of 162 amperes at 220 volts with 210 revolutions per minute. This dynamo will supply current for the lighting of the whole of the arc lights in and outside the building, as well as the hundreds of small lamps distributed over the span of the roof. It is intended shortly to introduce four projector lights. Messrs. Crompton are also putting up one of their rotary transformers and a specially-arranged switchboard, which will enable the engineer at a moment's notice to disconnect the dynamo in case of temporary derangement or overheating, and receive the current from the borough tramway mains. The Crossley engine is fitted with a self-starter, and in this respect is unequalled in the district. In addition to working the dynamo, the engine will also be used to pump the water in and out of the sunk ring in the arena of the Hippodrome.

Wakefield Accounts.—The first annual report for the year ending March 31 last of the city electrical engineer (Mr. C. M. Shaw) contains the following figures: Expenditure—Generation of electricity, £1,626. 9s. 8d.; distribution, £27. 7s. 2d.; public lamps, £264. 12s. 3d.; management, £398. 1s. 9d.; special charges, £529. 17s. 5d.—total, £2,846. 8s. 3d. Income—Sale of current, £5,681. 7s. 3d.; rental of meters, £234. 7s. 2d.; public lighting, £719. 15s.; miscellaneous, £33. 19s. 6d.—total income, £6,669. 8s. 11d.; gross profit, £3,823. 0s. 8d.: interest and sinking fund, £2,874. 14s. 11d.; net profit (surplus), £948. 5s. 9d. Electricity sold, etc.—Units sold, private consumers, 393,315; public lighting, 96,140; used on works, 7,363; accounted for, 496,818; unaccounted for, transformer, mains, and leakages losses, 47,289; quantity generated, 544,107. Comparative output—Units sold year ending March, 1902, 331,183 (1903, 489,455); used on works, 7,549 (7,363); unaccounted for and used for testing, 37,159 (47,289); generated, 375,891 (544,107); maximum load demand in kilowatts, 310 (496). Load on station—March 31, 1903, 377 customers (312); 29,433 8-c.p. lamps (19,860)—total increase, 65 customers, 9,573 lamps. Number of motors connected, 17. Total horse-power, 190. Lamp connections—1901, 16,824; 1902, 19,860; 1903, 29,433. Total revenue, £6,669 (£5,195); total costs, £2,847 (£2,522); interest and sinking fund, £2,874 (£2,485); net profit, £948 (£187). If comparison be made it will be seen that the 1903 year shows an increased consumption of 158,272 Board of Trade units, being 47 per cent. increase over year 1902. Also that the total increase of lamp connections is 9,573, being 48 per cent. increase on 1902. The analysis of costs shows that all items of expenditure show a decrease. Works costs ·25d. per unit, total costs, ·40d. per unit on year 1902, which are most satisfactory. Works costs per unit sold—1903 ·80d. (1·05d.); total costs per unit sold, 1·25d. (1·65d.). The total length of high and low tension mains in the city at the end of March, 1903, was 14½ miles; March 31, 1902, 20,030 yards; extension during year ended March 31, 1903, 6,440 yards—total, 26,470 yards. In addition to new mains laid, 225 yards cable of various sizes has been overhauled and repaired and partly replaced.

Grimsby.—The annual report of the electrical engineer (Mr. W. A. Vignoles) shows that during the past year a considerable amount of work has been carried out in extending the plant and laying additional distributing mains. The department laid 1 mile 780 yards of distributing cable, and made 106 services to connect new consumers. Additional feeder cables, etc., and a sub-balancing station have become necessary, and the Council have recommended the expenditure of £7,000 for this purpose. With regard to public lighting, there are now 70 10-ampere and 10 6-ampere arc lamps in use. The consumption of current for power purposes has increased, and as a reduced charge is being made for this class of work, the demand will doubtless increase substantially in the near future. Considerable progress has been made with the undertaking during the 12 months. The number of lamps connected is not quite so large as anticipated, but Mr. Vignoles thinks that nothing has been lost by reducing the price, as the actual gross profit is larger than he estimated it would have been if the price had not been reduced. Lamp connections are still being made, and plenty of new enquiries are coming to hand, as shown by the fact that on March 31 there were 2,210 8-c.p. lamps applied for and not connected. The total number of lamps applied for and connected is 23,544. The total cost of production works out at 1·4d. per unit, which compares favourably with that obtaining in other towns. During the year the gross profit amounted to £3,277, or 5⅝ per cent. on the average capital expended during the year. Interest amounts to £2,873, the sinking fund is £1,826, so that the total capital charges amount to £4,699, equal to 7·29 per cent. on the average capital expended, and a net deficit of £1,422 is the result, as compared with £2,015 last year. The total cost of supplying the current to the tramways company amounted to 1d. per unit; the average price obtained being 1½d. per unit, the gross profit on the supply of current to the tramways company was £819. The cost of the plant installed for traction work, including a share of the buildings and spare plant, is about £9,650; the interest and sinking fund last year on this amount was £705, so that during this period a net profit of £114 was made. If interest and sinking fund had been obtained at 6 per cent. a profit of £219 would have been made. The engineer considers that these figures prove conclusively that the price at which the committee are selling current to the tramways company leaves a safe margin of profit. The estimate for next year's working is as follows: number of lamps connected, March 31, 1904, 29,500; gross profit, £4,514; interest and sinking fund, £4,940; net deficit, £426. The matter of automatic stokers has been referred back again to the committee, as the engineer desired some further information. The monthly report of the engineer shows an increase in the number of lamps connected of 1,034 over last year. There has been an increase of 7,000 units in the current consumed by the tramway company during the past month as compared with the corresponding month last year, and an increase of 3,500 units over the amount consumed during the previous month. The engineer expresses disappointment that the destructor had not supplied

Digitized by Google

more steam, and there was practically no spare steam from the destructor after supplying the forced draught required and the steam required for the clinker crusher.

Dublin.—A special meeting of the Municipal Council was to be held last night for the purpose of considering a report of the Lighting Committee on the extra expenditure in connection with the new electric lighting system, to cover which the committee recommend that an application for a loan should be made to the Local Government Board. The report states, according to the *Dublin Evening Express*, that "the Lighting Committee have from time to time laid before the Council various reports on additions to the electricity scheme, and have now pleasure in submitting a report from Mr. Robert Hammond, setting out in detail the various items of the extra expenditure incurred in connection with the complete system. The total amount is £48,000 in respect of the city undertaking, in addition to a sum of £5,961 expended in the city on the Clontarf electric lighting scheme, regarding which your committee submit a separate report. In every case in which it was possible full particulars of the additions to the scheme were submitted to Council before the expenditure was entered upon, but, of course, many difficulties arose from time to time which had to be dealt with at once in connection with building work and the laying of street mains. In the case of the latter work especially, very serious difficulties were met with, owing to the extraordinary number of old cellars run out under many of the streets, and your committee had to carry out from day to day arrangements with owners of city property to enable the work to be proceeded with. They are pleased to be able to report, however, that although these difficulties added to the cost of laying the mains, in not a single case did the arrangements effected entail the payment of compensation, the owners and tenants of property everywhere showing a disposition to assist your committee in every way reasonable." An exhaustive report from Mr. Hammond is also to be submitted to the Corporation. It is dated July 28, and the following are extracts from the document: "The capital expenditure sanctioned by the Local Government Board was £254,500. The contracts given out in respect of the plant, etc., embraced in the original scheme, covered by the Local Government Board's sanction of £254,500, showed a saving of £4,529. In carrying out the work, however, its scope has been somewhat enlarged with the authority of the Council from time to time, with the result that liabilities beyond the £254,500 have been incurred up to about £302,500, leaving an amount of £48,000 not yet sanctioned by the Local Government Board. I may here point out that in addition to the above there is a sum of £5,961, which sum represents the value of certain works executed in order that the Council may be in a position to meet its obligations with regard to giving a supply of electricity to Clontarf next year." The items making up these total figures are then set out, and they include iron troughing for the mains, substituted for earthenware troughing included in the scheme, £6,000; extension of engine-house to provide space for additional plant and Lancashire boiler, £4,261; substitution of Lancashire boiler for water-tube (extra seatings), £500; coal store and provision for mechanical coaling and ash disposal, £5,920; less provision in original estimate, £1,600—£4,320; lowering gear for arc lamps, £1,400; culvert at Victoria Bridge, £2,700. No provision, Mr. Hammond states, was made for this, as the consulting engineer understood that cables would be taken through culvert to be constructed in connection with the main drainage. Storing plant in consequence of delay in starting work in Pigeon House, £781; expenditure at Pigeon House on extra well, pipes, foundations, etc., £1,250; extra cost of constructing Sackville-street sub-station underground, £446; extra sub-station at Trinity College, £575; Trinity College transformers, £514. 16s.; removal of Thomas-street sub-station, £352; additional mains in present area, £2,370; sundries, including new design of brackets for arc lamp-posts in present area, for which price is under discussion with the contractors, say £500; demand indicators, £2,000; small meters, £500; expenditure in Dublin on preliminary expenses, legal expenses, contract charges, stamps, printing, clerk of works, water supply, etc., £3,000. The amount of contracts entered into in connection with the undertaking is as follows: total of contracts entered into up to Feb. 7, 1903, £250,366. Until complete measurements are made and agree with the contractors it is not possible, says Mr. Hammond, "to deal with the exact figures, but subject to this proviso, I beg to submit the following statements: estimated cost of additions to building work at Pigeon House, including provision for Clontarf lighting already reported to Council, £5,106; additions to building work at Pigeon House, not yet reported to Council, £1,259. 0s. 3d.; additional sub-stations and of additional work in connection with those contracted for originally, £2,139. 14s.; additional mains and additional work, including provision for Clontarf, £10,602. 17s. 9d.; increasing the section of mains in certain streets, and alterations to cellars, etc., £10,331; sundry extras on contracts not included in the remaining lists, £3,534. 8s.; total contracts entered into and reported on on Feb. 7, 1903, £250,336. The extra expenditure to be allocated as follows: to city lighting, £48,000; to Clontarf lighting, £5,961." The Lighting Committee say they have very carefully considered the items of Mr. Hammond's statement, and recommend them for the approval of Council, and recommend, further, that application be made to the Local Government Board for its sanction to a supplemental loan of £48,000, to cover the extra expenditure on the electricity scheme as set out in the above statement. The following report of Mr. Hammond on the proposed electric lighting of Clontarf is appended. It is divided into two sections—viz., private lighting and public lighting—and is as follows: "Under the Dublin Corporation Act (1900) you have taken over the obligations of the Clontarf Electric Lighting Order (1889) with the exception that the date by which the supply of electricity has to be given in the compulsory area is extended to Aug. 6, 1904. Under the Clontarf order the compulsory area is made up of the following streets: Annesley Bridge-road and Strand-road, known as the High-road, skirting the seashore (from the township boundary at Annesley Bridge to a point in the said High-road, immediately opposite the centre of the carriage gateway leading from said High-road to the mansion of St. Anne's, which point is distant 168 yards or thereabouts, measured in an easterly direction from the intersection of Blackbush-lane with the High-road aforesaid); Fairview-strand and Fairview (from Phillipsburgh-avenue to the High-road as aforesaid); Phillipsburgh-avenue (from Fairview-strand to the intersection of Annadale-avenue with Phillipsburgh-avenue aforesaid); St. Lawrence-road, Castle-avenue (from the High-road aforesaid to the intersection of Church-road with Castle-avenue aforesaid); Strandville-avenue, St. Joseph's-terrace, Marino-avenue, Beechfield-avenue, and Mooney's-lane, and it is in these streets that the distributing mains must be laid by the date referred to above—viz., Aug. 6, 1904. Keeping these observations in view, we have already laid two 5,000-volt feeder mains and one telephone cable from Fleet-street to Newcomen Bridge, and the next step will be to extend these mains into Clontarf. In the ordinary course, I should propose to deal with the lighting of Clontarf in exactly the same system as Dublin—that is to say, by a number of transformer sub-stations distributed over the whole area. It does not, however, appear to me that the demand in Clontarf would, at any rate for the present, justify you in going to the expense of a number of sub-stations, and I therefore propose to limit the number to one, and to deal with the balance of the load by means of single transformers, fixed either in pits below ground or in pillars above ground—preferably the latter. These transformer pits or pillars could, of course, be replaced by regular sub-stations at a later date should the demand warrant it. It would be possible from an electrical point of view to supply all the transformer pits direct from the 5,000-volt mains, but I should hesitate to use such a high pressure as 5,000 volts for such a purpose, and I therefore recommend, in that case, that the pressure be reduced at the sub-station at Clontarf to not more than 2,000 volts—in other words, the distribution of energy in Clontarf would be on somewhat similar lines to the distribution in the old area, Dublin, except that three-phase mains would be laid where practicable in place of simple concentric mains. The work to carry out the above scheme would be as follows: (1) the extension of two extra high-tension feeder mains from Newcomen Bridge to a sub-station at Clontarf; (2) the extension of the telephone cable from Newcomen Bridge to the above sub-station; (3) the building and equipment of an extra high-tension sub station; (4) the high-tension main from the sub-station, with branches to transformer pits, as required; (5) seven transformer pits, or pillars; (6) the necessary low-tension distributing mains. The above would be sufficient to deal with the compulsory area as scheduled in the Clontarf order, and I estimate that the cost of carrying out the work would amount to £14,000. In addition to the streets comprised in the compulsory area, there are several streets in which new houses have recently been built, from which a profitable load might be expected. Amongst those streets I am inclined to include the following: Haddon-road, Vernon-avenue, Howth-road, Hollybrook-road, Hollybrook-park, Seafield-avenue. The estimating cost of distributing mains in these streets would be £1,250. I also add £1,550 to provide for house services, meters, etc. I have prepared an estimate of the cost of lighting the sea-front as far as Dollymount with arc lamps, including the extension along North Strand, necessary to meet the Dublin lighting, which at the present moment will stop at Newcomen Bridge. For this purpose about 56 lamps will be required, placed something like 100 yards apart. It would not be practical to give energy to these lamps from the motor-generators at Fleet-street, and I should, therefore, propose that these lamps be of the alternating-current pattern, controlled from the sub-station. I draw your attention to the fact that you have power under the Dublin United Tramways Electrical Power Act (1897) to utilise the poles of the tramway company for the purpose of public lighting. Clause 15 of this Act runs as follows: 'Provided, however, the road authority may for the purposes of their own street-lighting utilise any of the pillars or standards at their own cost, and all the pillars or standards, whether erected in the road or footpath, shall be so constructed that they can be utilised for the purpose of street-lighting, and by the road authority, whenever they require to do so, free of charge.' The objection to the use of the tramway posts is that they are not situated throughout the area in the positions most suitable, at street corners, etc., for public lighting, nor can lowering gear be applied to them. I, therefore, submit two estimates, the first for the utilisation of the tramway poles, and the second for the erection of similar posts to those in the city, the alternative estimates being as follows: (1) for the utilisation of the tramway poles, £4,750; (2) for separate posts, with lowering gear similar to those in the city, £5,239. The cost of carrying out the whole scheme outlined above would be as follows: compulsory area, £14,000; other prominent streets. £1,250; house connections and meters, £1,550; public lighting from Newcomen Bridge, Dollymount, say, £5,239; already expended, £5,961—total, £28,000." The Lighting Committee believe that the members of the Council will agree that as the Corporation is bound to carry out the private lighting scheme for the compulsory area, it is advisable that it should be made complete by including the extra roads specified in Mr. Hammond's report, and the public arc lighting of at least the sea road, as suggested by Mr. Hammond. In the case of these extra roads, however, the committee suggest that the laying of the distributing mains be made conditional upon a reasonable number of promises to use the current being secured from residents. The committee consider that the suggestion of separate posts for the public arc lighting should be adopted, as apart from the advantage of better positions, the annual saving effected by the lowering gear would more than compensate for the slight extra capital cost. The Lighting Committee accordingly recommend that application be made to the Local Government Board to authorise the raising of a loan of £28,000 for the carrying out of the work above specified.

PROVISIONAL PATENTS, 1903.

AUGUST 17.

17734. An electrical magnetic automatic stop-action appliance to be used with fustian, cerduroy, velvet cutting and other machines. Robert Reynolds, 101, Oxford-road, Chorlton-on-Medlock, Manchester.

17744. Improvements in and relating to the shifting of points and plough guides on electric tramways. William James Stewart, 96, Buchanan-street, Glasgow.

17745. An improved automatic safety device for use in connection with overhead electric conductors. Arthur Morris, 6, Finkle-street, Stockton-on-Tees.

17767. Improvements connected with the electrical propulsion of vehicles on the overhead system. Charles Shields McIntire, 40, Chancery-lane, London.

17814. Improvements in safety collision devices for electric tramcars. Reginald Haddan, 18, Buckingham-street, Strand, London. (Ramon Rué y Montparlé, Spain.) (Complete specification.)

AUG. 18.

17851. Improvements in or relating to electric railways. George Westinghouse, Westinghouse Building, Norfolk-street, Strand, London.

17871. Improvements in or relating to electric arc lamps known as flame arc lamps. Charles Oliver, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

17886. Improvements in lifeguards for electric cars and other self-propelled vehicles. Arthur Royle, 6, Lord-street, Liverpool.

AUG. 19.

17940. An improved method of calibrating alternating-current instruments and means for use therein. Charles George Lamb, 77, Glerson-road, Cambridge.

17974. Improvements connected with electric lamp fittings. Robert Walter Braham, 173, Fleet-street, London.

AUG. 20.

17994. A device for clamping a broken trolley arm or pole on an electric tramcar. James Dawes, 26, Buxton-street, Manningham, Bradford.

18010. Improvements in galvanic batteries. Lothar Fiedler and Frederick Julius Gerard, 22, Southampton-buildings, Chancery-lane, London.

18036. Improvements in or connected with arc lamps. William James Davy, 40, Chancery-lane, London.

AUG. 21.

18077. Improvements in electric trolleys. Jean Lauvernier, 23, Mittelstr., Berlin, Germany.

18080. Improvements in or connected with means for preventing corrosion and injury to water-mains by electric currents received through the rails of tramlines. William Bradshaw Leachman, 33, Chancery-lane, London.

18120. Improvements connected with electric lamps. Robert Walter Braham, 173, Fleet-street, London.

18121. Improvements connected with enclosed or open electric arc lamps. Louis Carl Henry Mensing, 173, Fleet-street, London.

AUG. 22.

18142. Improvements in or relating to the receiver cradles of telephone instruments. Robert Frederick Hall and the Electric and Ordnance Accessories Company, Limited, 24, Temple-row, Birmingham.

18143. Improvements in or relating to telephone apparatus. Robert Frederick Hall and the Electric and Ordnance Accessories Company, Limited, 24, Temple-row, Birmingham.

18177. Improvements in electric arc lamps. William Winterborne Smith, 36, Chancery-lane, London.

18185. An improved electrically-controlled indicator. Siemens Bros. and Co., Limited, and George Sylvester Grimston, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

18186. Improvements relating to telphers. Siemens Bros. and Co., Limited, and Arthur Stebbins Clift, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

18197. Improvements relating to electric apparatus for motorcars. Arthur Trevor Dawson, 45, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published September 10, 1903.

1902.

18855. Electrically-operated switches or circuit breakers. Hewlett and Button. (Date applied for under International Convention, Jan. 7, 1902.)

18999. Electric current regulators. British Thomson-Houston Company, Limited. (Wood.)

18230. Devices for making and breaking electric circuits. Lake. (General Electric Company.)

18706. Alternating-current electricity meters. De Ferranti and Hamilton.

18924. Variable speed-driving mechanism for electric meters. Lake. (General Electric Company).

20438. Electric car pulleys. Knowles.

20871. Electric storage batteries and the like. Sutherland and Marcuson.

21213. Method of and means for lighting miners' and other lamps by electricity. Patterson and Darrah.

22760. Tramway and railway rails, and means of bonding such rails for the purpose of electrical connection. Bigwood.

23426. Electric accumulators. Garcin.

26999. Electromotors and similar electrical apparatus. Macfarlane.

1903.

5278. Hood for telephones. Mirow and Hepke.

12516. Electromagnetic machine for the ignition of the mixture in explosion motors. Pichard.

13707. Mechanism for mounting and driving dynamos on railway trucks. Kennedy.

15479. Regulating systems of electric distribution. Justice. (National Battery Company.)

15489. Regulating systems of electric distribution. Justice. (National Battery Company.)

15552. Apparatus or devices for transmitting and receiving messages by wireless telegraphy. Burke.

15569. Method of and apparatus for wireless signalling, chiefly designed for determining the nautical bearing of navigable vessels. Ladd.

NOTES.

Book Received.—"Practical Construction of Electric Tramways," by Mr. Wm. R. Bowker, C.E. The information given in this, the first edition, is limited to the laying out and construction of the permanent way and the overhead equipment of electric tramways. In future editions closer attention will be paid to the slotted conduit system, and also to electric street, underground, and elevated railway systems. The book is published by Messrs. E. and F. N. Spon, Limited, at 6s.

Institution of Civil Engineers.—The secretary of the above institution has issued another batch of papers, comprising vol. cliii. of the society's proceedings. Among those which interest us more particularly are "Electric Automobiles," by Mr. H. F. Joel, with an abstract of the discussion; "Cauvery Power Transmission Scheme," by Mr. H. T. Hincks; "Construction of the Permanent Way of Electric Tramways," by Mr. Robert Bruce; and "Municipal Work in Sydney, N.S.W.," by Mr. R. W. Richards.

Electric Traction Trials.—Advices from Berlin state that trials are being conducted on the Prussian State Railway at Spindlersfelde with a new system of electric traction, employing single-phase alternating currents. The motor used is a special contrivance of the Union Elektricitäts-Gesellschaft. The one great claim which is put forward in favour of this motor is that it is capable of giving every desirable degree of speed, and notwithstanding is exceedingly simple in construction. So far the trials are reported to have given the utmost satisfaction. They are now being continued, and no doubt some authoritative data of the results will be issued before long.

Literary Notice.—Messrs. Longmans, Green, and Co. announce that they will publish during the present month a new edition of "The Steam-Turbine," by Robert M. Neilson. The size of the volume has been nearly doubled. Large additions have been made to the chapters descriptive of the Parsons and De Laval turbines, the additions including dimensions drawings. Illustrated descriptions are now given of the Westinghouse-Parsons, Curtis, Stumpf, Seger, and Schulz steam-turbines. Indicator diagrams are shown taken from the latter turbine by Herr Schulz's ingenious device. The new Rateau governing device is also described. The chapter on "Marine Propulsion" has been greatly extended, and the recently completed turbine vessels are now included.

Electricity in Sicily.—The use of electrical machinery in the sulphur mines of Sicily is increasing. We learn from a British consular report that at the Trabonella mine, which is about the largest in the island, the proprietors have erected four 120-h.p. gas-engines of German manufacture with the relative Dowson gas plant, using anthracite coal, four dynamos of 110 h.p., which produce the necessary power for electric winding, electric haulage on surface, electric pumps of 10 h.p. each, electric lighting on surface and underground, and for a 25-h.p. flok and maccaroni mill, which supplies the workpeople with food, at lower prices than those current in the neighbouring towns. Developments are impending, and manufacturers will find an open field for their wares in the island of Sicily.

Wireless Telegraph Conference.—The result of the international conference held recently on the initiation of Germany to consider the subject of wireless telegraphy was announced in Berlin on Wednesday night. The chief recommendation arrived at by the conference, it is reported, is that there should be an international convention making it compulsory for all coast stations in all countries to accept and transmit wireless messages, whether by the Marconi or other systems. This was agreed to by a majority of six out of the eight countries represented, Great Britain and Italy being in the minority. It is stated that the above recommendation was directed against the Marconi Company's attempt to create a monopoly. The conference also recommended that tolls should be fixed, as for ordinary telegrams, by international arrangement.

Pupin's Long-Distance Telephony.—Dr. Jeutsch, who is attached to the German telegraph service, has been criticising Dr. Pupin's system of long-distance telephony. His objections are levelled, not at the electrical features of the system, but simply at certain mechanical difficulties that might be encountered. In his opinion external pressure of the water would increase with the depth to which a submarine cable was laid. At a depth of two or three miles it would not be impossible that a pressure of 3,000lb. to the square inch would be found. From this, according to the *Scientific American*, Dr. Jeutsch concludes that Pupin's inductance coils, unless constructed with extraordinary strength, would be crushed in. Dr. Jeutsch, however, as well as Prof. Pupin himself, agrees that the difficulty is by no means insurmountable.

Atlantic Wireless Telegraphy.—Mr. Marconi now promises to establish a commercial service of wireless telegraphy across the Atlantic within three months. We conclude from this that the new installation in Cornwall, which was stated to be essential for the dispatch of wireless messages to the other side, will be completed by that time. However, Mr. Marconi, who arrived in New York on Sunday, told a Dalziel correspondent that he would then be prepared to send messages of any length by wireless telegraphy from Canada to England. He is also reported to have said that the "Lucania" had been in touch with land during the whole of her voyage across the Atlantic. Mr. Marconi evidently recognises the impracticability of a commercial service so long as it can be interfered with by other wireless telegraph systems. He is going to take legal advice on the point.

Water Power in New Zealand.—In the last few years great attention has been paid by some of the principal municipalities in New Zealand to the possibilities of water power for electrical purposes. There are several swift-flowing rivers in the colony which offer good opportunities for this, not the least important of which is the Waitaki River. An early visit from an American electrical expert employed by the Government is expected to test the resources of this river, with a view to a scheme for supplying three boroughs with electricity and power. These are the cities of Timaru, Waimate, and Oamaru, and the proposal to work in conjunction in this matter gives better hope of the scheme being eventually carried out than if it were undertaken individually. The Waitaki River has already been subjected to a preliminary inspection by a Government local inspector, whose reports have decided the Government to seek the more practical advice of an American expert on the question.

Becquerel Rays and Water.—Some interesting facts about an action of radium rays on water were brought into prominence in a note by F. Kohlrausch, recently read before the German Physical Society, Berlin. A mixture of radium and barium bromides was placed in a flat capsule and covered with an aluminium sheet 0·1mm. in thickness, and the rays emanating from it allowed to traverse a water layer about 18mm. in thickness, when an acceleration in the increase of the conductivity of the water was noted during a prolonged action of the rays, though no immediate effects were stated. The author is unable to

Digitized by Google

give a sure interpretation of this fact, as the radium rays may either have given rise to a development of ions within the water or else have accelerated the disaggregation of the walls of the glass tube. As regards a third hypothesis, according to which something like bromine would have penetrated into the tube, the author states that this is highly improbable, a special experiment having given negative results.

American Electrochemical Society.—We have received from Philadelphia an announcement of the fourth general meeting of the above society to be held at Niagara Falls on the 17th, 18th, and 19th of this month. In the choice of Niagara Falls as the place of meeting the society has, no doubt intentionally, lighted on the centre of electrochemical activity in the States, and a good part of the time will be devoted to visits to power-houses and certain of the electrochemical plants which are open to inspection. A large number of papers will be read and discussed at the three days' meeting, and some of the leading American electrochemists will participate. We are glad to note that an arrangement has practically been arrived at between this society and the recently formed Faraday Society for a free exchange of their respective *Transactions*. This is as it should be, and although involving extra expense on both sides, the advantage to the members of the societies of receiving these volumes regularly is ample compensation for any pecuniary loss.

Automobile Reliability Trials.—The Trials Organisation Committee of the Automobile Club have now made public the list of entries for their fifth annual reliability trials. An analysis shows a gratifying increase in the British competitors as compared with last year. There is a total of 76 British cars, compared with 41 in 1902; the increase for foreign cars being from 43 to only 59. Thus it will be seen that the British increase is 85 per cent., while that of the foreign entries is only 37 per cent. There is a net increase of 16 in the number of British firms in the list of competitors, which is in itself a strong argument against unduly strict administration of the law. The principal increase is in cars built to meet the requirements of people of moderate incomes, say cars costing under £400, the annual upkeep of which should certainly not exceed £50 per annum, and of this type upwards of 50 cars are entered for the trials. Out of a total of 140 entries, only 10 are steam cars, which shows the enormous preponderance of the internal-combustion engine in popular favour.

Electrical Exports from the States.—These show an increase for the fiscal year ended June 30 last, although the exports for the previous 12 months were less than those in 1901. The figures as given in the annual statement of the U.S. Treasury Department are interesting. Last year the value of the electrical machinery exported from the States was £1,155,891, of electrical appliances, including telegraph and telephone instruments, £841,324, making a total value of £1,997,214. In 1902 the exports were valued at £1,802,301, an increase last year of £194,913, or about 10¾ per cent. But, as before stated, there was a diminution in the exports for 1902 as compared with 1901. A further comparison of the figures shows that the gain last year was in both electrical machinery and appliances. As in previous years, Great Britain and the British Colonies were America's best customers for electrical machinery, the exports to Great Britain alone amounting to £451,212, or nearly double those to British North America, which comes next with a total of £248,180. Mexico is third on the list with a total of £117,652, and British Australasia fourth with £85,685.

Electric Lighting in Buenos Ayres.—A monopoly of electric lighting at Buenos Ayres is held by a German company, but originally the undertaking was in the hands of a syndicate of French capitalists. In 1901, however, the German Transmarine Electricity Company purchased the undertaking from the French company, and this was followed by the acquisition of the works of the River Plate Electricity Company in that city, and more recently by a decision to obtain possession of the electrical works of the Primitiva Gas and Electric Lighting Company of Buenos Ayres. The latter works have been leased to the German company for a period of 41 years on the payment of £30,000 per annum, but on completion of that period the works will pass into the possession of the German company without further payment. Thus we have a case of German private enterprise absorbing both English and French interests in a particular business in one town, and creating a monopoly which practically controls the whole of the electrical lighting works in Buenos Ayres, and also owns the metropolitan tramway in that city.

Aluminium Production.—At present Niagara Falls is the centre of the aluminium industry in the United States, and the Pittsburg Reduction Company is the sole producer of the metal in that country. However, this company is preparing a power plant at Massena, New York, which is expected to double the output of aluminium in the States. The new plant will consist of four units of 300 h.p. each, generating current at 1,500 volts. The approximate output of aluminium in the States during 1902 was 7,300,000lb., as compared with 7,150,000lb. in the previous year. Twenty years ago the annual output was 83lb., and three years later it had risen to 3,000lb. Each year for the next 10 years the industry made steady advances, until in 1896 the output was about 1,300,000lb., increasing year by year until now the output has reached over 7¼ million pounds, which looks like being doubled before very long. Aluminium has advanced in popularity for use on transmission lines very considerably in the last few years, but it has also attained a high standing for the manufacture of domestic and culinary articles. The price is believed to be regulated by an international agreement between the producers.

Guttapercha in the Philippines.—The belief that the Philippine Islands could furnish a very valuable supply of guttapercha if properly cultivated, is confirmed by a report which has recently been issued by Dr. Penoyer L. Sherman, jun., of the Philippine Forestry Bureau. The report has been made as the result of an expedition in search of guttapercha trees in the Philippines, during which several species of the trees were found in the island of Mindanao, and the islands of the Sula Archipelago; and it is stated that the Chinese have built up a large trade in this product. The total exports of guttapercha from the Philippines last year is put at 14,000lb., but the report states that particularly in the mountainous regions the guttapercha tree is to be found in abundance. Dr. Sherman extracted the gum from some of the trees during the expedition. One tree, 160ft. in height and 8ft. in circumference, yielded 9½lb. of dry guttapercha. Under cultivation it would probably have yielded 20lb., while, had the bark and leaves been secured, from 150lb. to 200lb. could have been obtained. In view of the present wasteful methods of harvesting now in use by guttapercha planters it is proposed that the United States Government shall take over the business of rubber cultivation in the Philippines, with the object of regulating the supply and preventing much of the cheating which is now done by the Chinese merchants.

Electricity in the East.—It is not to Northern China that one would usually look for an example of electrical progress, but there is at least one place on the eastern shore of the Liaotung Peninsula which might well set an example to many of the Western towns. We refer to the city of Dalny, which lies near Port Arthur in that portion of the Chinese Empire which was leased to Russia in 1898. Electrically, Dalny is up-to-date. It has both telephones and the electric light. The central station, which is considered the finest electric plant in Asia east of Singapore, was finished over a year ago. It is equipped with three of Ganz and Co.'s generators, with a total of 1,000 h.p., and has a reserve space for additional machines to double its present capacity when required. Dalny, besides other things, is an important seaport, and has a dry dock 380ft. long, 50ft. wide, and 18ft. deep, which is equipped throughout with electric pumps. A larger dry dock is building, at which electricity will also be adopted. In connection with the dry dock are the harbour repair shops, with foundry, smithy, machine and fitting shop, boiler shop, etc. All these shops are electrically driven and lighted throughout. Dalny also boasts an excellent telephone service, and altogether it may fairly claim to be one of the most progressive cities in the East.

Large Electric Locomotives.—In the issue of the *Street Railway Journal* for Aug. 22 an interesting description is given of two large electric locomotives which have been constructed for the Baltimore and Ohio Railway for tunnel work. Each locomotive is made up of two 75-ton units, so that its total weight is 150 tons. It will be operated with type M control of the General Electric Company, the control being so arranged that each section may be operated independently, or any number of sections coupled together and operated from any one section. The locomotive is designed to draw a 1,600-ton train on the Baltimore and Ohio trunk line through the tunnel over an 0·8 of the 1 per cent. grade at a speed of 10 miles an hour, and over a 1½ per cent. grade at a speed of nine miles per hour on 625 volts. Under practical operating conditions the motors have sufficient capacity to maintain this service hourly, running loaded up the grade and returning light. In starting, the motors have more than sufficient capacity to handle as heavy a train as the weight on the drivers will permit. The motor equipment of each unit consists of four G.E. 65 motors of about 225 h.p. each, with special slow-speed winding, making a total for the eight motors of 1,800 h.p. The locomotives have recently been finished at the General Electric works, and will be put in service almost immediately.

Superheating Tests.—We have received for publication results of some experiments recently carried out at Messrs. Mechan and Sons' works at Glasgow by Prof. Watkinson to determine the percentage gain in power, with a given boiler, due to the application of a superheater, and the saving in steam and coal for a given output in horse-power. A Lancashire boiler, 8ft. diameter and 30ft. long, was used, and the superheater was one of Watkinson's shunt-circuit type. The test with saturated steam was of the same duration as that with superheated steam, about seven hours, and among the results obtained are the following: The average temperature of the steam leaving the superheater was 492·5deg. F., and at the engines 470deg. F. The electrical horse-power during test averaged 176·2 in the case of saturated steam, and 240·8 in the case of superheater; the gain in power due to superheating was thus 36·6 per cent. The consumption of steam per electrical horse-power hour comes out, however, at a very high figure, even with superheated steam. In the test with saturated steam it was 44·9lb., and with superheated steam 31·7lb. The consumption of coal per electrical horse-power hour was 7·51lb. and 5·45lb. respectively. The main result, however, is that by superheating a saving was effected in steam of 29·3 per cent., and in coal of 27·4 per cent. The actual amount of coal burned on each trial was practically the same.

Technical Instruction for Apprentices.—At the present time the large railway companies are particularly anxious to encourage the technical education of the most promising of the apprentices in their workshops. We know of one or two cases in which the apprentices have been granted several months' leave of absence in order to take up technical study—of course, under the surveillance of their employers. The Great Western Railway Company is now offering facilities, in conjunction with the Swindon Education Committee, for a limited number of selected students to attend day science classes at the technical school. Candidates must be registered apprentices between 17 and 18 years of age, and must have spent at least one year in the works. Another stipulation is that they must have regularly attended for at least one session in the preparatory group of evening classes at the technical school. The number of studentships will be limited to 30 at any one time in groups for a three years' course. The Great Western Railway Company deserves all praise for its generosity in this matter. Not only will the company pay the students their wages as if at work in the factory, but also their school fees. The students attending the day classes will be expected to give some time each evening to private study. Those who distinguish themselves will be allowed to spend part of their last year in the drawing office and chemical laboratory.

Institution of Electrical Engineers.—From the secretary of the above institution we have received three volumes—viz., Part 5, No. 163, of the *Journal*, index to vol. xxxii., and a new list of officers and members, corrected to June 30 this year. The first-named volume contains the following papers with the discussions thereon: "Applications of Electricity in Engineering and Shipbuilding Works," by Mr. A. D. Williamson; "Electric Driving in Machine Shops," by Mr. A. B. Chatwood; "Electricity Supply for Small Towns and Villages" (Leeds Section), by Mr. A. B. Mountain; "On the Preservation and Packing of Plant for and in Bengal" (Calcutta Section), by Prof. Bruhl; "The Carriage of Goods on Electric Tramways" (Manchester Section), by Mr. A. H. Gibbings; "Notes on Motor-Starting Switches," by Mr. A. H. Bate; together with a paper by Messrs. C. D. Taite and R. S. Downe, entitled "Comparison Between Steam and Electrically Driven Auxiliary Plant in Central Stations" (Manchester Section), and an original communication by Mr. F. W. Carter, M.A., entitled "Some Notes on Heat Runs.' This number also contains the annual report of the Council for the past session, and is the last of vol. xxxii. As usual, there will be no further issue until the end of the year. The membership of the Institution, including associate members, associates, students, and foreign members, as shown by the new list, now stands at the highly respectable figure of 4,818.

Steam and Electric Competition.—In America the railway companies operating their lines by steam have recognised by this time that they must adopt some radical changes if they are to stem the inroads on their revenue, resulting from the competition of the electric roads. They must prepare to meet this competition, and various proposals have been made for achieving this end. The heavy expense involved in completely changing over from steam to electric traction, has induced several of the large

Digitized by Google

railways in this country to adopt motorcars which are self-contained and driven by petrol motors. In America they have another idea. It is to construct electric lines alongside the present tracks, so that they may operate an electric service in those districts mostly affected by the electric tramway, or street railway, competition, and at the same time maintain their steam trains for long-distance traffic. This, it is thought, would solve the question as to local traffic, which is what the steam railways are rapidly losing. The competition of the electric lines is, of course, far more active in America than in this country, but English railways may profit by the experience of their American cousins, and take up the question before it is too late. It will be apparent that the electric lines, if constructed on private ground, such, for instance, as is proposed by the American railways, would prove more advantageous than if laid in the form of tramways on the public roads, in which case they would not be able to reach the high speeds required owing to other traffic.

Tramways and Light Railways Association.—There are two or three announcements of much interest in the official circular issued by the above association for the present month. In the first place, we note that the council has decided to grant annually a prize of a bronze medal and books to the best essay on improved means of communication. Papers, which must be sent in to the secretary on or before Nov. 30, must not exceed 4,000 words in length. There will probably be plenty of competitors for the prize, and some interesting papers should be the result. Another announcement of importance is that the next tramway congress will be held early in September, 1904, in Vienna. The International Tramways and Light Railways Union has prepared a list of the questions to be submitted and discussed, to which replies are requested before Oct. 30 next at the latest. The subjects are briefly: depreciation, transfers, savings in current consumption, brakes, guard wires, trailers, electric traction on light railways, fall in potential thereon, permanent way therefor, comparative legislation, accounts and reports, general inspection, use of automotors on light railways. The first meeting of the winter session of the association will be held in London at the beginning of October, when Mr. R. H. Scotter will deliver an address on "Fiscal Policy as affecting Tramway and Light Railway Enterprise." Notice of time and place of meeting will be made soon. Another matter of interest is a proposal to form a tramway club in London if the scheme meet with sufficient support.

Experiments with "N" Rays.—Mr. Blondlot, the French scientist, has lately been making experiments with these rays, and has published some of his conclusions. It has been established that most of the artificial sources of light emit radiations capable of traversing metals and a number of other bodies opaque to light—that is to say, radiations affecting the eye as light. These rays, which are distinguished by the name of "N," enhance the phosphorescence of phosphorescent substances, and Mr. Blondlot has employed this fact in trying whether such rays are emitted by the sun. With this object he placed a tube of phosphorescent material—for example, sulphide of calcium—behind an oaken panel or shutter, closing a window exposed to the sun, and keeping the chamber dark. If, now, a plate of lead, or even the hand, be interposed between the shutter and the tube the phosphorescence diminishes, and when the plate is withdrawn it increases. The panel of oak had a thickness of 15mm. The phosphorescence is rather feeble at first, and a sheet of black paper may be held as a background to the tube. Plates of aluminium and cardboard between the shutter and the tube do not prevent the phenomenon. The "N" rays from the sun, it was found, can be concentrated by a lens of quartz. They are reflected by polished glass and diffused by ground glass. Like the "N" rays from a Crookes tube, or a flame, those of the sun act on a small spark and a tiny flame so as to increase their brightness, but the experimenter has not obtained any photographic effect from these rays.

The Victoria Falls.—Our readers are cognisant of the scheme for turning to account the immense natural forces of the Victoria Falls, in Rhodesia, for electrical purposes. We have on more than one occasion in these columns spoken of the almost inexhaustible energy which these falls—in comparison to which those at Niagara sink into something approaching insignificance—contain, and only await the latest devices at the disposal of man to be converted into a source of indigenous wealth and prosperity to the country. The initial survey of the falls has yet to be made, but a rough estimate has placed the energy that might be harnessed at several hundred thousand horse power, at present running to waste. This may easily be imagined when it is stated that the falls are over a mile in breadth, and considerably higher than Niagara Falls. An interesting statement was made regarding the possibilities of the scheme at the meeting of the African Concessions Syndicate, which owns the concession. Although the proposal has not yet taken definite form, the concessionaires have already defined a very wide market for the electric power. A great deal, of course, depends upon the distance the current can be conveyed; but in America they have accomplished great things, and it is thought, profiting by their experience, that it will be possible to transmit power within a radius of 300 miles from the falls. This would embrace all the principal mining grounds round about, including the Waukie coalfields, the Gwelo, Sebakwe, Selukwe, Lomagunda, and Hartley goldfields, the Northern copper discoveries, and some 800 or 900 miles of railways. It will be seen, therefore, that the field open to electric power in the neighbourhood of the Victoria Falls offers splendid prospects, and on the face of it fully warrants the scheme being energetically pushed forward. It must take some years, however, before the scheme is in operation, but when accomplished it should play an important part in the development of what is still a comparatively new country.

Engineering Standards Committee.—Mr. Leslie S. Robertson, the secretary of the Engineering Standards Committee, has issued an interesting review of the work of the committee since its appointment some three years ago. In that time no fewer than 27 committees have been at work with 170 members, including 25 representatives of Government departments, and the results of their labours are so far very satisfactory. For instance, in the matter of tramway rails the sub-committee have agreed upon a series of standards which have been approved by the Board of Trade and have been rolled abroad, and the report of the sub-committee on railway rails is nearing completion. The standardising of electrical plant is presided over by Sir Wm. Preece, and four sub-committees have been doing much useful work. The sub-committee on generators, motors, and transformers have been collecting evidence for the determination of standard voltages and frequencies, and also the standard sizes for dynamos and motors. The other electrical committees deal with such subjects as cables and conduits, telegraphs and telephones, and the temperatures of insulating materials. It may be mentioned that the French Government have sent over a commissioner to study the procedure and the lines upon which the Engineering Standards Committee is organised.

Digitized by Google

Mr. Robertson concludes that "the epitome sufficiently indicates the enormous importance of the work in hand to the trade of the Empire. The Premier, Mr. Arnold-Forster, Sir John Wolfe Barry, and others have expressed opinions as to the immense value of its labours, the result of which it is difficult to over-rate if they are loyally supported by the trade and commerce of this country, as by the Government and its various departments." It may be added that the example of the Government in granting £3,000 towards the expenses of the committee has been followed by the leading manufacturers, who are also subscribing to the support of the movement.

Water Power in Switzerland.—There have been many proposals put forward for operating the whole of the railway system of Switzerland by electricity obtained from water power. Different engineers have their different ideas and prejudices, but however far removed from each other they may be on the question of the particular system of operation to be adopted, there is very general agreement as to the practicability of and necessity for changing from steam to electrical working. The chief cause for this is the recent rise in the price of coal, which leaves little margin on the right side between revenue and expenditure, besides which it is generally conceded that the almost illimitable water power, a great part of which is at present performing no specific function in the Swiss mountains, offers opportunities such as are to be found in very few countries. The latest exponent of a scheme having for its object the use of electric energy on the Swiss railways furnished by hydraulic plants is a Mr. Thormann. He estimates that the five main railways in the country would require over 30,000 h.p. daily, but that in order to organise a complete electric system it would be necessary to obtain about double that horse-power in the shape of alternating current of high tension, not counting the reserve plant, which is indispensable. Already there exist 21 large hydraulic plants capable of giving an aggregate of 86,000 h.p., and there are a large number of falls in the country which have not yet been taken advantage of. Mr. Thormann estimates the total cost of changing over to electric traction over the whole railway system at some 32 millions sterling, which includes eight millions for rolling-stock and ten millions for sub-stations. Coal has to be imported into Switzerland, there being no home supply, and it is to be noted that the adoption of electric traction, although involving a huge cost, would have the great advantage of dispensing with the present large importation of coal. The scheme is undoubtedly practical, and one which the Swiss Government very rightly cherishes as the future salvation of the State railways.

Telegraphs and Telephones in New Zealand.—Marked progress in the telegraph and telephone fields is shown by the annual report of the Post and Telegraph Department of New Zealand, and it also indicates a general increase in the electric power and lighting industries of the colony. The period considered is the 12 months ended March 31 last, and the total value of the telegraph and telephone business for the year amounted to £241,964, compared with £228,404 for the previous year—an increase of £13,560. During last year there were over 4½ millions of messages exchanged over the various lines, an increase of 391,323. Of the total number of telegrams, 4,271,218 represent the paid traffic, producing a revenue of £149,044. This amount, compared with the revenue from paid telegrams for the year ended March 31, 1902 — £137,616 — shows a gain of over 8 per cent. There were 22,672 miles of wire in operation at the close of the present fiscal year, as compared with 21,705 miles the previous year, an increase of nearly 1,000 miles. As regards the telephone business, the number of central exchanges increased during the year from 23 to 26, and the sub-exchanges from 35 to 44. With this expansion there was an increase of 1,373 new subscribers, bringing the total up to 10,633. The exchange subscriptions for the year amounted to £58,410, an increase of £6,424 over the previous year. On March 31 last 8,727 miles of telephone wire were in operation, an increase of 960 miles during the year. Reference is made in the report to the completion of the British Pacific Cable, and it is stated that since the cable has been in operation the colony's telegraphic business has increased about 50 per cent. The average number of messages transmitted to and from New Zealand since the opening of the Pacific Cable has increased from about 425 to 600 a day. The report also records much activity in electric railway building and in electric light and power work, the principal places affected being Auckland, Wellington, and Dunedin. The applications for licenses for electric lighting of boroughs are on the increase. Many of the above schemes contemplate the transmission of power at considerable distances and at high voltages.

Paris Metropolitan.—The deplorable disaster which recently occurred on the Metropolitan Underground Railway of Paris has had its lessons. Mr. F. Poussel, reporter to the special commission of enquiry appointed to investigate the causes of the disaster, has drawn up a number of recommendations which in themselves are a complete condemnation of the methods of working adopted by the Paris company. Briefly, these recommendations state that the present method of traction is proved to be a public danger, and should be modified as soon as possible. Any outbreak of fire caused by a motor should be followed by the immediate isolation of the motor, and consequently its release from further service. Communication by telephone or speaking-tube should be established throughout the whole railway system. A permanent surveillance should be maintained on every platform. The company should establish the means of verbal communication between the employés of every train. The exit at every station should be rendered visible by a light which cannot be affected by currents of air, and specially clear signs should indicate the way out of the station. All these signs ought to depend for their illumination on a source independent of the current which supplies the trains and lights the tunnels. An alarm should be used to indicate the necessity for evacuating the platforms, and the company's servants should call out to the public the side of the platform on which they will find the exit. The fact that the special commission has found it necessary to make these recommendations is sufficient evidence of the total lack of precautions against accident up to the present, and a deplorable want of good organisation on the part of the management of the Paris railway. The sooner the company set about improving these conditions, the sooner will public confidence be restored in their railway. One would not think that the present time was particularly auspicious for applying to the public for more capital. But so it is, the company having decided on an issue of £1,000,000 at the end of this month, thus raising the capital to three millions sterling. There seems to be little doubt entertained about getting the money, for the Paris correspondent of the *Financial Times* says that, notwithstanding the heavy fall in the traffic receipts which has taken place as a result of the accident and the onerous expenditure which the new municipal requirements will necessitate, the issue will probably be subscribed entirely by the present shareholders.

THE DESIGN OF EXTRA HIGH TENSION SWITCHGEARS.

BY W. E. WARRILOW.

(Concluded from page 316.)

If it is required to make this change without breaking the circuit, a set of parallel contacts are provided which admit of the insertion of a plug, current passing through this while the fuse is being replaced. In Fig. 24 the arrangement of the fuse under the switch gallery is shown, as well as the main portion of the gear, and it will be noticed that a clear space is left above the top of the fuse pot, as explained previously. The switch used with this form of board is also of the oil-break type, and its external appearance will be gathered from Fig. 25, which represents

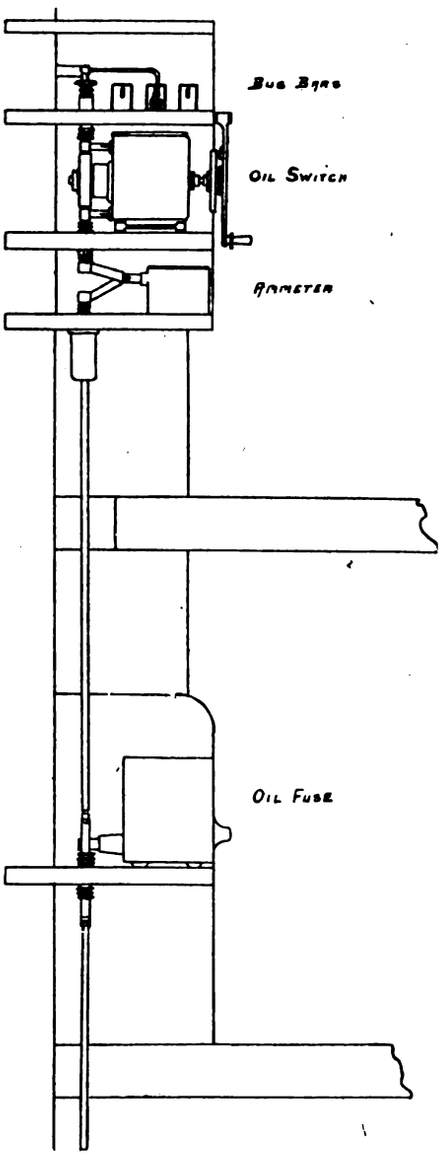

FIG. .—Cellular Gear, showing Mounting of Fuse.

the device with lid on and off, the latter photo being taken with the oil removed to show the contacts. A large porcelain box is used, in a similar manner to the fuse, to contain the oil, the moving and fixed contacts, and also to act as an insulating medium to all the parts of the switch. Two breaks have been provided for—the main break, carrying all the current during the time the switch is closed, and the shunt breaks, fitted inside the pot, and arranged to be left in circuit after the dry break has left its contacts. Referring to the section of the switch in Fig. 26 will make the arrangement quite clear. A steel spindle passes through the box at its centre, and one end of this shaft is fitted with the operating handwheel at the front, while the rear end has the main contact securely fixed to it. The central portion within the pot carries a loose drum, formed of a steel tube on which are clamped the shunt contacts, the rear portion of the drum having an enlargement provided for the spring and catch motions. These latter have been introduced to ensure a quick break under the oil, and comprise a laminated clock-spring fastened at one end to the spindle and at the other to the drum. A weighted catch, fixed to the oil-gland and having a projecting lug for tripping, drops into a notch on the enlarged part of the drum, which remains in the "on" position, with its contacts, until a pin on the spindle, engaging with the trip on the catch, throws this up and allows the energy stored in the spring to be expended in turning the drum round. The main contacts outside the pot will have in the meantime been turned almost at right angles (or horizontal) during the half revolution of the spindle which is necessary to open the circuit. The principal insulator used in the switch is ambroin, which is moulded round the main contacts to prevent flashing from one terminal of the switch to the other. The driving disc is of the same material, and also the plates carrying the fixed auxiliary contacts on the inside of the pot. The building-up of the revolving drum with its connecting blades has been effected by sliding ambroin washers and brass blades alternately over a sleeve of similar insulating material moulded in

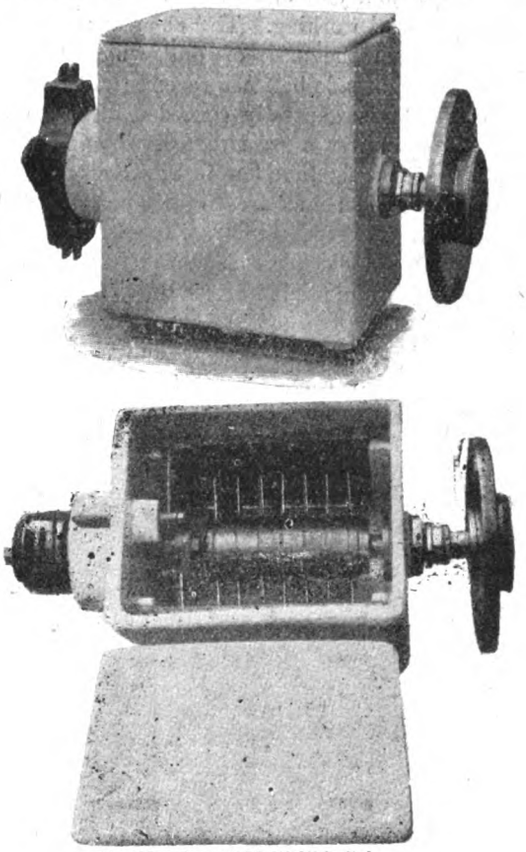

FIG. 25.—Ferranti Multi-Oil Switch.

hexagonal form on the steel spindle. There is no danger from shock in operating the switch, and no noticeable leakage takes place to the metal portions of the apparatus—in fact, every precaution has been taken to render all exposed parts absolutely safe. The oil-level is maintained above the contacts about 4in., and the body of liquid thus obtained effectually quenches the arc formed when the circuit is broken. The auxiliary breaks are arranged to split the arc between 14 points or gaps, these all being in series with one another, and by this means a reliable method of securing a long break is obtained. Suitable glands are fitted for the operating spindle to prevent oil leakage, and the complete switch is designed to draw out of its panel for examination or repair, and it can be replaced by another of similar make in a few minutes. The shunt connection is made at the top and bottom contacts of the switch panel by plugs which enter spring clips bolted to the contacts themselves, all parts being registered from the guide runners on which the switch slides. The operating handle is linked up to the driving disc, and is provided with stops on the lower slate which limit its travel to the correct distance necessary to the motion of the switch. When polyphase work is

Digitized by Google

dealt with, the discs are coupled together and driven by one central handle.

The ammeter used with the board is similar in design to that employed with similar gears of lower voltage—that is, it is placed directly in the high-potential circuit, and is made to be withdrawn from its particular panel without removing any connections. The case is of ambroin, and the front is shaped to suit the sweep of the needle over the scale, this latter being presented vertically edgewise towards the front of the gear. A projection at the back of the case carries the main coil, and a central hole is made in the projection which admits of the movement of a soft-iron plunger towards the centre of the coil. This plunger is pivoted to a parallel motion carrying the pointer, an oil dash-pot being included to check the violent action of the needle. The scale is fixed on edge at the front of the meter and the zero is at the top of the scale, so that the needle sweeps in a downward direction when reading.

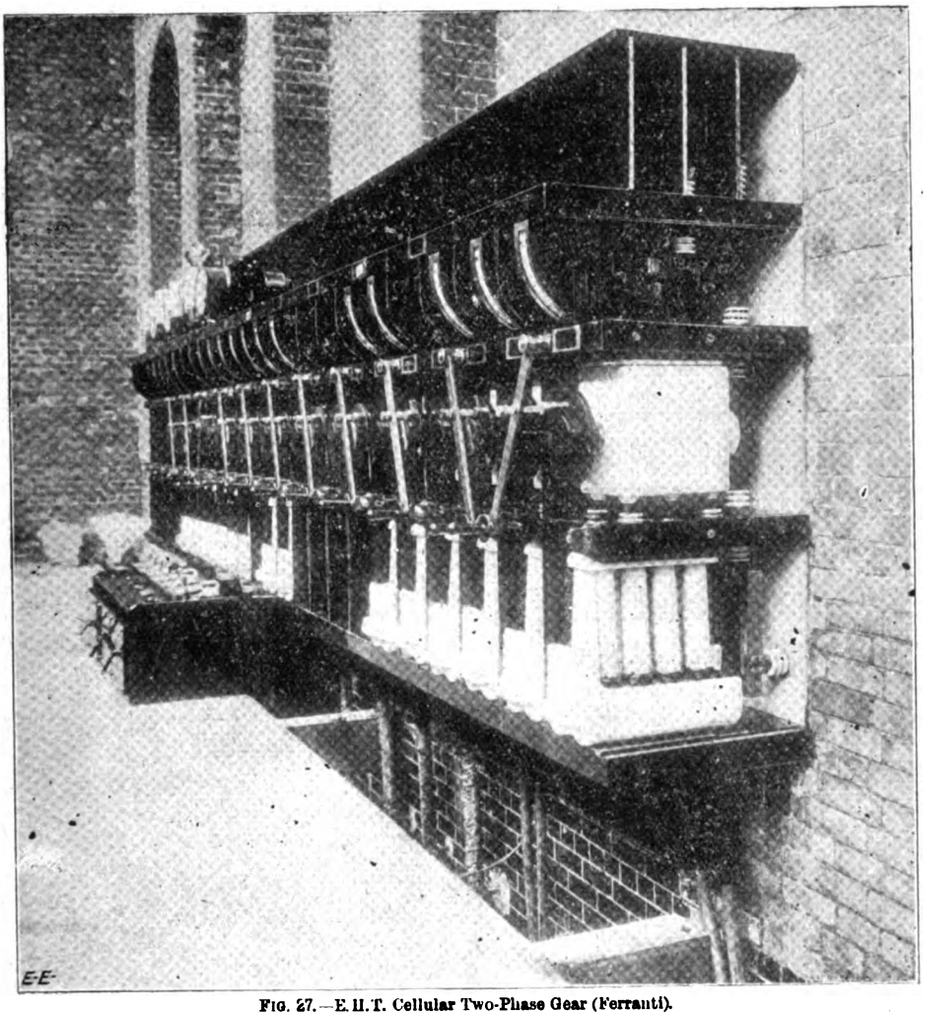

FIG. 27.—E.H.T. Cellular Two-Phase Gear (Ferranti).

The instrument operates without the aid of a current transformer, and by reason of the contacts which project from the coil at the back, it can be pushed into its panel or removed therefrom in a few moments. A zero adjustment is obtained by a small ebonite screw turning in a nut cemented into the lower slate, the screw point touching the front part of the case, so that the meter can be moved vertically on account of its contacts being of the clip type.

In the assembly of this gear a number of horizontal slates are cemented into the wall to form supporting ledges for the various fittings, and the whole combination is divided into any number of cells by the use of vertical division slates, which slide in grooves cut at right angles to the wall in the horizontal slabs. This method of construction enables the particular switches, fuses, etc., forming a complete panel to be maintained in a vertical straight line down the board, and the indiscriminate dotting of the parts about is entirely avoided. This last-mentioned feature not only greatly simplifies operation, but tends to lessen the chance of mistakes, while it affords a ready means of reducing the space occupied by the complete gear. In Fig. 27 a board for controlling a number of two-phase feeders and generators is shown, and the construction of the gear will be readily understood. At the top is the 'bus-bar chamber, capable of containing from one to three bars. Each bar is supported on insulators in the top slate (and not in the wall), and complete isolation from adjoining bars is obtained by ambroin plates running parallel to the wall, and held in position by a slate which forms the cover to the chamber. Directly below the 'bus bars are the ammeters, and their top contacts projecting into the bar chamber, admit of connection to the bar by a removable plug passing through a socket on the bar and entering a hole in the ammeter fitting. The withdrawal of this plug completely isolates the particular panel, which it connects to the bar, from the live bar, so that inspection or cleaning can be readily carried out. The ammeters below the bars are fitted to their respective panels, as already described, and below the instruments the switches are placed. The operating handles project from the slate slightly, and are moved in a direction parallel to the length of the gear. In its passage from "off" to "on" the handle engages with a small switch, closing the circuit of the synchroniser (low tension) and placing the particular generator in connection with the synchronising transformer. This switch is only fitted to dynamo panels, and corresponds to the "half-cock" position common to gears of this class. A front view of a similar board is illustrated by Fig. 28, and the arrangement of the fuses can be seen below the switch panels. This form of fuse is of smaller capacity to that described above, and is incorporated with the main gear, and not set apart from it, as is the case with larger fuses. A cable receiver is mounted underneath the lowest slate, to permit of a neat connection being made to the conductors from the generators or feeders. The feeder panels are fitted with a volt indicator, taking the shape of a vacuum tube, so connected as to glow when the cable is

Digitized by Google

charged, thus informing the switchman if the switch is closed at a sub-station or some other outside spot on the line. The generator panels are also fitted with a regulating table mounted on the gallery floor and projecting from the main board to facilitate operation. A rheostat hand-wheel, field ammeter, and field switch are fitted to each dynamo table, the resistance proper being fixed in the most suitable position below the gallery. The voltmeters and synchroniser stand on the slate in front of the 'bus-bar chamber, where they can be easily seen, and are also out of harm's way. The voltmeters are electrostatic, protected by a special device known as a water resistance cut-out, comprising a glass tube containing a column of water and a suitable holder with contact clips. The device protects the voltmeter in case of sparking taking place across the vanes, the momentary current passed under such circumstances causing the water to escape through a rubber valve at the bottom of the water-tube. The synchroniser with a portion of its transformer is mounted between the voltmeters, and its high-tension windings are protected by a removable oil-break fuse. Wattmeters are fitted to the gear to register the energy passing from the dynamos to the feeders and also to a motor-generator occupying a panel in the centre of the gear. The boards described are suitable for dealing with pressures up to 12,000 volts and currents ranging from 10 to 100 amperes, the various capacities being met by two sizes of panel, one of 9in. centres (Fig. 28) and the other of 12in. (Fig. 27) centres, these figures being the width of the panel in each case.

A comparison of the foregoing example of extra high pressure gears will serve to illustrate the manner in which various makers' ideas are worked out in practice as well as indicating the improvements which have been effected. The control of such high potentials is a matter of extreme importance, now that the recognised wants of the industry lie in the direction of large power stations distributing energy over wide areas. In conjunction with the essential features of safety and space occupied, the continuous efficiency of the board has to be considered, as breakdowns for even short periods result in disastrous consequences. The shutting down of a 10,000-kw. station through failure of the controlling appliances does not bear contemplation, and even the stoppage of one plant would seriously affect a large number of consumers. The types of gear described in the foregoing lines clearly point to the transitory condition of switchgears for high-pressure control, and in many ways bring home the fact that this portion of the station equipment has not received the share of thought as has been bestowed on the generating plant proper. Unless some decided steps are taken to level the development of this section of the station plant, the power-houses of the immediate future will be supplying current from first-class plant through controlling apparatus unfitted to deal with the demands likely to be made upon it. The designs which were suitable for dealing with pressures to 3,000 volts are

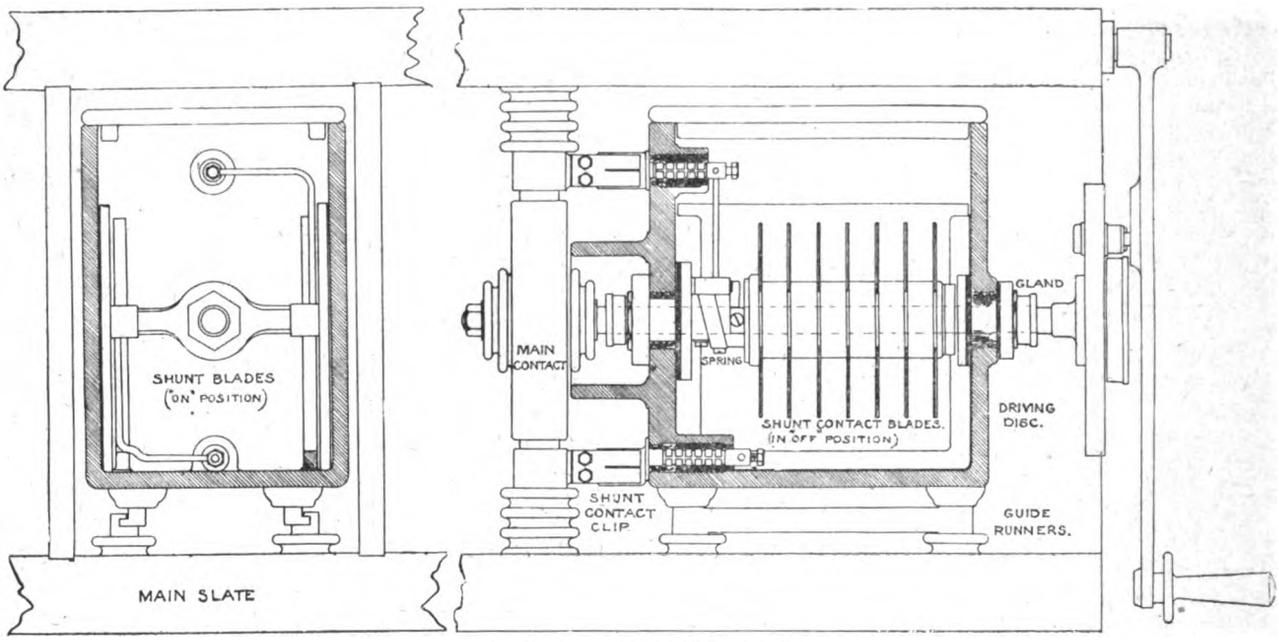

FIG. 26.—Ferranti Multi Oil-Break Switch.

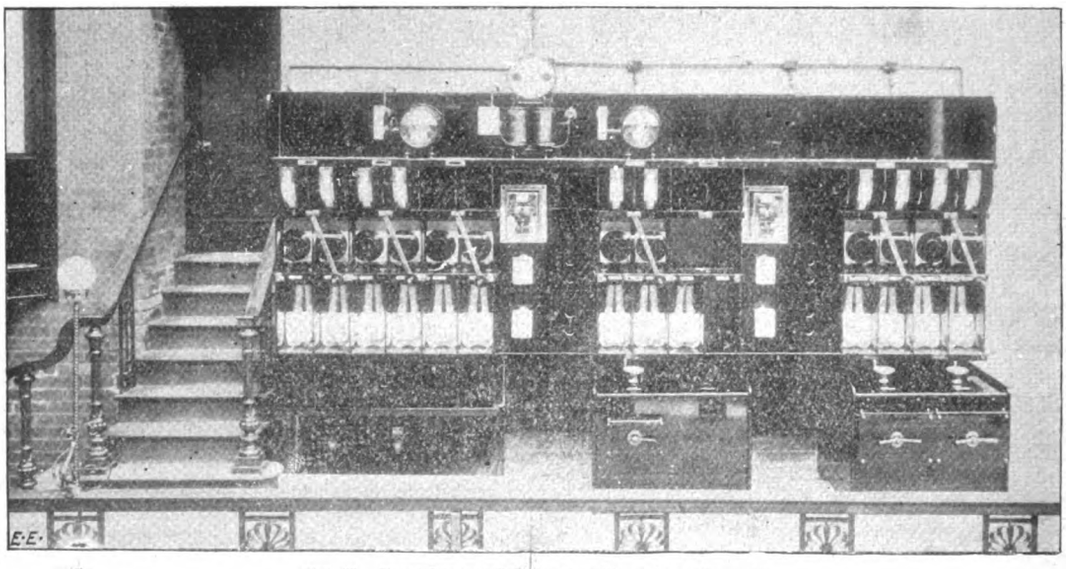

FIG. 28.—Front View of Cellular Two-Phase Gear (Ferranti).

Digitized by Google

totally unfit to control higher voltages, and the principle underlying the construction of such gears will also serve no other purpose. This is, of course, only to be expected, but it is nevertheless noticeable that many, in fact, most, of the boards now made are based on the earlier types.

For controlling currents at pressures to about 10,000 volts, experience seems to uphold the arrangement of the panels in concentrated form, and for this reason no doubt the cellular gear has met with extended favour. Beyond this limit of pressure, however, there is a growing tendency to return to the isolated type of gear, once used in single-phase stations, this consisting of a set of switching appliances for each machine placed directly in line with that particular unit in the station. The chief difference in the two methods is found in the system of operation. The old type had a long gallery, and necessitated considerable attention from the electricians, whereas the new form, though scattered as regards the apparatus, is concentrated in the means of control, this being effected from a central board fitted with either levers or switches, according to the operating medium adopted. American experience with these distance control gears seems to be of a favourable nature, and most of the very large power schemes have been equipped with them. The enormous output dealt with certainly justifies something elaborate in the controlling arrangements, and it would seem as if this was fouud in the electrically-operated gear.

In examining the position of affairs logically, there can be little doubt that the extra high tension gear will resolve itself into some definite form of electrically-operated apparatus, situated in an isolated position, which will be kept under strict supervision, though only by those authorised and competent to do so. A close inspection of a lay-out of one of these gears points to a distinct consideration of the factor of safety, and as the whole of the controlling switches and indicating instruments are placed in a low-tension circuit, the risk of shock to the operator on the gallery, at any rate, is reduced to a minimum, though there would still be doubts as to the safety of the electricians handling the extra high tension portions of the arrangement. The vexed question of the advisability of fuses in the high-tension circuit will probably never be satisfactorily settled, though there are prospects of the fuse receiving its death-blow from the electrically-operated switch. The latter has been successfully built to open the circuit automatically, and can be relied upon to deal with either overload or reverse-current occasions in a manner which no fuse could ever equal. The fuse must always be a clumsy device, and one difficult of immediate replacal, no matter how effectually it may open the circuit; and should the high-tension circuit breaker come into extended use, the necessity for a separate switch and fuse will at once disappear. It must not be thought for a moment that fuses will not continue to be employed, as they have a sphere of action peculiar to themselves, and must remain an integral part of switchgear for some time to come. The point for emphasis is, that the combination of a switch and fuse (or some automatic means of interrupting the supply) when successfully accomplished, as in the majority of electrically-operated switches, will so materially reduce the working parts of the board as to admit of no return to two separate devices performing the same operation. There seems to be little doubt now, that the oil switch is the correct device for safely opening the circuit, and flare switches, though still much used for medium voltages, cannot be continuously relied upon to break the arc they occasion when connected to extra high tension lines. It is not often that the oil fires in carefully designed apparatus, and when it is contained in tanks which lower away from the mechanism there is practically no leakage.

It is not intended in this article to deal with the connections of these gears, as that is a subject requiring separate consideration, but it may be noted that in the case of generators little or no provision is made for isolated running, as it is impossible to increase the number of 'bus bars in a polyphase station in the same manner as has been done with some single-phase. The machines are run in parallel, and though a duplicate set of bars may be provided, this number is seldom exceeded.

In looking back on the past and forward into the future, there is a decided prospect of a standard switchgear being produced for controlling extra high tension currents, but it is difficult to speculate on the merging of present designs into such a standard yet awhile. The principles underlying the design may become grounded within the next few years, but there would yet be that variety of production which a competitive commerce gives to every manufacture. Still, even before that state of affairs exists, much now considered of value will need to be discarded, and many pet theories, dear to the hearts of professors and consulting engineers, will be ruthlessly trampled under foot. The issue of *carte blanche* to manufacturers would, it is not too much to say, do a great deal to free the market from designs which can only act as a hindrance to the industry rather than a help. It is in the development of the large power schemes springing up on every side that the solution of the switchgear problem will be found, and the present tendency to adopt the distance control board will, no doubt, be then fully justified.

A NEW SINGLE-PHASE MOTOR.*

Since the polyphase alternating motor has come into general use, attempts have often been made to apply the principle of a rotating field to single-phase motors. It is well known that a polyphase motor can be driven from single-phase mains if it is first brought up to full speed, the rotary field being maintained by the rotating short-circuited rotor. The difficulty, however, lies in starting, as the rotating field must be artificially produced at first. This is usually accomplished by employing an additional starting winding, and setting up a current in the starting winding which is out of phase with that in the main winding. At the best, however, the phase difference, and consequently the starting torque, cannot be made large. Normal torque with double the normal current at starting seems to be about the best result obtainable with these split-phase motors, and this is insufficient in many cases, such as crane and traction work.

Through this endeavour to discover a workable rotary-field single-phase motor another type, the repulsion motor, has been somewhat overlooked. This is also partly due to the fact that after the simplicity of the short-circuited rotor, there is a distinct objection to introduce a commutator into alternate-current motors. The advantages obtainable by the aid of a commutator are, however, considerable.

The working principle of the repulsion motor may be explained by the aid of Fig. 1—*a*, *b*, and *c*. The two-pole magnet shown diagrammatically is excited by means of an alternating current, and the short-circuited armature is consequently acted upon by an alternating flux. The induced alternating current is, owing to the high self-induction of the coils, almost 90deg. in phase behind its voltage, and since this voltage is, of course, about 90deg. in phase behind the flux, the induced armature current is approximately in phase with the flux. A pull is, therefore, exerted in the direction of the arrow on those armature wires which lie under the pole (Fig. 1 *b*). If left to itself, the coil would set itself in such a position that no current was induced in it—*i.e.*, in the position shown in Fig. 1 *a*. The current is a maximum in the position of Fig. 1 *c*, but there is no torque in this position, as the wires under the two poles oppose one another. The maximum torque occurs when the product of current into number of wires under one pole is a maximum, which is approximately the case in the position shown in Fig. 1 *b*.

In order to obtain a continuous torque, a continuous armature winding must, naturally, be provided and arrangements made to maintain the relative position of the short-circuited coils and the magnetic axis constant. For this purpose an ordinary continuous-current armature with commutator can be employed. The brushes are permanently short-circuited, and, by shifting them, the relative position of the short-circuited coils to the magnetic axis can be altered at will (Fig. 2).

* L. Schüler in *Elektrotechnische Zeitschrift* for July 16, 1903.

Digitized by Google

Up to the present the armature has been assumed to be at rest, and the armature current strength under these circumstances is determined by the flux passing through the coils and the resistance and self-induction of these coils. When the armature is in motion, however, the wires under the poles cut the flux. The voltage induced in this way reduces the armature current, so that as the speed increases this gradually falls. At the same time the torque is, of course, reduced until a speed is reached at which the armature current is just sufficient to produce the torque required. Such a motor is consequently far from being a constant-speed one, like the rotary-field motors. The speed, on the contrary, depends on the load.

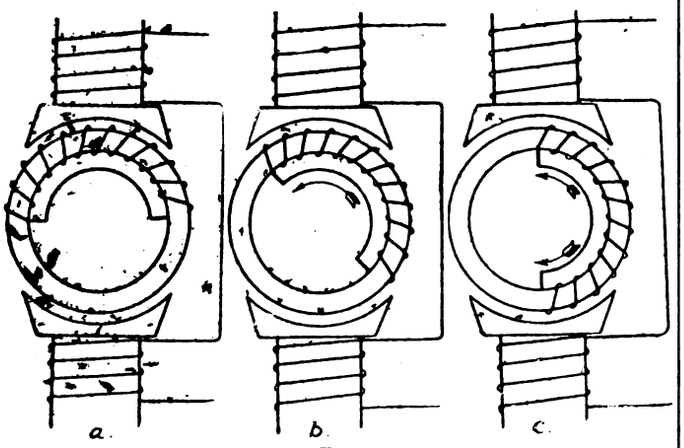

FIG. 1.

The commutation of a repulsion motor is naturally less satisfactory than that of a continuous-current machine, as the coils short-circuited under the brushes are traversed by an alternating flux, which tends to set up large short-circuit currents, which cause sparking. By employing a large number of commutator segments, and by inserting resistances between the winding and the commutator, these short-circuit currents can, however, be kept within reasonable bounds. There is, besides, a method of entirely avoiding this harmful short-circuiting current. It consists in the use of a so-called Weston winding, in which two distinct windings are used on the armature, the commutator plates being connected alternately to one and the other winding. If the brush width is made small enough to touch no more than two sections at one time, no coil will become short-circuited, since neighbouring segments belong to different windings. There are, however, practical objections to this method, such as the extreme accuracy with which the brushes must be set, so that an ordinary winding is usually preferable. In practice, a repulsion motor can be made as sparkless as a fairly good continuous-current machine, and it is a mistake to suppose that this sparking difficulty forms the principal bar to the more general introduction of such motors.

Turning next to the question of the torque produced by a repulsion motor, the writer preferred to deal with the question experimentally rather than analytically, and so constructed a motor whose principal dimensions are shown in Fig. 3 (dimensions given in millimetres). The armature had an ordinary continuous-current winding, but besides the ordinary commutator it was fitted with three slip-rings connected to the winding at three equidistant points. The object of these rings will be explained later. The magnets had no definite projecting poles, but were slotted continuously, and wound to produce six poles. The motor is of a size suitable for developing 5 b.h.p. at 960 revolutions (220 volts and 50 ~) if wound as an ordinary three-phase motor. The machine was first tested as a repulsion motor at 220 volts, and the connection between torque, current, and speed is shown in Fig. 4. The load can be found from the torque and speed. It will be seen that

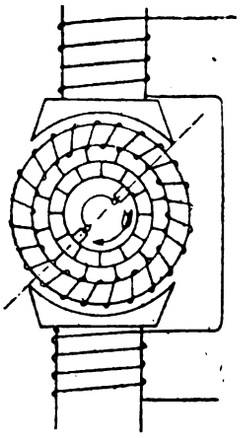

FIG. 2.

when at rest the torque is considerable, but falls off rapidly as the speed increases. The maximum power is developed at about 500 revolutions, and is about $2\frac{1}{2}$ b.h.p. The current is 50 amperes at starting and 26 amperes at normal load. The product of efficiency $\times$ cos ϕ is only 32 per cent. as a maximum. The cause of this unsatisfactory value is the high wattless component, which in repulsion motors is greater the greater the load on the machine. On this account it would seem impossible to construct a rational motor on the pure repulsion principle.

Since the repulsion motor is very satisfactory at starting, but not good when running, whilst, on the other hand, the rotary-field motor has just the opposite properties, the question of using the repulsion principle only for starting and the rotary-field principle for the normal running conditions at once suggests itself. The conversion of a repulsion motor into a rotary-field motor is a very simple matter: the only change necessary being the short-circuiting of certain commutator segments together so as to form a short-circuited armature. Such motors have been, in fact, employed in practice with more or less success. The American Wagner Company, for instance, employs an armature with a centrifugal apparatus fixed inside arranged to short-circuit certain commutator segments as soon as a certain speed is reached. The brushes are at the same instant automatically raised from the commutator. The same problem has been dealt with in another way by Deri. In his motor the exciting winding is arranged so that it can

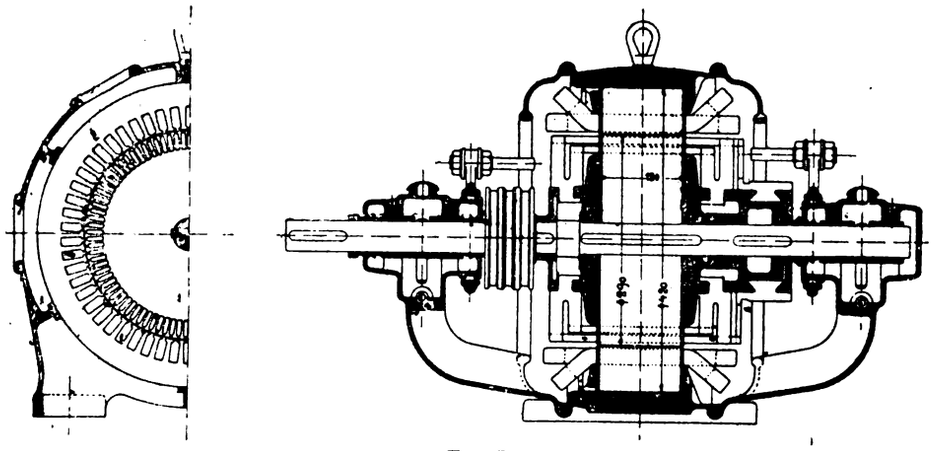

FIG. 3.

Digitized by Google

be coupled up for two different numbers of poles. The exciting wire can, for instance, be arranged for either four poles or six poles whilst the armature is wound for six poles, and consequently acts as if short-circuited when running in a four-pole field.

The machine can, therefore, start as a six-pole repulsion motor, and if the field is then converted into a four-pole one the machine will continue to run as a four-pole rotary-field one. The change over is accomplished by means of a special centrifugal apparatus operating when a definite speed is reached. The question next arises as to the correct speed at which to change over. It would, of course, be best to change over at the speed at which the machine will continue to run as a rotary-field motor—*i.e.*, at

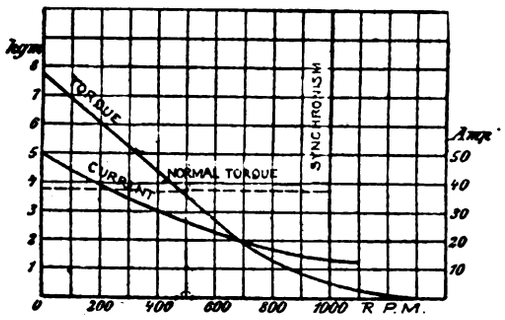

FIG. 4.

synchronous speed. It will, however, be seen from the torque curve (Fig. 4) that this is impossible, or at least only possible when running light. Since the motor is six polar and running off a 50 ~ circuit its synchronous speed is 1,000 revolutions, so that the change over would have to occur at about 960 revolutions. At this speed the torque is only ·7 kg.-m., or less than one-fifth of the normal torque corresponding to 5 h.p. If the motor has to exert a greater torque than ·7 kg.-m. at starting it will not reach full speed as a repulsion motor, and must be changed over at some lower speed. If starting at full torque, for instance, a speed of only 470 revolutions could be reached as a repulsion motor, and at $1\frac{1}{2}$ times full torque only 250 revolutions. After changing over at these low speeds, the machine must be in a position to exert the required torque as a rotary-field motor

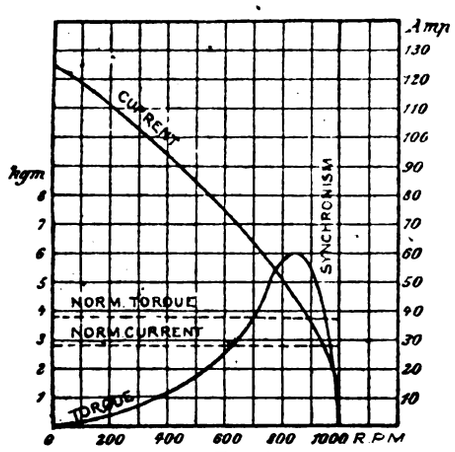

FIG. 5.

at the same speed. To decide whether this was feasible, the writer studied the starting characteristics of a single-phase rotary-field motor with short-circuited rotor experimentally. The same motor as before was employed, but the commutator was short-circuited by means of a thick wire band. The relation of torque and current to speed is shown in Fig. 5. The curve shows what is well known—viz., that when at rest there is no torque, and that the torque only becomes considerable in the neighbourhood of synchronism. On the other hand, the current is excessive when at rest and falls gradually as the speed increases.

Suppose the motor is required to drive machinery taking 5 h.p. normally, and a torque corresponding to double this horse-power at the instant of starting. Fig. 4 shows that the motor will start with 50 amperes and run up to a speed of 470, when the current will have fallen to 26 amperes. At this speed the change over should take place, but Fig. 5 shows that as a rotary-field motor the torque has not reached half the normal value at 470 revolutions, so that if changed over at that speed the motor would come to rest again. In other words, the motor is unable to exert its normal torque during the whole of the starting period. The starting conditions attainable with such a motor are shown in Fig. 6, which is a combination of Figs. 4 and 5. The change over is shown as occurring at a point at which the repulsion motor torque curve crosses that of the rotary-field motor—viz, at 610 revolutions. It will be seen that the torque drops as low as 2·6 kg.-m. (or to two-thirds of the normal), whilst the current reaches a momentary value of 74 amperes, or over $2\frac{1}{2}$ times the normal. Even

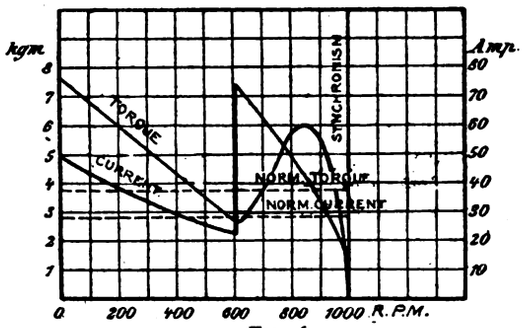

FIG. 6

neglecting the drop in torque, the large momentary current is very objectionable, on account of its effect on neighbouring lamps. This current can be somewhat reduced by increasing the resistance of the armature and the slip. As, however, the losses in a single-phase motor increase as the square of the slip, and the overload capacity falls in the same ratio, this method can only be employed to a limited extent.

It will, of course, be understood that the figures given do not apply generally, as they are experimental results for a particular motor. By strengthening the field, for instance, the repulsion motor torque could be increased, but, unless the dimensions of the motor are considerably increased, this takes place at the expense of the efficiency and power factor. The sparkless running of the machine also, to a certain extent, prevents a higher torque being attained.

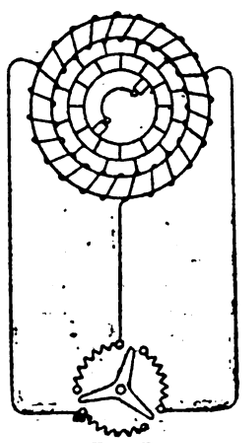

FIG. 7.

The motor employed for the tests was constructed to meet all requirements in the best all-round manner. It runs absolutely sparklessly at all speeds. Its efficiency is 79 per cent., and cos ϕ 78 per cent. The results obtained may, therefore, be considered as a fair example of such motors.

The improvement introduced by the writer consists in changing over from repulsion to rotary-field motor gradually by first connecting points on the armature winding together through resistances, which are then gradually cut out and finally short-circuited (Fig. 7). Two advantages are attained by this means: firstly, a rotary-field motor is known to be capable of exerting a considerable torque even at low speeds and currents if its armature is short-circuited through suitable resistances; and, secondly, the repulsion motor torque continues to be

Digitized by Google

exerted until the resistances are quite short-circuited, the machine thus working for a time as combined repulsion and rotary-field motor. The results obtained from the above motor employed in this way are given in Fig. 8. As mentioned above, this motor is fitted with three slip-rings as well as the commutator. These rings are connected to three points on the armature 120deg. apart. For the first test the slip-rings were connected to a three-phase starting resistance, and the torque and current for each speed were noted, the most favourable starting resistance for each speed being first determined. The resistances were short-circuited at a speed of 900. The advantage obtained can be seen by comparing Fig. 8 with Fig. 5. During this last-mentioned test the brushes were raised from the commutator, so that the repulsion principle was absent. When the brushes are down, both the current

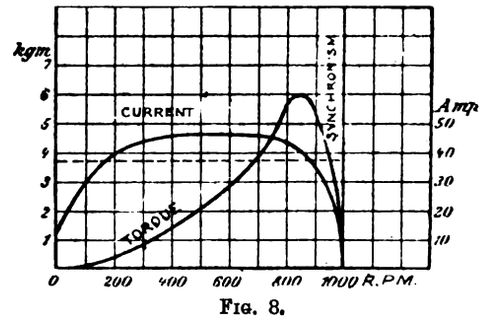

FIG. 8.

entering at the slip-rings and that entering at the commutator flow in the armature winding. It would be an interesting analytical problem to determine how these two currents combine in the separate armature coils, and what their resultant reaction amounts to. The writer has, however, confined himself to the experimental results, and these indicate that the value of the torque at each instant is approximately equal to the sum of the separate torques due to the repulsion and the rotary field actions.

The next test was carried out by permanently short-circuiting the commutator brushes together, whilst the slip-rings were gradually short-circuited as the speed increased. The measured torque and current at various speeds are shown in Fig. 9.

The motor has a torque at the instant of starting of double the normal, and at no time throughout the period of starting does it fall below 1·4 times the normal. The

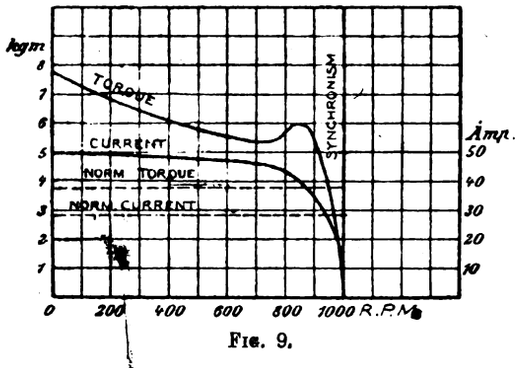

FIG. 9.

starting current, even at the first instant, does not exceed twice its normal value, and gradually falls off as the speed increases until it reaches the correct running value for the load employed. The objectionable instantaneous rush of current noticed with the ordinary change-over repulsion motor is entirely avoided. The speed of the motor can be regulated within a considerable range by inserting resistance into the slip-ring circuits, just as in the case of a rotary-field motor. This insertion of resistance has the effect of transferring some of the current to the commutator brushes, and the machine works as a combined repulsion and rotary-field motor. It is well known that in the case of an ordinary rotary-field single-phase motor no such regulation is admissible, as the torque falls off rapidly with the slip, whilst with the older type of change-over repulsion motor (Arnold, Deri) speed regulation is naturally impossible.

The practical construction of the motor is comparatively simple. The armature has an ordinary continuous-current winding fitted with a commutator and three slip-rings in the same way as a rotary converter armature. The commutator can be very small, as it only carries current when starting. If required, the commutator brushes can be raised when running, but, for the sake of simplicity, this would not usually be done. Fig. 10 is a photograph of the motor, which was constructed by Messrs. Ferranti Limited, Hollinwood, the holders of the English patents. The motor is started in exactly the same way as an ordinary induction motor with slip-rings; the main switch is closed, and then the armature starting resistance is gradually short-circuited. Occasionally the latter action is made automatic. As the motor is more especially suitable

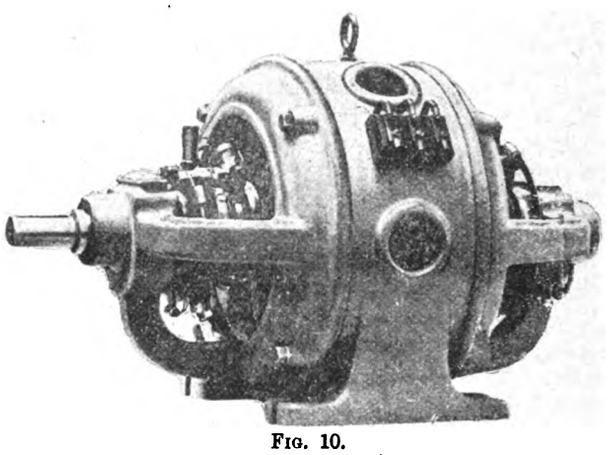

FIG. 10.

for crane and traction purposes, a simple method of reversing it is indispensable. A consideration of Figs. 1 and 2 will show that the direction of rotation depends on the relative positions of the axis of the field and that of the short-circuited armature winding. Reversal can, therefore, be obtained by simply moving the brushes through 90deg. If, however, brush shifting is inadmissible (railway work), two sets of brushes can be fitted—one for right-handed and one for left-handed rotation—and one or the other of these sets can be short-circuited according to the rotation required. Reversal can also be obtained by shifting the magnetic axis. Thus, two sets of exciting windings 90deg.

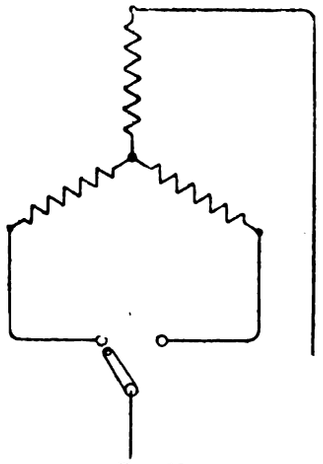

FIG. 11.

apart can be employed, and one or the other switched in to suit the rotation required; or a three-phase exciting winding could be employed, as shown in Fig. 11, and two out of the three phases employed for each direction of rotation. In this case the field is only shifted 60deg. instead of 90deg., but a saving in copper and in winding space is effected.

The first-mentioned method of reversal, by means of two sets of brushes, possesses especial advantages in the case of high-tension railway motors, as by its means the controlling gear need not be connected in any way with the high-tension mains. There would, for instance, be no objection to building a 50-h.p. motor of this type for, say, 10,000 volts. There are no crossings in the exciting coils, so that these can be thoroughly insulated,

Digitized by Google

and as one end of the winding is earthed it is only necessary to connect one high-tension lead through a single-pole main switch and fuse to the trolley. The main switch is only used during the longer stops, and the whole regulation is consequently carried out on the low-tension winding.

THE EVOLUTION OF THE STARTING SWITCH.

BY A. H. M.

During the last five or six years the direct-current motor has made rapid and well-deserved advances in popular favour, and as a consequence the demand for starting switches has proportionately increased, and also the demand for improvements in them, the necessity for which has been demonstrated in the course of experience in the hands of both user and manufacturer. A glance at the principal defects of many starters dating some years back may prove of some value in assisting designers to avoid errors of the past.

A mistake frequently met with was that of dividing up the resistance into too small a number of sections, frequently only three or four, the consequence being (even in those days of low-voltage supply) that the potential difference between the contacts was so great that disastrous sparking took place when working, and also the acceleration of speed of the motor was too violent from step to step. Another error was that of dividing up the rheostat into equal parts as regards ohmic resistance; as an instance, if the total resistance was 40 ohms and the number of contacts on the switch five, then 10 ohms would be allowed between each contact, with the result that the motor would not have nearly attained its full speed when the switch arm reached the last contact but one; and when this last section was cut out and the full voltage of the circuit came upon the motor terminals, a rush of current would momentarily take place, with sparking at the brushes. The most up-to-date manufacturers have now realised that about eight to ten contacts is the average number required for a satisfactory starter, and also that the resistance value of the sections should gradually decrease towards the "all out," or armature contact, in order that but very few volts may be absorbed by the last one or two sections.

A necessity which speedily made itself manifest was that of providing some mechanism for causing the switch arm to return to the "off" position should the supply of current to the motor cease from any cause—such as the melting of a fuse. In such a case the attendant would probably open the main switch, replace the fuse, and then close his main switch again, entirely forgetting that all resistance was cut out of the armature circuit, and with results which may readily be imagined. A considerable number of devices for effecting this purpose have been introduced by various makers, but the best and simplest is undoubtedly that of an electromagnet, the winding on which is in series with the shunt coils of the motor, and against the poles of which the contact arm rests when in the running position—thus being held against the action of a spring. The above device has the recommendation of being extremely simple—in fact, cannot fail in its action, as there is no mechanism to get out of order.

Although performing its own particular duty in a thorough manner, this device does not prevent the motor from being overloaded, and various attachments were invented for this purpose, the principle of the action being in most cases an electromagnet, the winding of which is in series with the main motor circuit, and an armature lifted by it when the current exceeds a certain value, the lifting of the armature closing two small contacts, and short-circuiting the coil holding the arm, thus allowing it to fly back and stop the motor. The writer has had some experience of these various forms of "overload preventers," as they are termed, but must candidly say that he has not found them sufficiently reliable in their action to be of much practical value. When quite new and properly adjusted they are useful enough, but one prolific source of failure is that after a time the hinge upon which the armature works becomes clogged with dust or oil, and it then requires a dangerous excess of current to move it. Of course, some means must be provided for preventing the motor suffering from excess current, and this should undoubtedly be effected by the provision of a properly-rated and easily-renewed fuse, and where the cost does not render it prohibitive, by the addition of a circuit breaker, which should be set to open the circuit at about 15 per cent. less current than the fuse will carry, the golden rule in this connection being—never omit the fuse.

Another item of great importance in every switch are the contacts, and although these have undergone but slight change during the last few years, and are not altogether satisfactory, it is not easy to see in what direction improvement is to be effected. For currents up to 40 or 50 amperes the round button contacts do fairly well, but a carbon point should always be fitted to take the spark at the final break, For heavier currents, hard-rolled brass segment-shaped contacts should be provided, these exposing a considerable area of contact, and being, in the writer's opinion, superior to copper, as they are more easily kept clean.

Whilst upon this point, it is important to emphasise the fact that if the contacts never receive any attention (as is so often the case) excessive sparking is bound to occur, and the arm is very likely to stick when half-way over, and cause a burn-out of the resistance. The occasional application of a piece of emery cloth will keep the contacts in good order and prevent accident. The contact-making device on the arm is frequently a flat springy piece of copper, but where the current exceeds 25 amperes this is far from satisfactory, as the front edge soon becomes fused and curled up, and is liable to stick. A more satisfactory substitute is a spring-controlled block of carbon, which is finally cut out of circuit when the arm is in the running position. For currents exceeding 60 amperes the carbon block alone will not suffice, but must be assisted by a copper contact piece, to reduce the sparking and heating, and the relative positions of the two must be such that the make and break on each contact is taken by the carbon. The success of the electric motor in our works and factories has largely depended upon the fact that it lends itself to a subdivision of power that could not be accomplished by any other means, and it therefore follows that the vast majority of starting switches are under 50 h.p. capacity, for which power the combination of carbon and copper contact blocks, with hard-rolled brass segments, will be found satisfactory.

In one extremely important particular the rheostat of to-day shows no improvement over that of 10 years ago; the writer refers to the resistance itself, which still consists of coils of iron or other resistance wire. The trouble which has always existed in connection with wire coil resistances is due to the fact that they cannot be made really substantial without being at the same time bulky and expensive, and the consequence is that they are usually constructed from the finest gauge of wire which will carry the current long enough to start up the motor, and such small gauges of wire are ill adapted to stand against the alternate heating and cooling they have to undergo. There is also another source of destruction, if anything more effective than the above—that is, the continual rusting process, which is always in progress and which soon causes a breakdown.

Many attempts have been made to introduce a satisfactory motor starter of the liquid type, but to the engineer the idea of a pot of liquid in connection with his work is objectionable. Apart from its messy character, there is always the fact to be dealt with that every time the starter is used the level of the liquid must be slightly reduced owing to vapour being given off when it is heated, and it therefore follows that the total resistance is constantly varied. Under certain forms of application it becomes absolutely necessary to provide some means of preventing the resistance from being cut out too quickly when starting the motor. This is particularly required in the case of motors of large horse-power the manipulation of which are in the hands of unskilled persons. The writer has had considerable experience with the various devices which have been evolved, generally consisting of some application of worm gearing, but has only recently found a really satisfactory slow starting attachment and one in which the human element is done away with. The device in question is simple in action, it merely being necessary to pull out a knob from the case of the starter, and the attachment then automatically starts the motor at any rate of cutting out which may be desired, and at which it is set to work. The above is combined with an automatic release action, and is described as Gibbings's patent. Where there is a

Digitized by Google

likelihood of switches being tampered with by irresponsible persons, a protective iron covering, allowing only the handle to project, is supplied by most makers on demand.

To briefly sum up, it appears that the essential requirements of a satisfactory starting switch are as follows: (1) the resistance must be of ample capacity and of lasting material; (2) the contacts and contact maker must be properly designed according to the current to be dealt with; (3) automatic release for no voltage must be fitted; (4) when the switches will be handled by inexperienced persons an automatic starting device must be provided.

RADIUM AND OTHER RADIOACTIVE SUBSTANCES WITH A CONSIDERATION OF PHOSPHORESCENT AND FLUORESCENT SUBSTANCES. THE PROPERTIES AND APPLICATIONS OF SELENIUM AND THE TREATMENT OF DISEASE BY THE ULTRA-VIOLET LIGHT.*

BY WILLIAM J. HAMMER.

(Continued from page 318.)

An interesting experiment is shown in Figs. 13 and 14. In the former experiment, I have placed strips of various metals such as brass, iron, copper, tin, lead, tinfoil, aluminium, platinum, magnesium, etc., and strips of

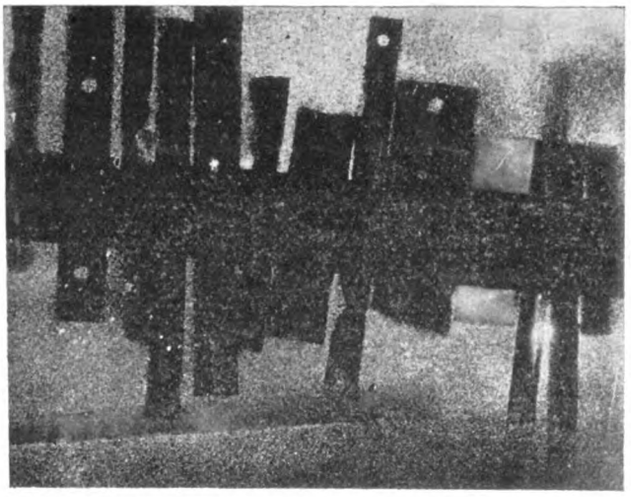

FIG. 13.—Photograph made by Phosphorescent Sulphide of Calc'um of Iron, Brass, Copper, Tin, Lead, Aluminium, Platinum, Tinfoil, Magnesium, Carbon, Glass, Mica, Celluloid, Vulcanite, etc., and Strip of Black Paper. (See Fig. 14).

carbon, vulcanite, glass, mica, and celluloid. Across the middle of the plate I have placed a strip of thick black paper cut from an X-ray plate envelope. I then sprinkled over the entire plate by means of a sieve sulphide of calcium, which I had made brilliantly phosphorescent by exposure to burning magnesium ribbon. The only substances which allowed the light to pass through at all were the glass, mica, and celluloid, the other substances, including the paper, being very opaque, showing apparently only the presence of ordinary light rays. This plate was placed for 24 hours in a dark room. In Fig. 14 are shown some substances similarly arranged, but exposed to a tiny tube of radium of 7,000 radioactivity, which was placed 3in. above the plate and near the centre. The exposure was made for 24 hours, and it will be noted that the strip of black paper has entirely disappeared, and the various substances underneath it have been penetrated to a greater or less degree, particularly those nearest to the radium.

A bibliography of "radioactivity," even at this early date, would be very extensive. Among the publications containing the most important contributions are the *Phil. Mag*, *Comptes Rendus*, *Ann. der Physik*, *Revue Gen. des Sciences*, *Nature*, *Jour. de Phys.*, *Soc. Francaise Phys. Bulletin*, *Chem. News*, *Phys. Ges. Verk*, *Phys. Zeit.*, *Science Abstracts*, *Wied. Ann.*, *Proc. Royal Soc.*, *etc.*

* A lecture delivered at a meeting of the American Institute of Electrical Engineers and the American Electrochemical Society, New York, April 17, 1903.

THE PROPERTIES AND APPLICATIONS OF SELENIUM.

The extraordinary property which selenium possesses of varying its electrical resistance on exposure to light is a phenomenon which has been known for a long time, but the commercial applications of this peculiar property possessed by selenium have not been properly appreciated up to the present time. It is my purpose to invite your attention this evening to a number of applications of selenium which the writer believes will prove of no small interest to the electrical engineering profession, and perhaps stimulate investigations in this most promising field. The Swedish scientist, Berzelius, discovered selenium in 1817, as a by-product from the distillation of sulphuric acid from iron pyrites. The proximity of the earth and moon suggested to Berzelius the name "selenium," after the Greek "selene" (moon), this being the result also of the striking similarity of the properties of selenium with those of tellurium, which is a term derived from the Latin "tellus" (earth). Its atomic weight is 79·5; specific gravity when crystalised, 4·788; its observed vapour specific gravity at 2,588deg. F. 5·68. It is a non-metallic element, which possesses characteristics similar to phosphorus, sulphur, and tellurium. When melted at 212deg. C. and allowed to cool rapidly, it forms a brown amorphous mass of conchoidal fracture. In this condition it is a high-class insulator. It has been said that a small piece of it would represent the resistance of a wire stretched from the earth to the sun. When heated for quite a time at a temperature of 100deg. C., selenium becomes a con-

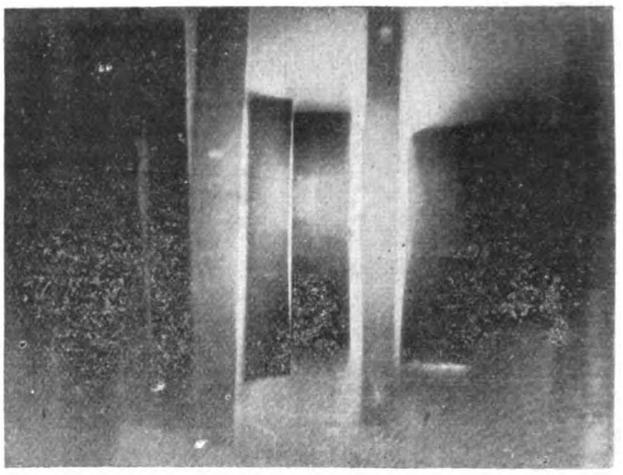

FIG. 14.—Radiograph made by Radium of same substances as in Fig. 9. Note Black Paper is Transparent, as are certain of the other substances, especially those directly below the Radium.

ductor of electricity to a limited degree, this increasing with an increase of current and varying according to the direction. Selenium has neither taste nor smell. The red vapour rising from selenium when subject to intense heat is exceedingly poisonous, and care should therefore be taken when experimenting with selenium in liquid form. Selenium is usually supplied commercially in a vitreous form. Here are some samples of it, and you will note that it is as structureless as glass and resembles black sealing-wax. I also have here some amorphous selenium in which form it is a finely-divided brick-red powder. This changes into vitreous selenium when exposed to a temperature of from 80deg. to 100deg. C. In order to obtain crystalline selenium, in which form it is useful for selenium cells, it must be kept, as already stated, at from 100deg. to 200deg. C. for some time, the black mass being changed into a hard slate-coloured metallic-looking substance. In this form even the thinnest films are opaque to light, whereas in the vitreous form the film would be transparent and ruby red in colour. I have some of these films here for your examination. Selenium is to-day employed to a considerable extent for the coloration of glass.

In 1851 Hittorf first discovered the effects of temperature on selenium, but it was not until Feb. 12, 1873, that Mr. Willoughby Smith sent a communication to President Latimer Clark, of the Society of Telegraph Engineers, of London, calling attention to the effect of light in reducing the resistance of selenium. An assistant of Mr.

Digitized by Google

Willoughby Smith—a Mr. May, who was a telegraph clerk at Valencia—called attention to the fact that some pencils of selenium, which had been used to give a high resistance in connection with some of the cable testing work conducted by Mr. Willoughby Smith, showed a marked change in resistance when the sliding cover of the box which held the selenium was removed and the selenium was exposed to sunlight. These selenium pencils varied in length from 5cm. to 10cm., and were 1mm. to 1½mm. in diameter; they were hermetically sealed in glass tubes with connecting wires of platinum at each end. Little credence was given to the original announcement, and it was only after Earl Ross verified this statement, and proved that the action was due solely to light, and showed the effects of the light of different portions of the spectrum, that it met with serious consideration. Since that time much work has been done in investigating the properties of selenium, especially by Messrs. Shelford Bidwell, J. W. Giltay, Lord Ross and Sale, Draper and Moss, Hittorf, Adams and Day, Ayrton and Perry, Sir W. C. Siemens, Dr. Werner Siemens, Mercadier, Fritts, Minchin, Ruhmer, Webb, Bell and Tainter, and many others. Alexander Graham Bell some 20 years ago made some interesting experiments with his radiophone, a diagram of which is shown in Fig. 15, in which a mica or glass diaphragm covered with a silvered foil was used to reflect a powerful beam of light upon a selenium cell placed in the focus of a silvered reflector. To the selenium cell were connected a pair of telephones and a battery. At the back of the silvered diaphragm was a flexible tube and mouthpiece, into which words were spoken. The sound waves causing the diaphragm to

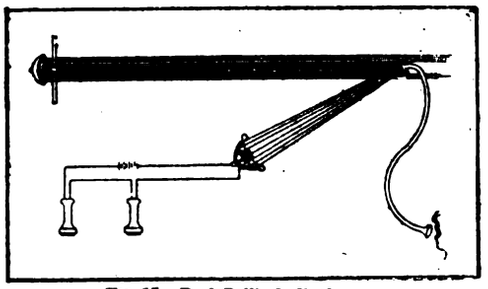

FIG. 15.—Prof. Bell's Radiophone.

vibrate sent pulsations of the reflected light upon the selenium cell, producing corresponding variations in its resistance and reproducing audible sounds in the telephone. Prof. Bell only used this over very short distances.

In 1898 Prof. H. T. Simon, of the University of Göttingen, discovered that an arc lamp, the circuit of which was in proximity to a telephone circuit, was caused to vibrate very perceptibly, and he devised his interesting speaking arc, by means of which he superimposed the sound waves produced by the telephone upon the circuit in which the arc was placed. He connected the lamp circuit with the secondary winding of an induction coil, the primary circuit being connected with the carbon transmitter, and a battery. The sounds thus produced originally were very weak; but by employing a suitable carbon microphone, the sound was reproduced to large audiences. Conversely, the arc could also be used in conjunction with telephone receivers to receive sounds. It is also found that the transmitter battery may be omitted, and a shunt taken from the arc circuit may be used with the transmitter and a suitable resistance. Again, this resistance may be displaced by storage batteries; and in this case, to secure the most satisfactory results, self-induction ("reaction coils") should be placed in the circuit of the arc lamp, allowing the direct current to pass without obstruction, but offering extremely high resistance to the alternating currents produced by the carbon transmitter. By compensating in this way any disadvantage in the use of the shunt is done away with. The transmitter may also be placed in shunt with the reaction coil instead of in shunt connection with the arc lamp, and this has the advantage that the rheostat used with the storage batteries may be omitted, provided the windings of the reaction coil are suitable for use as a resistance. By this arrangement the lack of self-induction in the transmitter circuit permits of a very clear and distinct reproduction, sufficient to be heard by large audiences. Mr. W. Duddell, of England, has made some most successful talking arcs, which the writer had the privilege of seeing in London over two years ago. In his arrangement in the secondary circuit is placed a condenser, which prevents the lamp current entering the induction coil, but allows the induction current in the transmitter circuit to pass without obstruction, and this arrangement

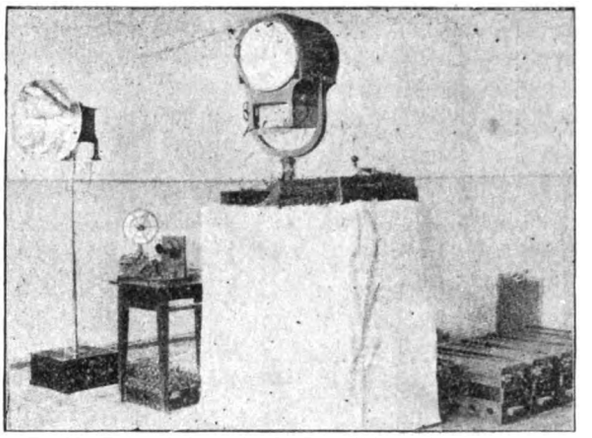

FIG. 16.—Ruhmer's Apparatus for Long-Distance Telephony over a Beam of Light.

has the effect of greatly increasing the sound. By employing a condenser of from three to five microfarads, he compensates for the difference of phase produced by the self-induction in the circuit, thus producing the highest effect in the arc. When Duddell uses the arc for transmitting sound waves, he employs in the shunt circuit to the arc a condenser and receiving telephone. It is advisable to employ as long an arc as possible. It has also been found that the Moore vacuum tube and the various types of mercury arc, such as Arons, Hewitt, and Weintraub, are very suitable for this class of work, as well as the carbon arc; and, where the latter is employed, either cored or treated carbons are advisable.

The theory advanced to account for the phenomena of the speaking arc, is that variations in temperature of the arc are produced by the variations of the current, and the change in the Joule effect produces a corresponding variation in the volume of the conductive gases in the arc. The most successful and most extensive experiments which

FIG. 17.—Ruhmer's Wireless Telephone Receiving Station at Wannsee, Berlin (taken at night).

have been made with the speaking arc are those of Mr. Ernest Ruhmer, of Berlin, Germany, who has employed it in conjunction with his selenium cells for wireless telephony and with remarkable success. In Fig. 16 is shown the apparatus employed by Mr. Ruhmer, with which he has succeeded in transmitting speech over a beam of light 4¼ miles in length.* Mr. Ruhmer's apparatus

* Mr. Ruhmer has recently written the author that he has succeeded in talking over a beam of light a distance of over 10 miles.

Digitized by Google

is shown in the illustrations thrown upon the screen, and in Fig. 17. In his experiments he employed an arc lamp with a flaring arc 6mm. to 10mm. long, using an E.M.F. of 220 volts. The current varied from 4 to 5 amperes at 1 km. to 2 km., 8 to 10 amperes for 3 km. to 4 km, and 12 to 16 amperes for 5 km. to 7 km., and the resistance of his selenium cell was 120,000 ohms in the dark, this falling to 600 ohms in full sunlight. For the transmitting end Mr. Ruhmer employs a carbon

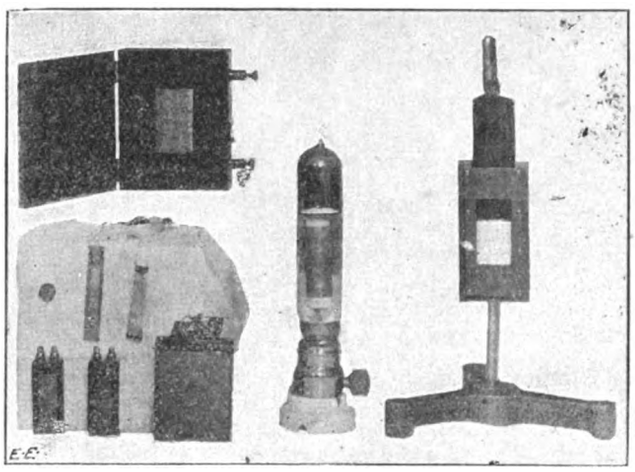

FIG. 18.—Types of Selenium Cells.

transmitter and a battery superimposing waves on the arc light circuit, and the beam of light is reflected to some distant point, where it is received by a parabolic reflector, in the focus of which is placed a selenium cell connected with a battery and a pair of very sensitive telephone receivers. Mr. Ruhmer has conducted extensive experiments both by night and by day, and even during fog and rain on the Wannsee, near Berlin. On the screen you will see an illustration of his apparatus in actual work at night (Fig. 17). Some time ago I suggested to Mr. Ruhmer the employment of Edison's tasimeter, the extraordinary sensitiveness of which is well known. He informed me that he had tried this, but had found it too "lazy," and stated that he has secured most promising results by the employment of the thermopile, and with this he expects to be able to transmit sound over many miles. Mr. Ruhmer is about to commence extensive experiments under the direction of the German Government in connection with the Imperial fleet in the Baltic Sea. Mr. Ruhmer has also suggested the employment of his photographophone, which I shall describe later, as a means of recording messages received at a distance.

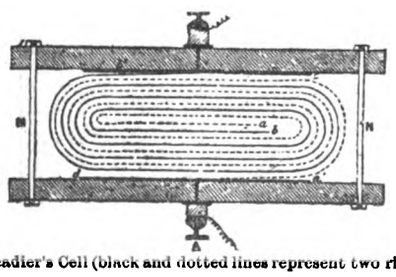

FIG. 19.—Mercadier's Cell (black and dotted lines represent two ribbons of brass).

Doubtless many present remember the interesting experiments made by Mr. Hayes at the electrical exhibition held in Madison-square Garden in May, 1899, in which music was transmitted over a beam of light. At one end of the garden was placed a telephone, before which a cornet was played, causing waves of current in the telephone circuit to be superimposed upon those in a neighbouring arc light circuit. The light rays from this arc lamp were reflected across the garden, where they were received in a parabolic reflector in the focus of which was a glass bulb containing filaments of carbon. This bulb was connected to a pair of ordinary phonograph listening tubes. The varying light which fell upon the carbon caused variations of temperature inside of the glass bulb which produced the original sounds in the listener's ear. A bulb simply coated with lampblack and containing nothing but air would answer the purpose just as well. Selenium cells may vary in resistance from 2,000 to 500,000 ohms or more in the dark; and certain cells may be five to twenty times as good conductors of electricity in light as in the dark; and in the case of other cells, notably that of the Fritts cell, which I have here this evening, and that of the Ruhmer cell used in his Wannsee experiments, will have 200 times the conductivity in light that it has in the darkness; and the ratio may be even higher. They are usually made by winding carefully two separate lengths of wire, either of copper, brass, German silver, or platinum, equidistant throughout their entire length upon such substances as slate, glass, mica, or porcelain. The selenium is then spread thinly over the wires, forming an insulation between the two windings. This form of cell was invented by Mr. Shelford Bidwell, F.R.S. No small amount of skill is necessary to wind these fine wires evenly and equidistant, and to cover successfully these wires with the selenium coating. One way of coating frequently employed is to warm the cell on a metal plate or sand bath heated by a Bunsen burner. When the stick of selenium laid on the plate shows evidence of melting, which takes place at about 120deg. C., it is drawn slowly over the wires, coating the same thinly and evenly. A steel spatula or a strip of mica can be used with advantage. Or the strip of material on which the wires have been wound would be laid upon a brass plate covered by a strip of this

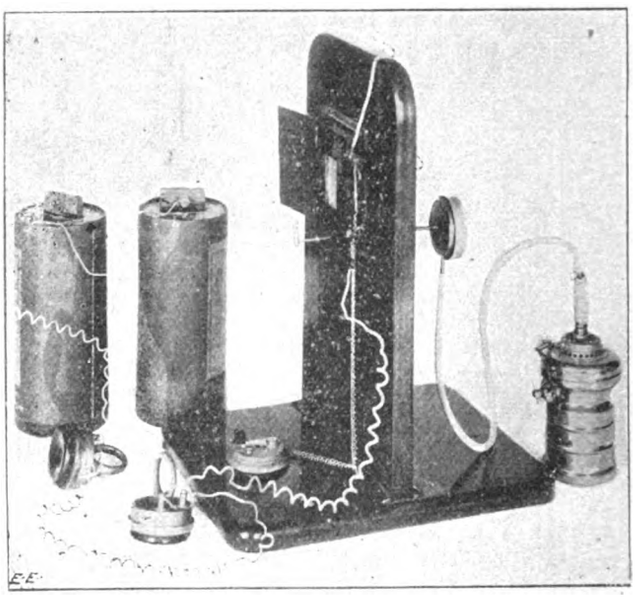

FIG. 20.—Manometric Acetylene Flame Transmitter, with Solenium Cell, etc. (a battery of about 24 volts employed).

mica, this being placed upon a tripod with a Bunsen burner underneath. Powdered vitreous selenium may thus be spread evenly over the wires, and the selenium will shortly melt, and where the portions of it crystallise, forming hard lumps, it will be necessary to continue the heating until these disappear. Then the selenium may be spread uniformly with a piece of steel, or, better still, a strip of mica, care being taken to cover up the edges. Mr. Bidwell states that the temperature should be carefully regulated, as when it is too low, hard crystalline lumps will form, and when too high, the surface tension causes the selenium to form in drops, and it is then as difficult to spread as if it were mercury. The proper temperature should be only just above 217deg. C., and then the selenium is in a plastic semi-fluid condition, and can be easily manipulated. When a satisfactory surface is secured the cell should be placed upon a thick copper plate to cool quickly, when the selenium becomes black and lustrous. The Bunsen flame should then be turned down to give a temperature of about 120deg., and the cell is then placed upon the hot plate, and shortly the whole surface of these turns to a dull grey colour. The temperature is then cautiously raised until signs of melting begin to appear, generally near one of the edges. When this occurs, the burner is instantly with drawn and the flame lowered. The dark spot recrystal-

Digitized by Google

lises in the course of a few seconds, and the burner is then replaced and left for four or five hours, during which time the Se should be only a few degrees below the melting point. The coil should then be gradually cooled by lowering the flame gradually for an hour. This process of long heating and slow cooling is generally spoken of as "annealing."

In Fig. 18 is shown an illustration of a number of types of selenium cells, including the Bidwell, Ruhmer, Giltay, Webb, Clausen and Bronck, Mercadier, and Fritts, which I have brought with me for your consideration. The two cells to the extreme right and left are modifications of Mr. Shelford Bidwell's cells, the original form of which consisted of two fine copper wires wound side by side on oblong strips of mica with melted selenium spread over the surface, the one to the left being manufactured by Ernest Ruhmer, of Berlin, and by Messrs. Clausen and Bronck, which consists of copper wire wound on slate. The one to the right is manufactured by Mr. J. W. Giltay, of Delft, Holland, and consists of platinum wire wound on slate and covered with selenium. The four tiny shells shown against the white background are made by Mr. Hartwell W. Webb, of New York City, and consist of German-silver wire wound on slate. The cell to the right is placed in a sealed flat glass tube. The two lower Webb cells are encased in ebonite. The small round cell is a tiny Mercadier cell made by Mr. Webb. The method of making the Mercadier cell is to use two narrow ribbons of sheet brass or foil, separated by a ribbon of parchment paper rolled up like a spiral spring. This is held between wooden clamps, one surface being ground and polished off smoothly, and a thin layer of selenium being spread over it. An excellent idea of this cell may be had by noting Fig. 19, which shows the standard form. In the centre of the picture is shown a cell by Mr. C. E. Fritts, of New York City, for which I am indebted to my friend Prof. Geo. F. Barker. In the Fritts cell a very thin layer of selenium from one one-thousandth to one five-thousandth of an inch in thickness is spread upon a plate of metal—generally zinc or brass. The selenium and metal plate form a chemical combination sufficient at least to cause the selenium to adhere and make good electrical connection. The upper surface of the selenium is then covered by a transparent conductor of electricity—preferably a thin film of gold leaf. Platinum or silver may also be employed. Thus, the two surfaces of the selenium are covered by a metal, and are connected to the two ends of the circuit. The upper or gold leaf surface, however, permits the light to pass through and affect the resistance of the selenium beneath. The tall cell in the lamp socket shown is the latest form of Mr. Ruhmer's cell, and this type represents, I believe, the most important development which has been made in the selenium cell, and it has now become most stable, and responds most rapidly to variations in illumination. He employs two copper wires, wound spirally side by side around a cylinder of porcelain, which, after the wires have been covered with selenium, is placed inside of a globe, from which the air is exhausted, and it is mounted with a butt similar to an Edison incandescent lamp, and resembles a candelabra lamp. This makes a most convenient method of handling the cell, and by keeping it from the air, the disadvantages inherent in all cells heretofore have been very largely done away with. Another form of Ruhmer cell consists of two fine platinum wires wound on a glass cylinder 1¼in. long and ¾in. in diameter; the wires, which are $\frac{1}{32}$in. apart, are coated with selenium.

Selenium cells are very susceptible to moisture, and it is largely this taking up of moisture which produces the electrolytic effect in the cell, enabling one to connect it with a galvanometer and produce a current by merely focussing the light upon the cell. This phenomenon gave rise to the designation of the photo-electric cell. Those who have worked with selenium cells know that heretofore they have been most unreliable, varying their resistances from time to time enormously; and in the case where copper wires are employed, there is a selenide of copper formed, which often renders the cells inoperative in a comparatively short time. To some extent, the cells made originally have been protected by covering them with mica or lacquer or varnish, but placing them in an exhausted receptacle and mounting them in the manner devised by Mr. Ruhmer is, it seems to the writer, a most important step in the commercial development of the selenium cell. Prof. Bell has made a number of types of selenium cells, his standard form consisting of alternate discs of brass and mica, with the mica discs slightly smaller than the brass, forming a recess for holding the selenium, which is spread over the surface. All the evenly-matched discs are connected to one end of the circuit, and all the odd discs to the other end. The cylindrical form of the cell enables it to be acted upon from all directions when placed lengthwise in the focus of a parabolic reflector. This is also of great advantage in the Ruhmer type of cell. Selenium cells possess the remarkable property of recovering the original resistances upon the removal of the source of light.

(To be continued.)

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTROLYSIS OF ZINC.

SIR,—My attention has been drawn to certain remarks made by Mr. A. Philip in a book on "The Electro-plating and Electro-refining of Metals," which seem likely to convey the wrong impression that the idea of utilising zinc dust for regenerating zinc electrolytes originated with him. Permit me to say that this is not the fact, and also to point out that Mr. Philip omits to mention that at the time he refers to he was employed by the company with which I was associated.—Yours, etc.,

SHERARD COWPER-COLES.

WIRELESS FIRE-ALARMS.

As stated in our last issue, we then wished to conclude all correspondence on the above subject until Mr. Guarini could give actual results from trials on a commercial scale. Since then we have received from him a very long letter, which we do not see our way to print. In the first part of it he complains of the treatment we have accorded to him, and accuses us of showing undue preference to Mr. Oatway. In reply to Mr. Oatway he makes statements which can well be condensed as follows. With regard to the interference, he thinks no further answer is required until further trials have been made in London, which will cover his critics with confusion. With respect to the fire detector which is to set in motion the wireless signalling apparatus, Mr. Guarini claims the right to use the best fire-detecting apparatus on the market. With respect to Mr. Oatway's remarks as to the Postmaster-General, Mr. Guarini thinks his consent will easily be obtained after the trials have been made, as the wireless system will be less likely to interfere with the telegraph wires than the fire-alarm system would with wires. He quotes an Italian expert to the effect that having individual wires to each house to be protected makes a fire-alarm system very complicated. He also thinks that Mr. Oatway has under-estimated the cost of providing lines between the fire brigade station and subscribers. This cost with underground wires Mr. Guarini estimates at from £20 to £40 per line. If the firemen's objection to depending on Morse code signals is maintained, Mr. Guarini would employ a professional telegraphist at each station at the cost of the firms protected. In conclusion, Mr. Guarini bids us "au revoir" and not "adieu." We await, with him, the practical trial of wireless fire-alarms, and much regret that the exigencies of our space prevent us from reproducing his letter in full.—ED. *E. E.*

PRODUCTION IN QUANTITY.

At the present time, when everyone in business is anxiously awaiting statements from the Government as to their new fiscal policy, a few words on the question of manufacturing articles in large quantities will be of interest. It is intimately connected with the dumping of foreign manufactured goods on our markets. The argument, which can be supported by a number of facts, is that certain of our foreign competitors organise their works so that they can produce at exceedingly cheap rates large quantities of standard articles. They then supply their home markets at a profit, and interfere with the legitimate development of English manufactories by dumping the surplus in this country at, or even below, cost price. The same method of procedure cannot be adopted in England, because our manufacturers are hampered by the import duties when sending goods into the very countries in which their rivals have their works. Quite apart, however, from these questions of Imperial policy is that of the internal organisation of the electrical industry in this country. It is a regrettable fact that the individuality of the English engineer, of which we have every reason to be proud, has in the electrical industry seriously hampered the manufacturer. For instance, at the present time, when the electric supply undertakings, whether municipal or company, are beginning to realise the fruits of their development work in electric power supply, the demand for electric motors is very great. Manufacturers who have adopted electrical driving find that it is economical, and that it enables them to organise in an entirely new way the work in their factories. They accordingly look for cheap motors, and most frequently demand quick deliveries. The essence of quick delivery is that the manufacturer should be able to manufacture in quantity and supply from stock, which only too frequently cannot be done. Taking small motors for instance, it is almost an even chance as to whether the supply voltage will be 200, 220, or 230, while voltages of 210, 240, and 250 are also to be found. With larger motors working across the outers of a three-wire system, the supply voltage will be equally varied by multiplying the above figures by 2. As a consequence, if the manufacturer is to be able to supply from stock electric motors, he must stock them with a comparatively large number of voltages. This as a rule it does not pay him to do, and we find instead that only a few machines are stocked in a completed state, and that those for other voltages have to be wound after the order is given. In other words, manufacturers are compelled by the conditions prevailing in this country to stock motor frames rather than completed motors. The same applies to lamps and other accessories used in connection with the supply of electricity as a means of providing light, heat, and power. Matters become even worse when alternate-current systems are concerned, as in that case the frequency is varied quite as widely as the voltage. It is to be hoped that the Engineering Standards Committee, the electrical section of which is presided over by Sir William Preece, will be able to recommend standard voltages and frequencies, which will in time reduce the confusion which now exists, which hampers our manufacturers and increases cost of electrical accessories. This committee has circulated amongst manufacturers and other prominent electrical engineers a number of proposals as to standardisation. In due time, after replies have been received as to how far these standards are suitable, the committee will issue its recommendations on the subject. It is to the interest of the whole profession that these recommendations should not be as inoperative as have other efforts towards the

Digitized by Google

standardisation of electrical machinery. From the reply given to the deputation from the Engineering Standards Committee by the First Lord of the Treasury last year, we gather that the War Office and the Admiralty are in accord with the committee and prepared to heartily co-operate with its efforts. We are afraid that the same cannot be said for the electrical engineers, whether consulting or resident, who are responsible for the variations of supply voltage, frequency, etc., in our supply systems. Leaving restrospective changes on one side for the moment, it seems to us that the Board of Trade has the power to prevent new works being started which do not conform to the standards soon to be recommended. Up to the present the Board of Trade has, we believe, approved of practically every system of supply submitted to them as required by the provisional orders. We trust that for the good of the industry they will in future not be so lenient, but that consent will be refused unless the voltage of supply and the frequency conform to certain definite standards. If this is done, there is a hope that those older undertakings which find themselves at variance with the standards will be induced to change. The Board of Trade could hardly force this change, but an association of manufacturers could do so by charging by mutual consent a slightly increased price for all accessories which are not to standard. It remains to be seen how far this latter proposition is within the scope of practical politics, but it would conduce to the production of electric accessories in great quantity, and hence to the cheapening and improving of the same.

REVIEWS.

Electricity as Applied to Mining. By ARNOLD LUPTON, G. P. ASPINALL PARR, and HERBERT PERKIN. Crosby Lockwood and Sons.

The ever-increasing use of electricity in mining has led the authors to write a text-book, having for its object the presentation of the main principles of electricity and electrical engineering in such a form that a mining engineer or colliery manager may obtain a sufficient grasp of the subject to enable him to deal with the many questions involving the use of electricity arising in his daily work. The difficulties in achieving this object, without overweighting the book with detail, are very great, and require skilful treatment in order not to confuse a non-electrical reader, and at the same time furnish him with accurate information.

Difficult as the authors' task is, it is none the less difficult for a reader to acquire this knowledge when presented to him in such necessarily abbreviated form, and in the book before us these difficulties are materially added to by reason of the vague and slipshod manner in which fundamental principles are stated—*e.g.*, the authors on p. 8 say, "We shall denote the extreme difference in pressure of any circuit by the term electromotive force (abbreviated to E.M.F.), while that between any two other points, which must necessarily be lower, by the term potential difference (abbreviated to P.D.)" The mining engineer or colliery manager who understands the difference between E.M.F. and P.D. after reading this statement, can hardly require any assistance from the authors. We doubt very much, however, whether anyone would understand the difference from such a statement, and we think a simpler and more easily understood explanation would be, that the E.M.F. of any source of electricity is its voltage on open circuit, as measured by an electrostatic voltmeter; P.D. being simply what the name implies, the difference of potential between any two points in a circuit. Again, we are told "when two or more cells are joined together 'end on' or 'in series' with each other, the arrangement is termed a 'battery.'" This appears to us to be a definition which is scarcely needed, and is barely accurate, the term "battery" in practice being used for any number of cells exceeding one, however connected. Further, on p. 31 we have a statement, "In practice there are two distinct kinds of current . . . one is called alternating current . . . the other continuous." This in a text-book is, we think, likely to give an erroneous idea; the current, *per se*, of course being the same whether alternating or continuous. There are many such ambiguities, particularly in the introductory chapters of the book, but we have indicated sufficient to show what we believe will prove stumbling blocks to many readers.

The subject of electromotors, which, in many cases, is the most important in connection with mining, is dealt with much too briefly, and could, we think, with great advantage be considerably amplified. For instance, in the case of the direct-current motor, practically no information is given on the all-important question of speed regulation or how variations of speed are to be obtained, as is so often required in practice. This same paucity of information is also noticeable in the authors' treatment of polyphase motors. The illustration of the principle of the alternating current motor, given in Fig. 39 and the accompanying description, is clear so far as it goes, but, in our opinion, will not enable a reader to understand how the polyphase current provides the equivalent of a rotating field magnet. To many engineers the action of an induction motor, particularly if it has a squirrel-cage armature, and consequently no slip-rings, is uncanny. Here, again, a great deal might be said with advantage on the question of speed regulation.

In dealing with the generation of electricity the authors discuss very briefly the various types of power available. This subject, we consider, should either have been dealt with more briefly or much more fully, depending on the point of view. For instance, on the one hand, most mining engineers would be quite competent to decide the question of the best power to employ, in which case the greater portion of the information given in Chapter 3, will already be known to them; on the other hand, such engineers are probably not in touch with the latest developments in prime movers as employed in central stations, and space devoted to a more detailed description of such central-station plant would doubtless prove useful. To a slight extent this has been done in connection with steam-turbines. The above remarks apply even more forcibly to the authors' treatment of switchgear. Every electrical engineer knows the many pitfalls in connection with the switching arrangements of even the smallest generating station.

The discussion of the various systems of distribution is fairly complete, and provides much useful information. We do not agree, however, with the authors that the size of a cable for transmitting electricity is chiefly determined by the number of amperes it can carry, without the temperature being raised to a dangerous amount. Neither can we agree that Table I. proves this. It is well known that a current density of 1,000 amperes per square inch in transmission cables is perfectly safe, but in practice this density is not admissible, because in the case of lighting the drop in the cable is fixed, and in the case of power the questions of regulation are paramount. These considerations, in practically every case, determine the working density, and this, as is shown in Table I., seldom approaches 800 amperes per square inch.

The illustrations and descriptions of electrically-driven machinery as used in mining are very clear, and will doubtless prove of great assistance to those employed in such work, and should, we think, lead to a much more extensive use of similar plant in this country.

In conclusion, we would like to point out to the authors, the apparent irrelevancy of the titles of some of the chapters, and would particularly instance Chapter 6; also the tiresome repetition of the most elementary facts—*e.g.*, on p. 143 in the section devoted to the "Reasons for Economy of High Tension." In less than 10 lines we have four equivalent statements that $E \times C$ = watts = power, and a little further on five lines of print are devoted to showing that, in a line working at 600 volts with a 5 per cent. drop the pressure at the far end is 570.

The book is well printed and illustrated, and if in a new

Digitized by Google

edition the defects, such as we have pointed out, are rectified, will fill a distinct gap in our technical literature.

G. W. G.

THE BRITISH ASSOCIATION.

The following is the provisional list of papers to be read before Section A (physics and mathematics) of the British Association at the forthcoming Southport meeting: "On the Treatment of the Thermo-Dynamics of Irreversible Processes," by Mr. J. Swinburne; "Granular Structure in Solids," by Mr. G. Beilby; "Explosive Pressure and Rate of Combustion of Cordite," by Mr. J. E. Petavel; "Simultaneous Solar and Terrestrial Phenomena," by Sir N. Lockyer; discussion on "The Nature of the Emanations from Radioactive Substances," opened by Prof. Rutherford—Profs. J. J. Thomson, Dewar, Soddy, and Armstrong will take part; "Report of Electrical Standards Committee," by Dr. R. T. Glazebrook; "On the Use of Vectorial Methods," by Prof. Henrici, with discussion; "On the Use of Condensers as Multipliers to Extend the Range of a Multicellular Voltmeter," by Prof. Marchant; "On Design and Working of Ballistic Galvanometers," by Mr. P. H. Powell. Meteorology will be strongly represented owing to the meeting of the International Meteorological Committee taking place at Southport at same time.

Following are the provisional arrangements for Section F (economic science and statistics): Thursday, Sept. 10—presidential address of Mr. E. W. Brabrook, chief registrar of Friendly Societies; Friday, Sept. 11—discussion on "The Wealth of the Country and what should be done with it," opened by Sir Robert Giffen. Monday, Sept. 14—papers and discussion on the economic aspects of the fiscal controversy, as follows: "Modern Economics and Free Trade," by Dr. E. Cannan; "Failures to Attain the Ideals of Free Traders," by Prof. W. Cunningham; "Statistical Methods and the Fiscal Controversy," by Mr. A L. Bowley; "Comparative Statistics of our Trade with our Colonies, U.S.A., and the Protected Countries of Europe," by Mr. B. Etlinger; and probably papers on "History of Retaliation," "History of Commercial Relations with Canada," and "Statistics on Production." Thursday—final report of committee on "The Economic Effect of Legislation Regulating Women's Labour"; "Physical Deterioration and the Poverty Line," by Mrs. Bosanquet. The following other papers will probably also be read before this section: "Depreciation and Sinking Funds in Municipal Undertakings," by Mr. S. H. Turner; "The Growth of Rates," by Dr. Ginsburg; also a paper on "Garden Cities." It is not quite settled yet on which day the papers on the fiscal controversy will be taken, but, so far as can be stated at present, Monday, Sept. 14, will probably be devoted to this subject. The discussion of social questions is expected to occupy the following day, Sept. 15, but it is very possible that this order of things may be reversed and the social questions disposed of before the fiscal controversy is entered upon.

The preliminary programme of papers in Section G (engineering) is as follows: "The Problem of Modern Street Traffic," and "An Account of the Manchester Municipal School of Technology," by Lieut.-Colonel Crompton, R.E., C.B.; "Protective Devices for High-Tension Circuits," by Mr. W. B. Woodhouse; "Permanent Set in Cast Iron, due to Small Stresses, and its Bearing on the Design of Piston Rings Springs," by Mr. C. H. Wingfield; "Refuse Destructors and Power Production," by Mr. W. F. Goodrich; "The Rebuilding of Kew Bridge," by Mr. C. A. Brereton; "Parallel Running of Alternators," by Mr. B. Hopkinson; "Balancing of Large Engines," by Prof. J. Perry; "Pendulum Apparatus for Testing Steel as Regards Brittleness," by Captain H. Riall Sankey, R.A.; "A New Form of Mirror Extensometer," by Mr. J. Morrow; "Clutches," by Prof. H. S. Hele Shaw; "Ventilation of Tube Railways," by Mr. J. W. Thomas; "Liquid Fuel," by Mr. A. M. Bell; "The Potable Waters of S.W. Lancashire," by Mr. J. Campbell Brown; "A History of the Discovery of Natural Gas in Sussex," by Mr. R Pearson; "The Manchester and Liverpool Express Railway," by Mr. F. B. Behr; "Aluminium as an Electrical Conductor," by Mr. J. B. C. Kershaw; "The Water Supply of South-West Lancashire," by Mr. J. Parry; "The Tidal Régime in the Mersey" and "Electric Traction," by Mr. J. N. Shoolbred; "A Further Note on Gas-Engine Explosions," by Mr. H. E. Wimperis; "The Single-Phase Repulsion Motor," by Mr. W. Cramp; "Steam Traffic on Common Roads," by Mr. T. Clarkson; "The Rate of Fall of Rain at Seathwaite," by Mr. H. R. Mill; "Smoke Abatement," by Mr. W. G. Popplewell; "Illustrations of Graphical Analysis," by Mr. J. Harrison; also reports of the Small Screw Gauge Committee and the Road Traction Committee. In connection with Section G, visits have been arranged to the following, among other, places of engineering interest: the Manchester Municipal School of Technology; the works of the British Westinghouse Electric and Manufacturing Company, Trafford Park; ss. "Lucania," Liverpool; the British Insulated Wire Company's Works, Prescot; the L. and Y. Railway Company's works, Horwich; the Wigan Deep Coal Pit.

In Section L, devoted to educational science, it is proposed to devote two days (Sept. 10 and 11) to a discussion on "School Curricula," based on a series of short papers. Introductory papers have been promised by Miss Burstall and Messrs. M. E. Sadler, J. L. Paton, W. L. Fletcher (Liverpool Institute), John Adams, T. E. Page, and others. A joint meeting with the Geographical Section will be held to discuss the "Teaching of Geography." In addition to the above subjects, there will also be discussions on the reports of committees on the conditions of health essential to the carrying on of the work of instruction in schools; the teaching of natural science in elementary schools; the influence exercised by universities and examining bodies on secondary school curricula, and also of the schools on university requirements; the teaching of botany in schools.

BRADFORD CITY TRAMWAYS AND ELECTRIC TRACTION.*

BY J. H. COX, M.I.C.E., CITY SURVEYOR, BRADFORD.

During the last few years the subject of electric traction has been dealt with most exhaustively by numerous tramway engineers, and this short paper is, therefore, merely intended as a brief general statement of the present position of electric traction in Bradford. The total route length of tramways worked by the Bradford Corporation is 43 miles 513 yards, mostly double track, equal to nearly 75 miles of single track. Of the above route length, 5 miles 1,672 yards is outside the city boundary, and of this 1 mile 815 yards belongs to the Shipley District Council.

Shipley Tramways — Terms of Lease. — The tramway belonging to the Shipley District Council extends from the city boundary at Frizinghall to Moorhead-lane, at Saltaire, and is leased to the Bradford Corporation on the following terms, which were fixed by arbitration—viz.: (1) Lease to be for a period of 30 years. (2) The Bradford Corporation pay the Shipley Council interest and sinking fund charges at the rate of £5. 14s. 6d. per cent. per annum for 30 years from May 17, 1903, on £27,614, the sum expended by them on the construction of the tramway. (3) The Bradford Corporation pay Shipley Council interest and sinking fund at the rate of £4. 10s. 3d. per cent. per annum on the capital sum of £12,642 expended by them on street improvements. (4) Shipley Council are to supply sufficient electrical energy for the proper working of the tramways at 1¾d. per Board of Trade unit, measured at the station, but the price chargeable is subject to revision every five years. (5) The Shipley Council to maintain the tramway track, cables, feeders, and posts; but the overhead equipment is to be maintained by the Corporation. The Corporation have also to contribute the sum of £100 per annum per mile of double track towards the cost of maintenance, and in consideration of this payment they are to be relieved of all

* Paper read before the Congress of the Sanitary Institute at Bradford.

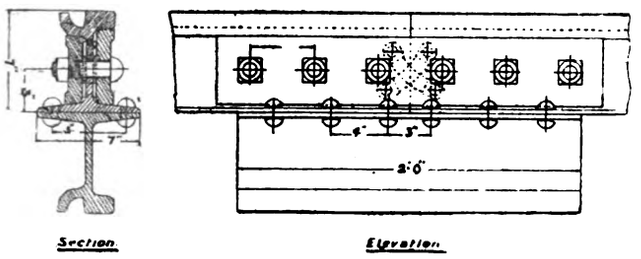
Digitized by Google

liability in respect of any accident arising from the defective condition of the tramway. (6) Cost of arbitration to be borne equally by both parties.

Overhead Equipment.—The overhead equipment is of the usual standard form, and centre pole, side bracket, and span wire construction have been used to meet the varying conditions of the several tramway routes. Flexible suspension fittings have been fixed to all the bracket arms. Experience has shown that it is not advisable to erect centre poles, except in streets where the carriageway is at least 45ft. in width. It will be interesting to compare the working of the overhead system with that of the underground conduit system, as adopted by the London County Council, and also with the Lorain surface-contact method, as laid on a portion of the Wolverhampton tramways. At present the advantages as regards cost of construction and working appear to be in favour of the more popular system.

Rails.—The section of girder rails now used in Bradford is supplied by Messrs. Walter Scott and Co., Limited, Leeds Steelworks, No. 15 in their list. It is 7in. deep, with a groove 1⅛in. in width and 1⅛in. in depth. The rails are rolled mainly in lengths of 45ft., and weigh 102lb. to the yard. The chemical constituents of the rail are as follows: carbon, ·4 to ·55 per cent.; silicon, traces; sulphur, not more than ·06 per cent.; phosphorus, average ·08 per cent.; manganese, ·7 to 1·10 per cent. The specification states that the tensile stress must be 40 to 44 tons per square inch, with an elongation of not less than 15 per cent on a length of 8in., and a contraction of sectional area of not less than 30 per cent.

Rail Joints.—The rails are jointed with steel fishplates weighing 73½lb. per pair. Latterly, Cooper and Howard Smith's patent anchor joints have been largely used in



Rail Joint, Bradford City Tramways.

addition to the fishplates. At present these joints appear to be answering satisfactorily, but they have not been in use sufficiently long to enable one to give a definite opinion

Curved Rails—Manganese Steel.—One or two quick radius curves have been constructed with manganese steel, cast in 12ft. lengths by Messrs. Hadfield's Steelfoundry Company, Limited, of Sheffield. They have only been in use about four months, and up to the present they have justified their adoption.

Points.—The points used on the Bradford lines are 9ft. in length, made of patent manganese steel, with tongues 4ft. 6in. in length; some are straight, and others are made to a radius of 100ft The core hollows in points and crossings are filled with concrete before being laid.

Bonding.—The electrical bonding of the rails is done with short Chicago crown T-bonds, 4in. centre to centre, fixed under the fishplates which act as a protection to them.

Special Lay-outs.—In May, 1902, certain portions of the curves and junctions into Bridge-street, from Tyrrel-street, Market-street, and Leeds-road, were specially made by Messrs. Hadfield's Steelfoundry Company, Limited, of Sheffield, with their patent manganese steel rails, points, and crossings, and they seem to be answering very well, though up to the present they have not been subjected to any great amount of traffic.

Wear and Life of Rails.—Experience at Sheffield tends to show that the wear of rails is greatest on the down tracks; very probably this is accounted for by the greater use of the brakes, especially the slipper brakes, which the Board of Trade require to be used on the downward journey whenever the gradient is 1 in 15, or steeper. Experience in Bradford shows slightly more wear on the downward tracks, but greater damage is done to the track generally on the upward journey. On the comparatively level portions of tramway the damage to the track is mainly due to the speed at which the electric cars run. Under the heaviest traffic, in Bradford, it is expected that a life of eight to ten years will be obtained on straight track, and about three years on curves. Under the lightest traffic 12 to 15 years' life is anticipated on the straight lines, and about five years on curves.

Paving.—In Bradford the tramway tracks are paved with 3in. by 6in. granite setts, except in a few streets near the centre of the city, where Australian hardwood blocks have been used. The granite setts are obtained chiefly from Leicestershire, Wales, Scotland, and Norway, the harder setts being reserved for the level roads and the softer setts for the steeper gradients, which in Bradford are very numerous. Concrete foundations, composed of broken stone and Portland cement in the proportion of 6 to 1, are laid for the paving of all tramway tracks. The wood blocks used for paving tramway tracks are 3in. by 9in. and 5in. deep. They are laid on a concrete foundation which is floated to a smooth surface so as to admit of the blocks being laid directly on the concrete. They are first dipped to a depth of 3in. in hot pitch and set on the smooth concrete surface with at least ⅛in. joint between every course, and also endwise between every block. The space between the ends of the blocks laid between the rails is slightly greater than those at the side, but a space of about 1in. is also left against the kerb on each side of the road for expansion of the blocks, and filled in with pitch, which will compress when expansion of the wood takes place. Some difficulty has been experienced by the rising of the blocks adjoining the tramrails, which appears to be due to water getting into the spaces formed between the end block and the steel rails. To avoid this difficulty, it is proposed to shape the end wood blocks to fit into the web of the rail, and it is hoped that the adoption of this course will more effectually keep out water and prevent any further lifting of those blocks which adjoin the rail.

Speed.—Several months ago an application was made by the Tramways Committee of the Bradford Corporation to the Board of Trade for sanction to run at greater speeds than previously allowed on the Bradford tramways, in consequence of which Major Pringle inspected all the lines in April last, and recommended that regulation No. 6, which limited the maximum speed to nine miles an hour, should be revised and the speed increased to 12 miles. In narrow roads the speed is limited to nine miles an hour; on very steep roads four to six miles; and through facing points, whether fixed or movable, and on quick curves, four miles an hour. There is no doubt that the quicker service and extra speed attained by electric cars cause considerably more wear and damage to the tramway tracks than formerly, but the requirements of the public to-day call for more rapid locomotion than was possible in the days of horse and steam traction. Electric tramways have now become serious competitors with railways for urban and interurban traffic, and railway companies will have to depend more on their long-distance traffic for their revenue in future. The railway companies in the West Riding of Yorkshire, as in other populous districts, have been seriously affected by the great increase in electric tramway traffic during the last few years, and to all appearances it is likely to increase still more rapidly than ever.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the

Digitized by Google

author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

615. Information is required as to the best method of automatic signalling for electric tramways. The system must be equally applicable for use by day or night. Preference would be given to a method by which the current supply to the car it is desired to stop is cut off entirely, so that the car can no longer proceed, and is not merely detained by signals which might or might not be regarded by the driver.—A. G.

616. I have four dynamos, shunt-wound two-brush type, each giving an output of 65 volts 300 amperes. What minimum alterations in windings are necessary to give 120 volts. Would compounding the fields be satisfactory? Give sketches, calculating formula, etc.—H. W.

ANSWERS.

Question No. 607.—What is the best way to doctor small accumulators for electric ignition which have been over-discharged and become badly sulphated?

Best Answer to No. 607 (*awarded* 10*s.*).—Small accumulators which have been badly treated are likely to have more defects than sulphating. Generally the plates are buckled and the paste is loose in places, while some has fallen out. If the paste accumulated at the bottom of the cell is a light brown in colour and extremely fine (not granular), it is likely that the acid is too weak. Many motorists put the accumulators in such a position and pack them so carelessly that acid is spilled at every turn. According to directions water is added, with the result that the acid is diluted in a way never intended by the makers, and immediately sulphating sets in. This is common in celluloid motor-cycle accumulators. As to remedy, add to each cell of, say, 25 ampere-hour size as much *pure* caustic soda as will lie on the surface of a threepenny piece. Charge fully till each cell shows 2·5 volts. Now discharge for, say, an hour and charge up again. Continue this and sulphate will gradually disappear. If the sulphate has taken the form of beads, or looks like a fungoid growth, it will be necessary to scrape the plates carefully. If the cells are vulcanite with pitch tops, place in boiling water for a little time, and the pitch becoming soft the top may be easily taken off with the plates. Wash plates well, and using a piece of window glass or thin hardwood—*not a knife*—gently rub off the sulphate. Wash again, and replace, using a soldering bolt to seal up the cells. If cells are celluloid, paint the joints at the top with "acetone" till soft. In a short time the top may be taken off. The scraping should then be done and plates replaced To cement the tops again, dissolve some celluloid cuttings in acetone till syrupy fluid is formed. This makes a grand cement for celluloid. Clean Kodak films do well if no other celluloid is available.

It has been the writer's experience with motorcar ignition accumulators that where sulphating has set in badly, the paste will soon begin to fall out, especially if vibration is bad. It is a good plan, therefore, when plates are out to stuff the space between them very loosely with spun glass This is now readily obtainable, and though adding slightly to resistance of cell, is perfectly satisfactory for ignition purposes. Another plan is to take dry silicate of soda and drop in between the plates *very loosely* till the level of the plates is reached. Fill up with acid as usual. This forms a jelly "network," and traps powdered paste and supports any paste nodules that tend to fall out. It is preferable to the "solid" jelly sometimes used, as the resistance is not so high.

It might not be out of place to give the following rules for the care of ignition cells: (1) Do not use below 3½ volts for two cells. (2) Do not "overcharge"; it hardens the paste. (3) Keep the specific gravity of acid constant. (4) Protect from vibration by lining cell box with cloth or felt, using three or four layers at the bottom. (5) Never "flash" the terminals to ascertain charge; it may take 20 miles off the running, and shorten the life of cells. (6) Do not leave trembler of coil vibrating any length of time when testing; many high-speed coils take 10 amperes on free circuit, and would soon buckle plates. (7) If cells are not used for some time, say in winter, charge up once a month, or they will sulphate.—POLYPHASE.

Answer to No. 607 (*awarded* 5*s.*).—The old proverb, "That prevention is better than cure," should never be lost sight of when dealing with accumulators, especially small ones, otherwise ruination to the accumulators will be the result. The case stated in the question bears testimony to the above quotation, for it is certainly very much better to prevent sulphating than to cure it, and the prevention is a simple matter and easily performed, while the cure is rather a long and tedious operation. When sulphating has set in, it is a difficult matter to thoroughly cure it. In several bad cases of sulphating which have come under the writer's notice, the final result was a disintegration of the plates, and consequent ruination of the accumulators. This, however, could have been prevented with a little extra attention to the cells.

The term sulphating is applied to the formation of a sulphate of lead on the negative plates caused by over-discharging the cell. The sulphate formed is white in colour, hard, and insoluble in the acid solution. It can be removed by a process of continual charging at a small current. But even this in bad cases is not a complete cure, for if the plates be examined, they will be found to have become rotten. In the case under consideration, if the sulphating is of a bad nature, it would be better and more economical in the end to put in new plates instead of trying to preserve the old ones, as these, after the sulphating has been removed, will be in a poor condition, and will need to be replaced in a short time. The writer has, after a number of cases of bad sulphating, arrived at the conclusion that it is better and cheaper to renew the plates at once rather than try to preserve them, as the time they last when in this condition is very short.

The acid used in the cell should under normal conditions have a specific gravity of 1·180, which can be obtained by adding pure concentrated sulphuric acid *slowly* to water, the proportion being about one volume of the former to nine of the latter. The density of the acid in the cell is a good criterion of the condition the cell is in. When charging, care should be taken to see that the current is not too high, otherwise the paste will be forced out of the plates. When fully charged each cell should give about 2·5 volts, so that a four-volt accumulator should give about five volts at its terminals. The density of the acid rises during the charging, and the phenomenon known as "boiling" (due to the rapid liberation of oxygen during the charging, which causes a spraying of the liquid) is an indication that the cell is charged. The normal voltage of a cell in good condition should be two volts, and this gradually falls when the cell is discharged. The discharge should be stopped when the E.M.F. per cell falls to 1·8 volts, as if this is continued sulphating will result. Accumulators should never be left to stand for any length of time without charging, as this also has the effect of causing the plates to become rotten. Even when an accumulator is not used, it should be given a charge at least once a fortnight in order to preserve the plates. By giving a little extra attention to these points, the life of an accumulator will be very much increased.

The condition of the accumulator should always be determined by the reading it gives when a high-resistance voltmeter is connected across its terminals. Under normal conditions this reading should be about two volts per cell. If the reading indicates 1·8 or 1·9 volts per cell, charging should be proceeded with without delay. If a cell is periodically checked with a voltmeter, and the E.M.F. per cell be not allowed to fall below 1·8 volts, sulphating will be of rare occurrence. It is this little periodic checking (which only requires a *few* minutes to be performed) that forms the "prevention" to sulphating, and which the writer strongly advocates to all users of accumulators. If the "prevention" be not followed, the "cure" will be of a rather expensive nature, and will mean the replacing of the plates in a very short time. As "A. J. R.'s" case seems a fairly bad one, and as the accumulators would not be very large, it would be more economical to replace the plates at once, as even if "doctoring" be tried it will mean the replacement of the plates in a short time. When new plates are installed "A. J. R." will do well if he studies the motto quoted at the commencement, and sees that the voltage per cell is never less than 1·8 volts before commencing to charge, and also to give the cells a charge at least once a fortnight if they have to stand for a time without doing any work.—A. D.

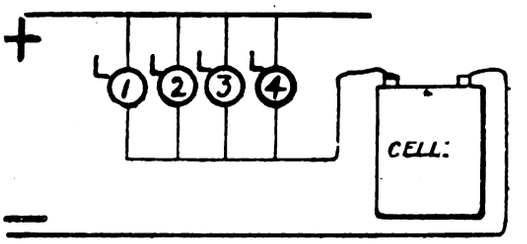
Answer to No. 607 (*awarded* 5*s.*).—Having had long experience with accumulators, the best advice I can give in this case is to pour away the liquid in the cell as received, because there is no knowing what it really is, owing to the various amateurish ideas to which these cells are subject. I have had cells brought to me half full, and in this case probably the acid is much too strong, and I have also had them come with water and practically no acid. Therefore, I advise a fresh start with cold acid solution of specific gravity 1,200, which is the proper strength for the cell; but before putting it in, the cell should be thoroughly washed out at least twice with clean cold tap water and turned bottom up to let any solid particles fall out if possible. The acid solution of 1,200 specific gravity is made by taking about 75 measures of clean cold water and adding to it gradually whilst stirring thoroughly about 25 measures of the best brimstone sulphuric acid (common oil of vitriol is not pure enough). This mixture will be very hot, and must be allowed to cool before it is put into the cell. As soon as it is cool, its specific gravity should be ascertained by a hydrometer. If the hydrometer shows more than 1,200deg, add a little water, but if it shows less, then add a little more acid, and stir well in either case. All being ready, the cell may now be put on to the dynamo as usual and charged, but the more slowly this can be done the better—*i.e.*, use a small charging current. Let the cell give off gas freely for three or four hours, but do not let it get hot. The cell must now be disconnected from the dynamo and discharged at a low rate until its E.M.F. falls to 1·95 volts, when it must be again charged full up as before. It must not be allowed to stand discharged for a single hour. It will most likely be restored to good condition by being charged and discharged in this way twice, or at all events the third time will suffice. To make the cell thoroughly satisfactory, the electrolyte should be poured away and fresh put in as before. When a cell is badly sulphated, both the positive and negative plate are affected. Charging desulphates the grey plate and discharging desulphates the brown plate, but the process is necessarily slow. To prevent sulphating in a good cell, the best plan is never to let it stand empty or half discharged. If the cell will not be wanted for some time, let it be thoroughly charged, then empty out the electrolyte and fill the cell with clean cold water. When the cell is wanted again empty out the water, put in the electrolyte, and charge fully at once, but, of course, with a moderate current.

The following directions were given some years ago for making an electrolyte to prevent and cure sulphating, but I do not consider it better than the above method, and the solution is some trouble to make—viz.: "Add 12 fluid ounces of sulphuric acid to a quart of saturated solution of ordinary washing soda, while stirring well and pouring gently. Add one part of this mixture to 19 of cold water, and then add five fluid ounces of sulphuric acid. This will give a solution of specific gravity 1,200deg."

It remains for me to add that ordinary sulphate of lead is soluble in pure brimstone sulphuric acid, and therefore, provided that the material of the cell itself would not be injured by the acid, a good deal of the sulphate might be dissolved off the plates rapidly by pouring the concentrated acid in, and allowing it to stand for a few hours. This plan could, however, not be recommended in all cases, and the sulphate is not soluble to any great extent in the acid. F. G. A.

Answer to No. 607 (*awarded* 5*s.*).—As a rule, small batteries used for electric ignition get badly treated. The person using the motorcar knows generally nothing about batteries, and often starts on a long journey without seeing that the cells are fully charged, and consequently has to over-discharge them in order to reach his destination. This bad treatment soon causes the plates to be badly sulphated and buckled. To bring them into good condition again is a question of time. I should first carefully examine the plates, and if the sulphating was very bad and the scale in some places bridging across the plates, I should take the battery to pieces and thoroughly clean it. Lift the plates out and at once immerse the negative plates in water, for if they are exposed to the air they will get hot, and on getting the battery together again they will be found to blister. Scrape the plates with a wooden scraper to get as much of the scale off as possible, wash thoroughly, and reassemble the battery together. Avoid having the strength of the acid solution high, for if it is above 1·700 specific gravity, the plates will be sure to be sulphated again. Now start charging at half the maximum rate for a prolonged period. This will gradually reduce the unhealthy sulphate to the healthy form, and finally charge the plates by conversion of the $PbSO_4$ to PbO_2. The white sulphate will be seen to fall off in scales, and if any sticks across the plates, it should be pushed down with a piece of wood. A plate that is sulphated has a very much smaller useful surface than a plate in good condition. If the ordinary amount of current be used to charge a plate badly sulphated, then only part of that current is doing useful work—*i.e.*, changing the chemical composition of the plates—the rest simply being wasted in splitting up the electrolyte. After the battery has been charged and discharged carefully a few times, the plates should assume a healthy colour.

Sir David Salomons recommends doctoring battery solution with sodium sulphate. I have tried it, but not with any very marked beneficial results. "A. J. R." may be more fortunate, however, and at any rate no harm is done. Dissolve 1oz. of sodium sulphate in 5oz. of water, and add this amount for each gallon of electrolyte. It should be added at the conclusion of the charging. Effervescence usually takes place, due to carbonic acid gas being given off, but this is of no consequence. Motorcar cells are usually supplied in vulcanite cases, sealed up, and very little idea can be obtained of the condition of the plates from the voltage and specific gravity reading. The plates may be badly sulphated and yet the cells give a good voltage. There is nothing like having the plates always visible, as the user of the battery can always tell by the colour of the plates when anything is wrong. I have seen battery cases apparently made of celluloid. They were strong, acid tight, and transparent.



The arrangement I have generally used for charging small batteries from continuous-current lighting mains is as shown in the accompanying diagram. L_1, L_2, L_3, L_4 are lampholders wired in parallel, and the current is varied by inserting more or fewer lamps in. The voltage of the mains is immaterial, providing, of course, it is not less than that of the battery. Lamps of the same voltage as the mains should be used. Batteries in vulcanite cases, sealed up, are provided, with little indiarubber bags fitted over the ventholes, which are blown up when the electrolyte starts gassing, thus indicating that charging is completed.—W. A T.

Question No. 608.—An engine I have charge of is constantly breaking one or the other of the cross-head bolts. Can this be remedied? The cross-head has a double guide similar to the marine type. When the keep is screwed up tight there is about ¼in. clearance between cross-head and keep. After working a few days the bolts get loose and then break.

Best Answer to No. 608 (*awarded* 10*s.*).—Presumably, from the question, it is not a case of the bolts being insufficient in area to stand the load, but it is some other cause which ultimately leads to their fracture. The question states, "the bolts get loose and then break." It would seem as if the real cause of the breakage lies in the fact that the bolts do get loose, and the attendant result—viz., hammering at the cross-head pin—is sufficient to break them. This may very possibly be the case. Bolts designed for a steady load will not stand a load of the same magnitude applied as a shock.

Why do the bolts get loose? It naturally suggests the question, Are the nuts on the bolts securely locked to prevent their gradual slacking back owing to the vibration of the moving parts? If the bolts are not already locked

Digitized by Google

they should be; and if they are, a careful examination should be made to see if the locking is efficient. It is rather a pity that no dimensions of the cross-head were given, as this would tell a lot one way or other in a decision on the best method of locking. Again, it may be that initial slackness in the gudgeon pin, causing hammering, may be the cause of the nuts slacking back gradually. Of course, as they slack back they would make "bad" "worse," and ultimately the bolts would be no longer able to bear the strain, and would break. The remedy for this lies in "letting-to" the cross-head brasses on to the gudgeon pin.

Are the bolts as "elastic" as they might be for the strain? The most economical bolt for resisting shock would be one in which as much of the shank as possible was turned down to the diameter at the bottom of the screw thread. I should suggest that if the bolts are as at A, Fig. 1, they should be altered as B, Fig. 1. The

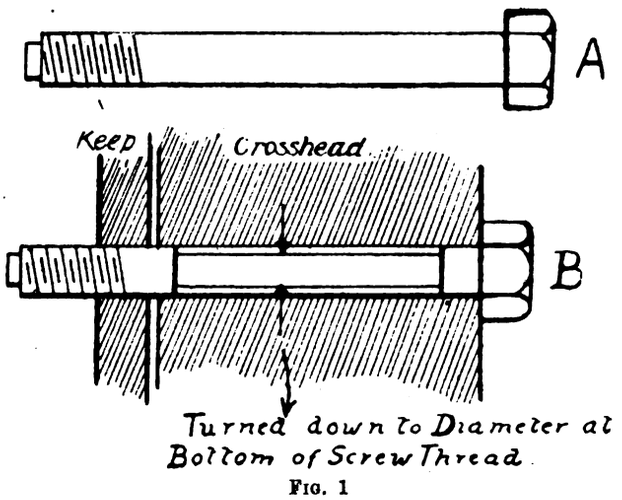


FIG. 1

smallest diameter of the bolt is that at the bottom of the screw thread. Such a bolt as B would absorb shock a good deal better than a bolt like A, and yet be as strong for tensile loads.

There is still another cause it would be advisable to mention as being possibly the reason of the continued accidents. I do not say it is likely, but still it is possible. Supposing one bolt to get tightend a little more than the other, so as to throw the keep across the brass, as in Fig. 2. Then bolt *a* is standing nearly the whole of the load, whilst the slightest screwing up of *b* would produce in *a* a great deal of extra stress. It is easily conceivable, then, that the keep having got across, bolt *a* is in a good deal of initial strain to begin with. When the engine has gone for a bit

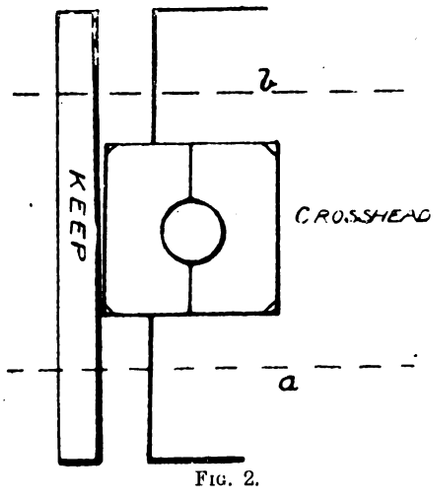

FIG. 2.

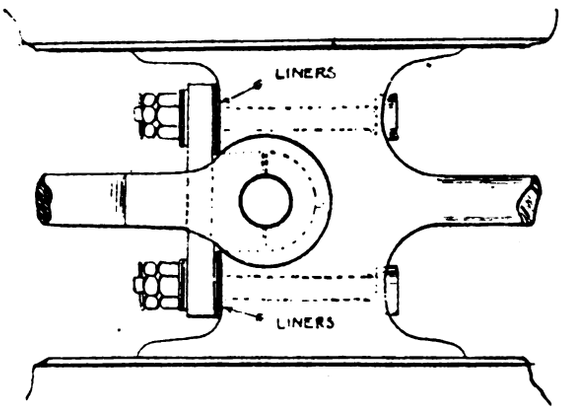
the repetition of stress may very probably be sufficient to fracture it. Most engineers will recollect Wöhler's experiments on repetition of stress. If the bolts *have been screwed up unevenly*, then it is within the limits of common sense to understand that this *may* result in fracture, but I think that in the hands of an engineer such a likelihood would not arise frequently, if at all. Any way, it might be the cause, and it is advisable to mention it. But I should rather prefer myself, if I were "C. B.," to find the cause of the slacking back. Prevent that, and then I think the bolts will remain intact.—T. T.

Answer to No. 608 (*awarded* 7*s.* 6*d.*).—In reply to this question, I had the same experience some few years ago with three different engine sets, but all having the same type of cross-head. At that time the cross-heads were continually giving trouble, and causing the shift engineers great anxiety; in fact, on one occasion both bolts broke on one engine, resulting in the piston going up through the cover, doubling up the connecting rod and smashing the columns, etc. The breaking of the bolts was due to two causes: first, the bolts were not a tapping fit in the holes; and, secondly, the nuts and check nuts were too slack on the bolts. After working a little time the nuts came back, allowing the keep and brasses to jump about, subjecting the bolts to excessive strain, and resulting in a breakdown.

Finally, however, I hit upon a plan which thoroughly overcame the difficulty, and the engines are still in use to-day. The brasses were overhauled, squared up, and adjusted in the cross-head, so that the connecting rod swung easily. The distance between the keep and cross-head, which was about $\frac{5}{16}$in., was then carefully taken, and liners cut to make up the space, each one with a hole through to suit the bolt. The bolts were then withdrawn and the liners inserted on each side of the brasses. When screwed hard up, it made a very solid job of it. Then tin washers, besides the ordinary ones, were also put under the nuts, so that when both the thick and check nuts were tightened up, the split pins through the ends of the bolts had to be driven in, making it impossible for the nuts to move.

Another point worthy of note is that as the brasses were not brass and brass, there being about $\frac{3}{32}$in. between them, the work of taking up the cross-head was a very small matter. The liners mentioned were made up of three $\frac{1}{16}$in.,



the rest being $\frac{1}{64}$in. As the brasses wore, all that was necessary was to take out one or perhaps two each side of the brasses, putting, of course, the same thickness washers under the nuts—in fact, the liners taken out were cut to suit for the washers. Reference to the accompanying sketch will show the whole thing at a glance.—F. B. C.

Answer to No. 608 (*awarded* 5*s.*).—Marine engine cross-heads usually have unequal sized slippers, as they are

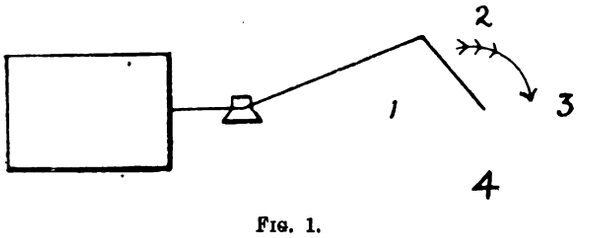


FIG. 1.

really intended to run in one direction only, the greater bearing surface of the cross-head slide taking up the greater thrust. Perhaps the engine described in the query is running in the wrong direction. The arrow in Fig. 1 shows correct direction for running when the larger slipper of cross-head is as in sketch. Another cause of the trouble may be want of alignment of the working parts. The

Digitized by Google

cross-head slides must be parallel with the travel of the piston, and the piston-rod gland should be examined to see that it does not throw a twist on the rod. In setting the slippers on the cross-head, care must be taken that they each bear equally on their slides, and do not force the piston rod out of its proper position. It sometimes happens that when the slippers on cross-head do not travel far enough to overlap the slides, slight shoulders are formed. After any repairs to the engine, such, for instance, as taking up the brasses, the slippers will ride on these shoulders and give trouble. If this is so, the bearing surfaces of the slides should be chipped away, so that at each end of the stroke the slippers just overlap. Similar effects are also caused when the piston does not overlap bearing surface of the cylinder at each end of its stroke. To test for proper alignment of the connecting rod, remove brasses at crank end, and see if the end of the rod is equally distant from the shoulder or collar of the crank-pin in each of the positions 1, 2, 3, and 4. If out of line, and crankshaft is at right angles to the cylinder, adjust by means of its brasses on the cross-head pin or gudgeon. If these points are satisfactory, the fault may be looked for in the bolts themselves. They might perhaps be made a size larger. Lock nuts as a rule hold fairly well, but a split cottar is generally fitted behind them for safety. In quick-running engines it is most essential that all bolts and nuts should be a good fit, or they have a greater tendency to become loosened. To prevent nuts and bolts coming slack, some such means should be taken as sketched in Fig. 2. In one

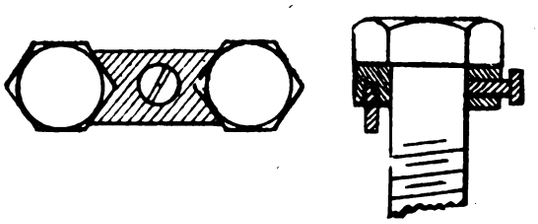

FIG. 2.

case a piece of iron is screwed down which fits the angles of two nuts or bolt heads; this is an old-fashioned but reliable arrangement. The other method, shown here as attached to a set screw but equally well suitable for nuts, is one very much used in marine engineering work. To give a definite answer from the data given in the question is very difficult, although an examination of the engine would probably suggest a remedy at once.—M. M.

GLASGOW TELEPHONE UNDERTAKING.

We have received a copy of the second annual report of the Committee on Telephone Service to the city of Glasgow for the year from June 1, 1902, to May 31, 1903, together with the capital account and balance-sheet. The following abstract will show the position of the undertaking as at the latter date:

Revenue and Expenditure.

Proportion of rentals brought from last year	£12,417	1	5
Gross revenue from rentals for this year, £42,176. 5s. 7d.; less proportion of rentals applicable to year 1903-4 carried to suspense account, £20,714. 15s. 9d.	21,461	9	10
Sundry receipts (including terminal fees, £366. 7s. 5d.)	1,135	11	7
Total revenue	35,014	2	10
Working expenditure (including Post Office royalty, £3,405. 9s. 8d., and terminal fees, £1,497. 15s.)	20,871	2	2
Net revenue	14,143	0	8
out of which the following requirements had to be met:			
1. Interest on loans	£6,642 5 7		
2. Sinking fund	5,806 13 4		
	12,448	18	11
leaving a surplus on the year's operations of	1,694	1	9
Surplus brought from last year	398	7	10
Total surplus	£2,092	9	7

From the above synopsis it will be seen that the surplus for the year just closed amounts to £1,694. 1s. 9d., which, together with the surplus £398. 7s. 10d. brought forward from last year, makes up the sum of £2,092. 9s. 7d., and it is now proposed that the whole amount be carried into a general reserve fund. The capital expenditure for the year just ended has amounted to £78,244. 16s. 2d.; adding the capital expenditure of £192,693. 14s. 3d. previously incurred, there is a total capital expenditure of £270,938. 10s. 5d. The following statement gives the work completed and the remarkable progress the undertaking has made in the last two years:

	Original scheme.	Actually completed. 1901-02.	1902-03.
Completed instruments to be provided	5,250	5,479	9,122
Partially completed lines	1,200	8,787	7,387
Switchboard accommodation (lines)	6,050	7,060	10,826
Number of pairs of cable wires	6,450	14,572	18,171
Mileage of pairs of wires in cables	4,938	11,061	14,029¼
Length of trenching (miles)	22	94	127¾
Number of pipes going out of exchanges	32	126	135
Capacity of pipes going out of exchanges (pairs of wires)	6,900	27,000	31,000
Length of pipes (miles)	32	104¼	127¼
Length of underground cable (miles)	31	113¾	162
Number of ground poles	2,326	691	1,799
Number of roof standards	456	228	243

The service generally continues to be acceptable to subscribers, as may be shown by the fact that during the year now ended the number of orders received was considerably in excess of the preceding year, and the traffic during the year has steadily increased, and now reached the rate of 31½ million messages per annum. The messages per subscriber per day vary in the different exchanges from six to twenty-one, the average throughout the system being 13 per subscriber per day. The traffic in trunk messages, particularly in incoming calls, also shows a considerable increase on the previous year. Considerable attention has been devoted to opening public telephone offices for the use of the public throughout the city, there being now 115 in operation. At May 31 there were 9,112 instruments connected, these being subscribed for by 8,145 persons and firms, of which about 4,600 have never been telephone subscribers before. About 800 orders remained to be executed. Below we give abstracts of the revenue and capital accounts:

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Inspection and repairs—wages, materials, etc.	4,371	14	9

TRADE NOTICES AND NOVELTIES.

Rectifiers.

In our last issue we described the principle of a new type of rectifier (Koch's system) supplied by Messrs. Siemens Bros. and Co., Limited, 12, Queen Anne's-gate, Westminster, S.W. By the courtesy of this firm we are now able to illustrate several classes of the apparatus constructed for specific purposes. The rectifier (Fig. 1) is used exclusively for charging small accumulator batteries from an alternating-current circuit of any ordinary potential or frequency, and is designed for a maximum charging current of eight amperes. In our next illustration (Fig. 2) the parts of the rectifier are shown arranged in switchboard form, the interrupter, three-pole switch, adjustable resistance (for varying the direct current used for excitation), the phase regulator, and the terminals being fixed to a white marble slab 350mm. (13¾in.) by 450mm. (17¾in.). The condenser is fixed in a polished case behind the marble slab and the choking coil in a separate perforated iron case. It can be employed with any ordinary voltage, and gives a maximum charging current of 15 amperes. The rectifiers (Figs. 3 and 4) are designed exclusively to work induction coils from alternating-current circuits. If the primary is suitably wound, the coils may be worked up to their maximum sparking distance, and by the insertion of a resistance in the secondary, the softest of Röntgen tubes will give clearly defined images. This apparatus renders it possible for alternating currents to be employed for X-ray work in a manner hitherto unattainable. The armature of the polarised interrupter operates the contact in such a manner that only currents in one direction pass through the primary coil, the "makes" and "breaks" occurring exactly at the zero periods of the potential of the main current. In consequence, however, of the inductance of the circuit, the direct rectified current flowing through the primary coil lags behind the potential of the main current and is interrupted shortly after its maximum value has been reached, but, as the interruption occurs in the falling part of the curve, sparking at the contact is minimised and a relatively long life for the contact secured. While, however, the apparatus Fig. 3 utilises only one of the alternations of the current, that shown in Fig. 4 utilises both alternations, and so doubles the frequency of the sparks given by the coil. In photography, the times of exposure are greatly reduced by the use of this apparatus with Röntgen tubes constructed for very rapid interruptions. The armature of the interrupter operates the contact in such a manner that the positive portions of the rectified current flow through one division of the primary in one direction, and the negative portions through the other division of the primary in the other direction, the sparks in the secondary circuit being thus always in the same direction. The number of sparks is double that of the periods of the alternating current, but it may be halved by switching off one of the primary circuits. The introduction of the above type of rectifier into this country is extremely welcome.

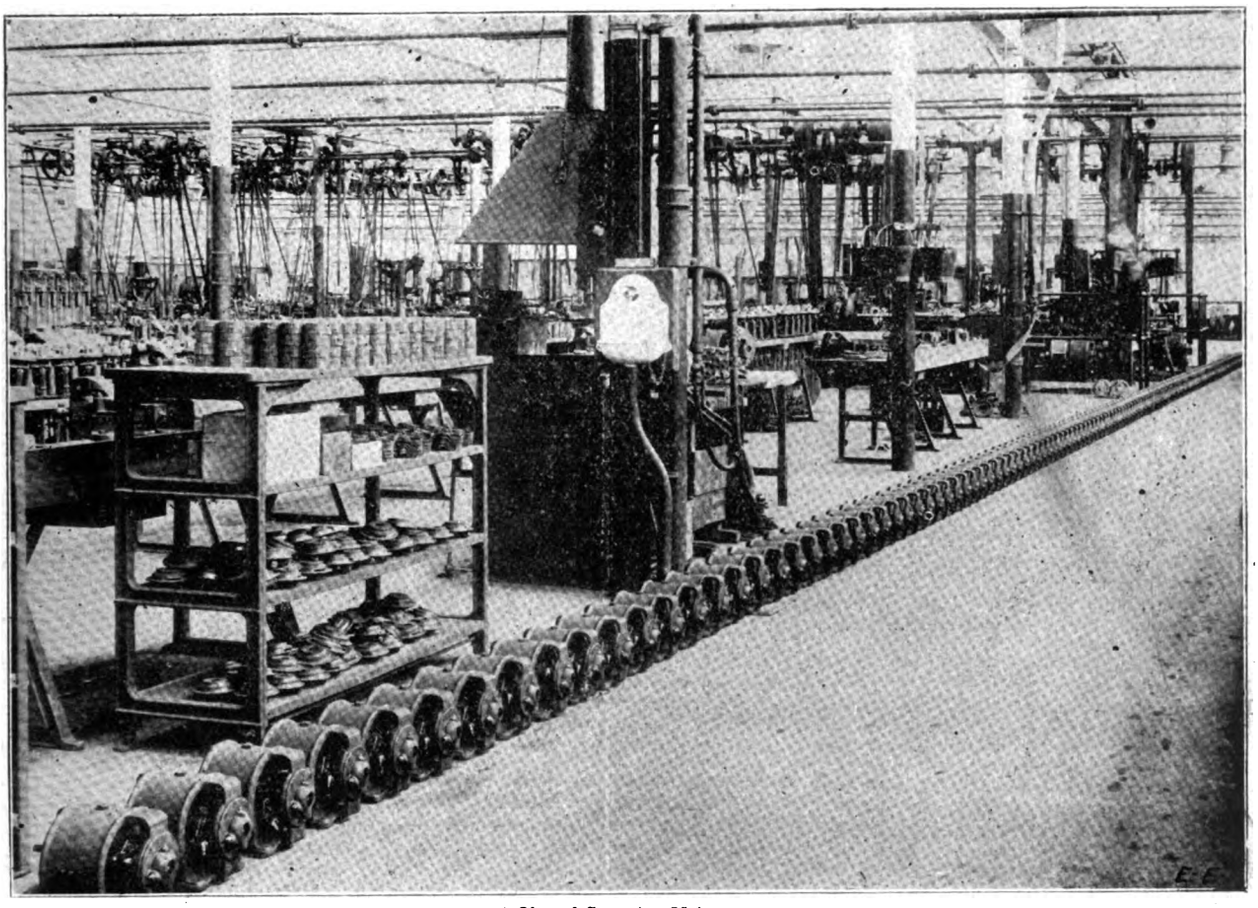
Small Motor Manufacturing.

Our English firms are now well to the fore in the manufacture of small motors, and have recognised the vast scope there is for electric motors now that electric supply systems are so common throughout the country. Amongst the firms in question, Messrs. Crompton and Co. may be specially mentioned. The illustration we give herewith is intended to convey the fact that it is only by manufacturing in quantity that the present

Digitized by Google

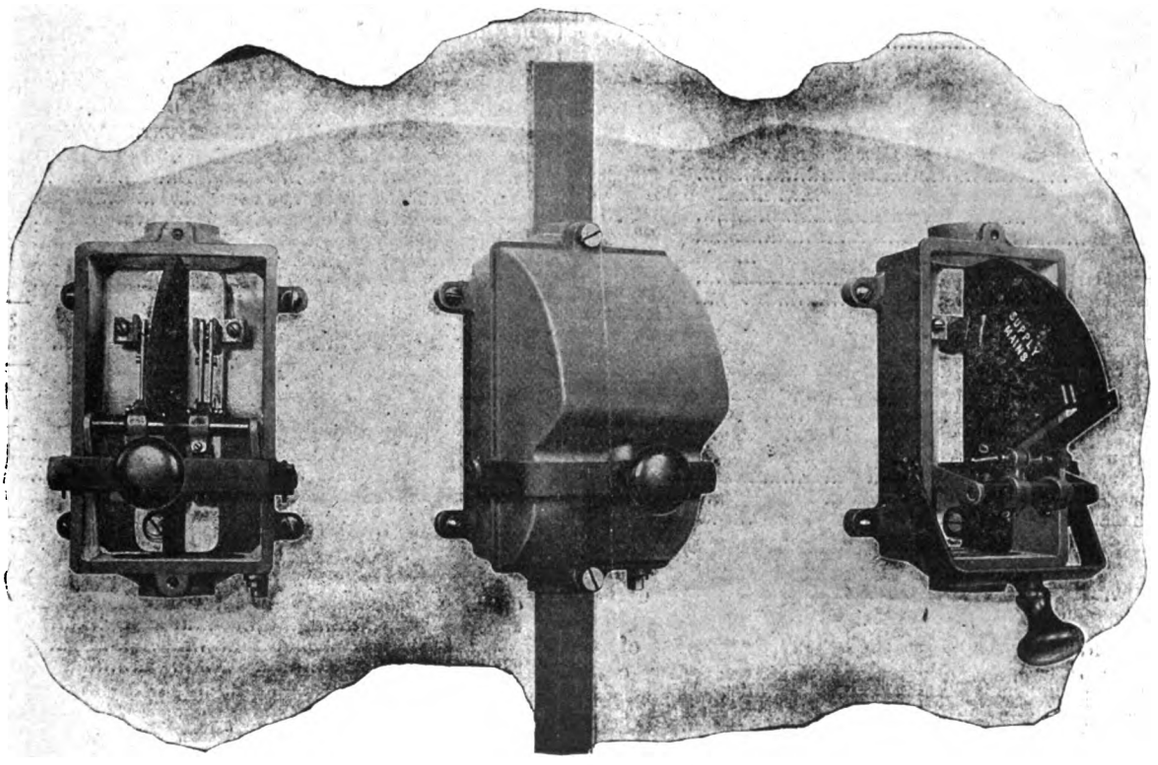
demand can be met for small motors at low prices. The semi-automatic tools with which Messrs. Crompton and Co.'s new works are so completely furnished enables them to carry through the vast amount of repetition work most economically. We need only add that the care bestowed on the manufacture of these motors is no less than that which is given to the larger Crompton machines. These motors are standardised for three different voltages—*i.e.*, 110, 220, and 440. With small alterations of speed these standards are suitable for working on 100, 200, and 400 volt circuits.



A Line of Crompton Motors.

The Holmes-Page Switch.

Through the kindness of Messrs. J. H. Holmes and Co. we are able to give the following illustration of the Holmes-Page patent switch as enclosed in cast-iron boxes. The combination of the box and switch makes it suitable for connection to electric supply companies' mains, and they are also in accordance with the various fire insurance companies' regulations for controlling 460-volt motors. The switch is arranged so as to embody all the features of the Holmes-Page chopper switches. The box is of cast iron and is made practically watertight, and screwed holes are provided at the ends to receive insulated bushes or iron pipes carrying cables. The switch is operated by means of a stirrup handle, which fits outside the box when the cover is on, and it is so arranged that the box cover cannot



The Holmes-Page Patent Switch.

Digitized by Google

be removed without first opening the circuit. The entire switch parts, excepting the two top contact jaws, are dead when the switch is open. The inside surface of the box is thoroughly coated over with a specially-prepared insulated japan, which will not crack or blister when subjected to severe heat or rough usage. The box is provided with suitable means for earthing. The special points worthy of mention are: neatness in appearance; switches are carried on porcelain bases, and are separated by substantial partition, thereby securing a very high insulation resistance. The switch has self-adjusting contacts, and is easy to wire. Another important feature is that the supply main may be brought in at either end, and still be connected to the top contact jaws. The sample switch will comfortably carry 12 amperes at 500 volts, and considerably more at lower voltages. It has been tested to earth and between poles with 2,000 volts alternating current.

GLOUCESTER ELECTRICITY ACCOUNTS.

The accounts of the Gloucester electricity undertaking for the year ended March 31, 1903, show a total expenditure on capital account of £59,332. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are appended.

REVENUE ACCOUNT.

Dr. Expenditure.	£	s.	d.
Coal and other fuel	589	17	6

LEIGH ELECTRICITY UNDERTAKING.

Mr. D. M. Kinghorn, the borough electrical engineer of Leigh, has presented his report to his committee on the working of the Electricity Committee for the year ended March 31 last. It shows that the capital expenditure on that date amounted to £22,271. 6s The total length of mains was 7 miles 1,606 yards, and the number of services laid during the year, 26. A comparative statement of annual progress shows that the number of consumers last year increased to 154; number of 8-c.p. lamps, 11,875; number of motors, 75; number of units sold, 344,880 (plus 453 public clock); maximum load in kilowatts, 264, the load factor being 14·9 per cent. The progress made during the year has been very satisfactory, the increase in the number of units sold being 129 per cent. greater than in the preceding year. The load factor also shows a better demand. A table showing the number of units sold at the various prices indicates a slight falling off in the number of units sold at 7d. and 2½d., but this is more than counterbalanced by the increase of 93·5 per cent. in the units sold at 5d. The increase in the demand for power is exceptional and very gratifying, being nearly four times greater than last year, with a corresponding increase in revenue, which shows that, though the rates are very favourable, the price per unit sold is well maintained. Following we give an analysis of accounts for year ending March 31, the figures in brackets being for 1902: capital expenditure to March 31, £22,271 (£17,373); revenue from electricity supply, £3,466 (£1,989); revenue from meter and motor rents and other sources, £150 (£70); total revenue, £3,617 (£2,060); total costs, £2,184 (£1,150); gross profit before providing for interest charges and sinking fund, £1,433 (£910); percentage of gross profit to capital (outlay during year being averaged), 7·22 (6·43); interest on loans, £635 (£419); sinking fund, £534 (£410); percentage of sinking fund to capital (outlay during the year being averaged), 2·69 (2·89); financial result after payment of all charges, £263 profit (£80 profit); capacity of dynamos, etc., March 31, 450 kw. (200 kw.); maximum load reached, 264 kw. (140 kw.); load factor, 14·9 per cent. (12·31 per cent.); number of 8-c.p. lamps connected March 31 (arcs, incandescents, and motors, equivalent in 8 c.p.), 18,166 (15,853); number of units sold and public clock, 344,880 (151,048); units sold per 8-c.p. lamp (connections during year being averaged), 22·9 (13·8); price charged—private lighting, 7d. and 2½d., or 5d. less 10 per cent. and 3d., power, 3d. and ¾d. and 1½d.; average price obtained—private supply, 4·56d. (4·13d.), power, 1·4d. (1·45d.). From an analysis of costs we find that the generation and distribution costs in 1902 amounted to £635 (1·01d. per unit sold), and last year to £1,526 (1·061d. per unit sold). The general costs in 1902 were £985 (1·56d.); in 1903, £1,896 (1·318d.). The total costs in 1902 amounted to £1,815 (2·88d.); in 1903, £3,066 (2·131d.). Special charges brought the total up to £1,979 in 1902 and £3,260 last year. A summary of financial results shows that for 1903 the principal figures were: capital expended, £22,271; average charge per unit, 2·51d.; gross profit, £1,433; percentage to average capital outlay, 7·22 per cent.; interest and sinking fund, £1,169; surplus, £263.

LEGAL INTELLIGENCE.

METROPOLITAN ELECTRIC SUPPLY.

Compensation for Displacement.

The dispute which had been going on between the London County Council and the Metropolitan Electric Supply Company for considerably over two years with regard to the acquisition by the former of the company's property in Sardinia-street in connection with the Holborn-to-Strand improvement has at length been finally settled by arbitration. Sir John Wolfe Barry was the umpire, and he has just issued his award, which, it may be said at once, is a complete victory for the London County Council, the amount of the award being considerably less than half what the company claimed. The history of the arbitration is very generally known. In pursuance of the powers conferred upon them by Parliament, the London County Council proceeded to compulsorily acquire the generating station and other premises of the Metropolitan Electric Supply Company in Sardinia-street, Lincoln's-inn-fields, for the purposes of the new thoroughfare from Holborn to the Strand. Then arose the question of the amount of compensation the company were to receive for being displaced and having to seek other and suitable premises to carry on their business. The difficulty in the way of an early settlement of the matter was the clause in the County Council's Act of Parliament, which provided that they should reinstate the company elsewhere and pay compensation which was to be assessed on this basis: "A sum equal to the costs and expenses of erecting and fitting a new generating station upon the new site, with new plant of a capacity to generate and supply electrical energy to an output of not less than 4,000 kw., and all expenses." Each party, not unnaturally perhaps, placed its own construction on this clause, the one holding that it was only compelled to pay the cost and erection of four new engines graded up to a capacity of 4,000 kw., the other contending that it was entitled to be compensated for all expenses "contingent" to the displacement of their machinery in Sardinia-street, and the erection of the new plant on the other site. Being unable to agree between themselves the parties had recourse to the law, and in the first place Mr. Justice Farwell, in the Chancery Division, was invited to place his construction upon the clause in question. He held that the arbitrator was debarred from allowing anything more than would cover the cost of four engines graded up to a capacity of 4,000 kw. This decision was appealed against by the company, and the Court of Appeal decided the other way. Then the County Council took the matter up to the House of Lords, and the final decision was given on March 10 last year. It was in favour of the company, the Lord Chancellor explaining that the question was not whether it was reasonable and proper to make provision for contingencies, but whether it had been agreed to between the parties. He held that it had, and the matter thus went to Sir John Wolfe Barry to say how much the company were entitled to receive on this basis. The arbitration proceedings commenced on Jan. 7 this year at the Surveyors' Institute, Westminster, and the hearing lasted several days. The claim of the company amounted approximately to £400,000. Their

Digitized by Google

legal representatives were Mr. Balfour Browne, K.C., Mr. Cripps, K.C., Mr. Ernest Moon, K.C., Mr. C. H. Sargant, and Mr. A. T. Lawrance. For the London County Council, Mr. Fletcher Moulton, K.C., Mr. Boyle, K.C., and Mr. Edward Morton appeared. Mr. C. H. Gadsby, of Victoria-street, London, acted as consulting engineer to the London County Council in the arbitration. Sir John Wolfe Barry, the umpire, had the assistance, as arbitrators, of Sir Frederick Bramwell, Bart., F.R.S., and Mr. Andrew Young. Among those who were called as witnesses during the hearing were Sir William H. Preece, Mr. S. Z. de Ferranti, and Mr. Robert Hammond. As above stated, Sir J. Wolfe Barry's award amounts to £183,150, which averages out at just over £45 per kilowatt, while the sum claimed by the company amounted to £100 per kilowatt. Although no definite offer was made by the County Council, they were advised by their experts that a sum of, say, £150,000 would fully meet the case. The result, notwithstanding the adverse legal proceedings, is, therefore, an all-round victory for the London County Council.

ELECTRIC TRAMWAYS TRUST.

In the Vacation Court on Wednesday Mr. Justice Walton had before him the petition of W. Bratby for winding up the Electric Tramways Trust, Limited.

Mr. Hodge, for the petitioner, asked for an opportunity to answer the evidence of the respondent, which was only filed the previous morning. He was entitled to three days for reply.

Mr. Bramwell Davis, K.C., for the respondent, the liquidator, said he could not resist the application, and the petition stood over accordingly.

NEW COMPANIES REGISTERED.

Wave Power Company, Limited.—Capital, £12,000. Objects: to adopt an agreement with the Morley-Fletcher Wave Power System, Limited, and to carry on the business of an electric light and power and hydraulic power company in all its branches. Registered office: 33, St. Swithin's-lane, E.C.

Whithorn Lighting Company, Limited.—Registered in Edinburgh. Capital, £400. Objects: to acquire the business and assets of the Whithorn Gas Company, and to supply and light with gas, electricity, or otherwise the burgh and vicinity of Whithorn. Registered office: 23, George-street, Whithorn.

Tokio Construction Company, Limited.—Capital, £150,000, in £10 shares. Object: to enter into contracts for the construction, etc., of tramways, light railways, electric lighting works, etc. Amongst the signatories are Mr. A. McIlwraith, 3-4, Lime-street-square, E.C.

Electrical Indicator Syndicate, Limited.—Capital, £5,000. Object: to adopt an agreement with C. Baxter and W. H. Callow to acquire and turn to account patents, etc. Registered office: Dock House, Billiter-avenue, Billiter-street, E.C.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Macao.—The Colonial Office at Lisbon invite tenders for the electric lighting of Macao. Tenders by Oct. 21.

Lisbon.—The Public Works Department require tenders for the public electric lighting of Macao. Tenders by Oct. 21.

Bucharest.—The Government Railways require tenders for the installation of electric lighting and plant for their workshops. Tenders by Oct. 10.

Queensland.—The Deputy Postmaster-General at Brisbane invites tenders for the supply of material for the postal and telegraph service by Sept. 30.

Paris.—The Post and Telegraph Department, Rue de Grenelles 103, invite tenders for (1) 190,000 ko. bronze or copper wire and 94,000 joints, and (2) 12 kilometre submarine telegraph cable.

Kirkcaldy.—The Corporation invite tenders for supply of all fittings for installing the electric light into the memorial halls in Bennochy-road. Tenders by Sept. 12. See advertisement.

Croydon.—The Council invite tenders (1) for the building works and (2) for the smith and ironfounders' work in connection with the extension of the electricity works, Factory-lane, Croydon. Tenders by Sept. 14. See advertisement.

Dublin.—The Port and Docks Board invite tenders for the supply of a 100-ton electric crane. Specification can be obtained at the office of the engineer to the Board, Mr. John P. Griffith, M.I.C.E., Eastwall, Dublin. Tenders by Oct. 5.

London, E.—The Whitechapel Guardians invite tenders for electric lighting of a portion of the infirmary. Specifications, etc., from Mr. F. J. Tootell, clerk, Union Offices, 74, Vallance-road, N.E. Tenders must be sent in by Sept. 12.

Huddersfield.—The Corporation invite tenders for the supply and delivery of about 30 tons of steel tramway rails (girder section), with fishplates, tierods, bolts, trolley poles, bracket arms, overhead-line material, &c. Tenders by Sept. 16. See advertisement.

Worthing.—The Corporation invite tenders for the reconstruction of their storage battery at the electricity works. Specification of the work can be obtained from Messrs. Burstall and Monkhouse, 14, Old Queen-street, Westminster. Tenders by Sept. 7. See advertisement.

Shanghai.—The French Colony propose to instal motor-propelled tramways. Tenders may be sent by Oct. 31, 1903, to Secrétariat de la Municipalité Française de Shanghai. Particulars may be obtained from l'Office National du Commerce Extérieur, Rue Feydeau, 3, Paris.

Brussels.—The Post and Telegraph Department require tenders for 111,500 ko. galvanised iron wire, 5,100 ko. wire cable, 1,875 ko. copper wire, 532,900m. copper wire, 153,650 insulators, etc. Specification No. 200 at above. Tenders by 11 a.m. on Sept. 16 at the Bourse.

Russia.—The Russian Minister of the Interior has sanctioned a plan for the reconstruction of three lines of municipal tramways—namely, those in Newsky, Sadovaïa, and Wassiliostrow districts. Each car is to provide for two classes of travellers, and will accommodate 52 persons.

Utrecht.—The Town Council will receive tenders for supply and erection of a central electric establishment for lighting, power supply, and working tramways. Contract, conditions, etc., to be obtained at the "Gemeente Secretaire" of Utrecht, on payment of 5fl. (8s. 4d.). Tenders by Oct. 1.

Southend-on-Sea.—The Corporation invite tenders for steam dynamo, boiler, and condenser. Specification, etc., may be obtained from Mr. W. E. J. Heenan, M.I.E.E., borough electrical engineer and general manager, Southend-on-Sea. Tenders by noon on Sept. 14. See advertisement.

Bermondsey.—The Borough Council invite tenders for the erection of buildings in connection with extensions to the dust destructor house, electric light station, boiler-house, etc., at the Council's works rear of town hall. Specifications, etc., can be obtained at the Town Hall, Spa-road, S.E. Tenders by Sept. 8.

West Ham.—The Guardians invite tenders for the supply of various articles to the workhouse infirmary and schools for 12 months from Sept. 29, including asbestos goods, electrical fittings, engineers' sundries, etc. Tenders to the Clerk's Office, Union Workhouse, Leytonstone, N.E., by 10 a.m. on Sept. 16.

Johannesburg.—The Municipality require tenders for gas generating plant or for steam generating plant and for gas motors or steam motors, with electric generators and accessories. Particulars may be obtained from the Town Clerk, Johannesburg, or from Messrs. Mordey and Dawbarn, 82, Victoria-street. Tenders by Oct. 19.

Launceston (Tasmania).—The Mayor and Aldermen invite tenders for the supply of 500 or more electric meters. Particulars may be obtained on application to Mr. William Corin, city electrical engineer, Launceston, Tasmania, or to Messrs. John Terry and Co., 7, Great Winchester-street, London, E.C. Tenders by Sept. 28.

Cienfuegos (Cuba).—The Municipal Authorities require tenders for the installation and working of electric lighting. They will pay an annual subsidy of 24,000 piastres for 150 arc lamps of 1,500 c.p. each and 350 incandescent lamps of 50 to 100 c.p. each for street lighting, and 16 to 25 lamps in public buildings. Tenders by 1 p.m. on Sept. 28.

London, E.C.—The East Indian Railway Company invite tenders for the supply and delivery of (1) engine turntables; (2) electric overhead travelling crane, etc.; (3) electric pumping installation; (4) steel material; and (5) feeder panel, insulated cables, etc. Tenders to Mr. C. W. Young, secretary, Nicholas-lane, London, E.C., by 1 p.m. on Sept. 9.

Madrid.—Tenders are invited for a concession for a telephone system with a central station at Palamós and subsidiary stations at San Feliú de Guixols and Palafrugell. A deposit of 2,000 pesetas is required, and tenders must be presented within 30 days from Aug. 14 to the Registry of the Directorate of Posts and Telegraphs, 10, Calle de Carretas, Madrid.

Pietermaritzburg.—The Corporation invite tenders for the supply, delivery, and erection of the necessary poles and overhead equipment for about 5¼ miles of tramway route. Specifications may be seen at Messrs. Mordey and Dawbarn, 82, Victoria-street, S.W. Tenders to Messrs. Ford Bros., 12, Southampton-street, Fitzroy-square, W., by Sept. 7 (noon).

Edinburgh.—The Council invite tenders for the following works in connection with the proposed extension of Macdonald-road electric power station: (1) building works, including excavator, mason, brick, joiner, slater, plasterer, plumber, and glazier's work; and (2) smith and ironfounder's work. Tenders must be sent to Mr. R. Morham, city architect, by 10 a.m. on Sept. 14.

London, S.E.—The London County Council invite tenders for the supply, delivery, and erection in the electricity generating station to be established by the Council at Greenwich of four 5,000-h.p. vertical-horizontal steam-engines, each suitable for driving a three-phase generator. Particulars, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 6.

Bradford.—The Corporation invite tenders for the construction of about 13 miles of light railways and tramways in connection with the Angram storage reservoir works. Plans may be seen and specifications, etc., obtained at the office of Mr. James Watson, M.I.C.E., waterworks engineer, Town Hall, Bradford. Tenders to Mr. Frederick Stevens, town clerk, Town Hall, Bradford, by 10 a.m. on Oct. 1.

Birmingham.—The Tramways Committee require the names of contractors who are desirous of tendering for the supply and delivery of materials and fittings as follows: (Section A) manganese steel points and crossings; (B) tapered steel side poles and bracket arms; (C) suspension ears, pull-offs, section insulators, and other overhead materials; (D) hard-drawn copper trolley wire and stranded steel span wire. Mr. John Price, city engineer, Council House, Birmingham.

Stoke-upon-Trent.—The Corporation invite tenders for the supply and erection of the following plant in connection with the proposed electricity and destructor works: (Contract 10, Section A) pipework; (B) non-conducting covering; (C) water-softening plant. Persons are at liberty to tender for any single section. Specifications, etc., can be obtained from Mr. P. J. S. Tiddeman, Field-place, Stoke-upon-

Digitized by Google

Trent. Tenders to Mr. Jno. B. Ashwell, town clerk, Town Hall, Stoke-upon-Trent, by 5 p.m. on Sept. 11.

Bermondsey.—The Borough Council invite tenders for (Contract No. 12) the construction, supply, and erection of two dust-destructor cells, with furnaces, flues, etc., and storage bins, one water-tube boiler and brickwork settings, one water storage tank, with supports for same, and extensions to the steam, feed, and exhaust piping system; (13) the construction, supply, and erection of two 300-kw. steam generators, two 20-kw. feeder boosters, one 15-kw. motor-balancer, and sundry switchgear and connecting cables. Specifications can be obtained from Mr. Fredk. Ryall, town clerk, and may also be inspected (but not obtained) at the offices of the engineers, Messrs. Kincaid, Waller, Manville, and Dawson, 29, Great George-street, Westminster. Tenders by Sept. 21. See advertisement.

London, E.C.—Tenders will be received until noon on Sept. 28 (a) for the supply of Swedish, Norwegian, or Finland red fir telegraph poles, to be delivered in London, at Northumberland Dock (River Tyne), West Hartlepool, Hull, or Grimsby, at Leven, Fifeshire, and at Swansea, Cardiff, or Newport; and (b) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot, as may be directed. The poles to be felled during the winter of 1903-4, and to be delivered during the following summer at the port at which the creosoting is to be performed. Butt sections, 2in. thick, stamped with the shipper's mark, from not less than three poles, to show the quality of timber offered, must precede or accompany the tender of any person who has not already supplied the Postmaster-General with poles. Forms of tender may be obtained from Mr. S. C. Hoolley, controller of stores, Stores Department, 17-19, Bedford-street, London, W.C.

RESULTS OF TENDERS.

Barnstaple.—The contract for the electric lighting of the music hall has been obtained by Messrs. Alger and Sons at £202.

Henley.—The tender of the Alliance Electrical Engineering Company for a small dynamo, at £149. 10s., has been accepted.

Cheadle (Cheshire).—The following tenders have been accepted by the Council for tramways works: Steel, Peech, and Toser, The Ickles, Sheffield, (Contract No. 1) rails, fishplates, etc.; Askham Bros. and Wilson, Sheffield, (2) points and crossings.

BUSINESS NOTES.

LIGHTING AND GENERAL.

Westminster.—Large extensions of electric street-lighting have been decided upon.

Hull.—Mechanical stokers are being fitted to the boilers at the electric light station.

Brecon.—The Board of Trade have revoked the Brecon Electric Lighting Order, 1900.

Commercial Cable Co.—The directors have declared a quarterly dividend of 2 per cent., payable on Oct. 1.

Worksop.—The Urban District Council have completed the loan of £2,500 for the extension of the electricity works.

St. Helens.—The Corporation have obtained sanction to the borrowing of £3,440 for electric lighting purposes.

Worthing.—An enquiry has been held into the application of the Town Council to borrow £2,835 for electric lighting.

Dublin.—At a special meeting of the Municipal Council last week the two reports given in our last issue were read a first time.

Burnley.—Ten electric arc lamps are to be erected in Sheffield-road, at an estimated cost of £117, in place of existing gas lamps.

Aberdeen.—The Lord Provost's house in Crown-street has been purchased by the National Telephone Company for a new exchange.

Russia.—According to a recent consular report, electric machinery, both for technical and medical purposes, offers a promising field in Russia.

Porthcawl.—The British and American Electric Lighting Company intend to apply for a provisional order for supplying Porthcawl with electricity.

Ventnor.—The Isle of Wight Electric Lighting and Power Company, Limited, are improving the lighting service at Ventnor. A new main cable has just been laid.

Dartford.—A report by Mr. Tait, C.E., upon the question of the lighting of the proposed extension of the workhouse buildings, lighting, etc., is under consideration.

Newton.—The Rural District Council have consented to the Urban Electric Supply Company laying the mains to Kingsteignton, subject to the approval of the Board of Trade.

Fire.—At a fire on Thursday morning at Wintershill Hall, near Bishop's Waltham, the residence of Mr. J. S. Moss, the engine-room and electric lighting plant were destroyed.

Merrow.—The Guildford Electricity Supply Company's application for permission to supply Merrow by means of overhead wires has been referred to the Surrey County Council.

Mutford and Lothingland.—The question of supplying the isolation hospital with electricity has been deferred for consideration with the report of the architect of the hospital.

Redditch.—The Council are prepared to supply Alvechurch with the current in bulk or in any other way required at a charge of 6d. per unit at night and 3d. per unit in the daytime.

Hove Electric Lighting Co.—The directors have declared an interim dividend at the rate of 7 per cent. per annum, payable on Oct. 15 next, for the half year ended June 30 last.

New Book.—On Sept. 16 Messrs. P. S. King and Son will publish a book on the "Tariff Question," by Prof. W. J. Ashley, Dean of the Faculty of Commerce at the University of Birmingham.

Partnership.—Mr. W. C. C. Hawtayne has admitted into partnership his managing engineer, Mr. G. A. Zeden, and the business will in future be carried on under the style of Hawtayne and Zeden.

Bristol.—The Electrical Committee have sanctioned several short extensions of mains, and favourably considered the question of extending the power and lighting mains to the extreme end of Cumberland Basin.

Sandgate.—The Council have granted the application of the Folkestone Electric Supply Company to proceed with the laying of the electric lighting cable and the erection of posts as soon as possible.

City Temple.—The electric light fittings just being installed include four main chandeliers, three having five and one four 100-c.p. lights. There will also be pendants over and under each of the galleries.

Falkirk.—The Electric Lighting Committee have agreed to recommend that the cable be extended to Learmonth-street at an estimated cost of £150. The price of current is to be reduced to 4½d. per unit for lighting as from the October survey.

Fleetwood.—The Council are urging the electric lighting syndicate to lay down mains and to supply electrical energy for lighting public lamps in the streets named, under the powers contained in the Fleetwood Electric Lighting Order, 1890.

River Wear Commission.—The North-Eastern Marine Engineering Company, Limited, have obtained permission to lead electric cables underneath Murray-road to their works and foundry, subject to the payment by the company of a yearly acknowledgment.

Lanchester.—The Consett Iron Company have undertaken to take the electric lighting mains to the gates of Langley Park Hospital without any charge, and to supply electricity for lighting at 4d. per unit. The Hospital Committee will take about 80 lamps, and will invite tenders for the work of fitting up the wires and lamps.

Newport.—The Newport Ratepayers' and Property Owners' Association threaten to oppose the application of the Corporation for sanction to borrow a further sum of £58,000 for increase of electricity plant. The loan is sought for in order to pay the cost of the additional plant for electric lighting and the supply of power to consumers, and has nothing to do with the tramways.

Newcastle.—The Newcastle Guardians have received a report in favour of the entire relighting and heating of the union workhouse at a cost of £15,000, the scheme to include electric lighting and the heating of the house by hot water instead of steam. The city engineer's estimate of expenditure on the proposed quay improvements includes an item of £44,000 for electrical equipment.

London Gazette.—The partnership heretofore subsisting between Otto Rennert, Paul Hensel, and Francis Joseph Zelzer, carrying on business as electrical specialities manufacturers, at 12, Long-lane, in the city of London, under the style or firm of P. Hensel and Co., is dissolved from Sept. 1, 1903. Otto Rennert and Paul Hensel will continue to carry on the business at the same address.

Belfast.—Mr. M'Cowen has been instructed to find out how many customers there would be in the Old Lodge-road district before a main was laid. There has been an increase in the use of electric current during the past year. On the 28th ult. the number of lamps connected was 135,133, as compared with 104,505 for the corresponding period last year, while 43,010 motors were served, as against 30,014.

Ashington.—The Council have accepted an offer from the Northern Electric Supply Company for the supply of electric light for the district. The lamps are to be of 40 c.p., and will be placed 50 yards apart. The scheme will double the lighting of the district at a cost of 30 per cent. less per lamp than under the old system of gas and oil lighting. The Ashington Coal Company will waive their agreement with the Council to supply gas for another two years.

Electric Cableways.—A contract has been obtained by the Brothers Patent Electric Cableway and Crank Company, 26, Victoria-street, S.W., to supply an electric cableway over the Zambesi River at Victoria Falls, for conveying passengers and railway materials pending the erection of the bridge. The span of the cableway is 850ft., and the load to be carried is 10 tons. The site of the cableway is in full view of the falls, and spans a gorge 360ft. deep.

Stourbridge.—Good progress is being made with the electric lighting scheme. The Board of Trade have consented to extend the term of the provisional order by one year. The electric lighting plant is to be laid down on the land recently purchased adjoining the main drainage pumping station, in combination with the proposed refuse destructor. Plans and estimates for a combined scheme for the electric lighting plant and a refuse destructor are now to be obtained.

Radiators.—We have received a new illustrated price-list from the Dowsing Radiant Heat Company, Limited, 24, Budge-row, Cannon-street, E.C., showing a number of elegant prints of their luminous electric radiators, including improved types, for which it is claimed that they give out about 99 per cent. in heat of the energy consumed. We are informed that the firm have had another order from H.M. the King for the Royal yacht, and their patent radiators are also in use at Buckingham Palace.

Fort William Electric Light Co.—The directors recommend a dividend of 2½ per cent. The report states that in comparison with last year the revenue has increased, while the working expenses have been diminished. To meet the increased demand for current for lighting and power purposes a 40-h.p. oil-engine for driving the auxiliary electric plant at Fort William has just been installed. Arrangements

Digitized by Google

have also been made with the principal hotelkeepers that the charge for lighting should now be based on a minimum sum per annum.

New Company.—The business of Stern Bros. has as from June 17 last been converted into a company, in which Messrs. J. Stern, L. Stern, and J. Sonneborn are directors, and will continue their same active interest in the business. No change has been made in the personnel of the firm or its officers, and Messrs. Wallach Bros. will continue to act as the general managers for Great Britain and Colonies. Messrs. Wallach Bros. will continue to sign per procuration for the new company. The style of the new company will be the Stern-Sonneborn Oil Company.

Rochdale.—Messrs. Shepherd and Watney, electrical engineers, of Leeds, in their report upon the electric lighting installation, state that the three engines and dynamos, the booster, and the commutators are all in very good condition. Certain changes are recommended in the switchboard, so that the dynamos and storage cells might be run in parallel. Most of the mains, they say, are defective. The minimum expenditure is estimated at £157, while there is a possible maximum cost of £550. Messrs Shepherd and Watney have been engaged as consulting engineers, and advertisements will be issued for tenders for cable, etc.

Wrexham.—The borough electrical engineer's last report contains the following figures: units generated July, 1903, 29,143; units generated July, 1902, 6,960; used for tramways, 12,725; used for lighting, etc., 16,418. One consumer had been connected during the month—32 lamps of 8 c.p. Total number of consumers connected to date, 131—10,370 lamps of 8 c.p. (exclusive of public lighting). The borough electrical engineer is about to prepare plans and estimates of the cost of a scheme for an extension of the main cables, including suggestions for providing for public lighting, with a view to an application being submitted to the Local Government Board for sanction to a loan for carrying out such extension.

Stock Exchange.—The Stock Exchange Committee have appointed Sept. 10 a special settling day for Marconi's Wireless Telegraph Company's further issue of 39,028 shares of £1 each fully paid, Nos. 157,084 to 196,111; and have ordered the British Electric Traction Company's further issue of 37,500 6 per cent. cumulative preference shares of £10 each fully paid, Nos. 318,938 to 356,437, to be quoted in the official list. Applications have been made to the Exchange Committee to appoint a special settling day in and to grant a quotation to Bruce Peebles and Co.'s 20,000 6 per cent. cumulative preference shares of £5 each fully paid, Nos. 20,001 to 40,000; and the Metropolitan Electric Tramways, Limited, further issue of 185,984 5 per cent. cumulative preference shares of £1 each fully paid.

Blackpool.—Mr. C. Furness, the electrical engineer, in his monthly report for July says: "The output for July was 23,325 units more than for the same month last year—namely, 187,157. We are now able to dispense with the assistance of the Blackpool-Fleetwood Company. The Corporation trams have taken 97,290 units, an increase of 7,686 over last year. Then we have sold to the Blackpool, Lytham, and St. Annes Company 8,770 units. For electric lighting we have produced 81,097 units, an increase of 6,369 units. Yet, in spite of this, wages are down by £75, being £491 against £560 last year. This economy was effected by unloading coal into the bunkers instead of carting it. The coolers or condensers, about which we have heard so much, are expected by some sanguine members of the committee to save £2,000 a year, so that we may yet see the electricity department competing with the gas department as to which can contribute the biggest sum to the relief of the rates."

Hackney.—At last night's meeting the Council received a letter from the London County Council, dated July 21, enclosing the following resolution passed by the County Council: "That, subject to the Borough Council agreeing by resolution to provide out of a sinking fund established for that purpose, or from maintenance account for all renewals and replacements during the currency of the loan, of any of the plant and machinery provided with the proceeds thereof, the borrowing by the Borough Council of the sum of £6,500 to defray further part of the cost of installation of the electric light within the borough, be sanctioned, such sum to be repaid by equal yearly or half-yearly instalments of principal, or of principal and interest combined, within a period of 42 years from the date of the borrowing; and that the seal of the Council be affixed to the formal order in duplicate sanctioning the borrowing, but that such order be not issued until the clerk of the Council shall have received a certified copy of the resolution of the Borough Council agreeing to the condition upon which the sanction is given."

Outing.—On Saturday last, Aug. 29, the first annual outing of the staff of the Stepney Borough Council electricity works took place, the rendezvous being Clacton-on-Sea, on the invitation, we understand, of Mr. Alderman Kearsey (chairman of the Electricity Committee), Mr. Alderman Osman, and Mr. W. C. P. Tapper. The day was gloriously fine, the sun shining brilliantly the whole time. The party travelled from Liverpool-street by special saloon, arriving at Clacton shortly after 10 a.m. A stroll on the fine front of this rapidly rising and attractive seaside resort was followed by an excellent repast at the Osborne Hotel, the chairman for the occasion being Mr. W. Young, with Mr. A. J. Squire in the vice-chair. The toasts of the "King and Queen and Royal Family," "The Electrical Engineers" Mr. Arthur Wright and Mr. W. C. P. Tapper), and "Success to the Undertaking," were proposed and drunk with great gusto, after which the chairman commented on the success which had attended their first outing, and trusted that it was but the forerunner of many such enjoyable meetings. He was sure they all regretted the unavoidable absence of their engineer, Mr. Tapper, who was away on holiday. In the afternoon many of the party enjoyed a pleasant drive round the neighbourhood, visiting Great and Little Clacton, Wherley Woods, and pretty St. Osyth, with its crumbling remains of a seventh-century priory standing amidst beautiful gardens.

TRACTION.

Eccles.—The Monton tramway route will be opened for traffic in the course of a fortnight.

Coatbridge.—Operations have been begun in connection with the laying of rails for the Coatbridge tramways. Messrs. Dick, Kerr, and Co. are the contractors.

Aston.—No time is to be lost in pushing on the work of erecting the new electric tram-sheds in Elkington-street. The whole of the work has to be completed before the end of the year.

Stockton Heath.—A private meeting of the Parish Council has considered plans submitted by the Warrington Tramways Committee respecting the proposed light railway to Victoria-square.

Cheltenham.—Mr. T. A. Nevins has arrived in Cheltenham, and developments in connection with the extension of the Cheltenham and District Light Railway to Leckhampton may be expected.

Tottington.—The Urban District Council has decided to give notice to the Bury, Rochdale, and Oldham Tramway Company requiring them to sell to the Council so much of their undertaking as is within the Tottington district.

Shelf.—There is still no service of cars from Bradford into the district. Last week the public had generally expected the commencement of the service early this week, but the wet weather during the week has again interfered with the little work to complete.

Halifax.—The Town Council have authorised the Tramways and Electricity Committee to purchase and lay a cable in connection with the tramway to Brighouse, at an estimated cost of £4,066. 1s. 6d. It is decided to invite tenders for advertisements on the cars.

Colchester.—The Tramways Committee have appointed Mr. E. A. Jones, of Brussels, rail inspector and tester of rails and fishplates, which are to be supplied by a Belgian firm, the inspector's remuneration to be at the rate of 7d. per ton for rails and 1s. per ton for fishplates.

Overcrowded Tramcars.—At Brentford Police Court a conductor in the employment of the London United Tramways Company has been fined 10s. for allowing overcrowding on his electric tramcar at Twickenham on August Bank Holiday. Nine passengers were fined in connection with the same offence.

Leith.—At the meeting of the Town Council on Tuesday it was finally decided to purchase the undertaking of the Edinburgh Street Tramways Company at Leith, the purchase price being £60,000. The undertaking will in future be worked by the Corporation, and a proposal has been put forward to electrify the system.

Portsmouth.—The Finance Committee, which acts as the Parliamentary Committee of the Town Council, met last Thursday and gave its approval to the draft order for the Hayling Light Railway. The order has already been passed by the Joint Sub-Tramway, Roads and Works, and Finance Committee, which has had the matter in hand.

Paris Metropolitan Railway.—A panic occurred on the Metropolitan Railway at the Hotel de Ville Station on the 27th ult., says a Paris correspondent, owing to a shower of sparks beneath one of the coaches. A number of passengers jumped out of the train, which was just moving off. Many were injured, but none of the cases are serious.

Newcastle.—The members of the Tramways Committee have made a survey of the proposed car route from Scotswood-road to Arthur's-hill, Park-road, Edgeware-road, and Cundercum-road. Afterwards the city engineer was instructed to report as to whether it was possible to alter the level of Edgeware road so as to allow cars to go up to that district.

Eastbourne.—The introduction of motor 'buses by the Corporation has led to a great conflict of opinion in the town, which had its outcome at an "indignation" meeting held on Wednesday, at which there was a crowded attendance. The motor 'bus service was generally condemned, and a resolution was carried, with two dissentients, calling upon the Corporation to provide "a proper system of electric trams."

South Shields.—The Town Council have had submitted to them a new offer from the South Shields Tramway and Carriage Company. They ask for a lease of the tramway lines for 28 years, and offer to relieve the borough of the debt of £9,000 against the tramway account, besides paying interest and sinking fund on the capital cost of electrical equipment by the Corporation. The matter has been deferred to a special meeting on Monday next.

Additional Traffic Returns.—Anglo-Argentine, £1,648 increase; Barcelona Ensanche y Gracia, £200 increase; Barcelona, £13 decrease; Brisbane, £64 decrease (month of July, £10,160, increase £4); British Columbia Electric (month of March), gross earnings £10,352, net income £2,658; Buenos Ayres and Belgrano Electric, £189 increase (month of July, £13,269, increase £1,142); Calcutta, £508 increase; Cape Town (month of April), receipts £16,003, expenditure £8,313; Isle of Thanet Electric, £216 decrease; Mexico Electric (month of June), receipts £46,270; Perth Electric, £161 increase; Port Elizabeth (month of April), receipts £4,292, expenditure £2,281.

Stockport.—The report of the Tramways Committee presented to the Town Council on Wednesday indicated friction with the Manchester tramways authority. The manager of the Manchester tramways had written stating that the Manchester Finance Committee were not prepared to lend money for the construction of new tramways in the district of Stockport, as in the case of reconstructed lines leased to them, and asking for a cheque for £6,892 in respect of lines in Mersey-square and Daw Bank. In reply, the Stockport Committee had written that before payment of the account was made Manchester would be required to put the line in repair at various points in Wellington-road, South Mersey-square, and also carry out their agreement to convey passengers into St. Peter's-square, Stockport.

Digitized by Google

Snowdon.—The North Wales Power Company has contracted with a Scotch firm for six powerful Pelton wheels to drive generators by water power in connection with 13 miles of tramway to be constructed round Snowdon. The route will be in operation next season, and will be useful for tourists. It extends to Beddgelert and Portmadoc, and is narrow gauge.

Cleckheaton.—The Yorkshire (Woollen District) Tramways Company have introduced the ½d. fare on the section of their line in Cleckheaton between the town hall and Moorend. The fare has hitherto been 1d., as on all the other stages, but the distance is comparatively short, and the cars have travelled for several months for the most part empty.

Bilston.—At the last meeting of the District Council the Council decided to support the memorial of the Wolverhampton District Electric Traction Company, Limited, to the Board of Trade for an extension of time for the construction of the line to Ettingshall, and approved the construction of the proposed line *via* Ward-street instead of Hall Park-road.

Cardiff.—A joint meeting of the Public Works and Tramways Committees of the Corporation was held on Saturday to consider a communication regarding the reconstruction of the Penarth-road tramways. It was decided to proceed with the reconstruction of a single line, and that an arbitrator be appointed with regard to the construction of passing places.

Aberdeen.—At the last meeting of the Tramways Committee the question of providing a suitable top for the cars to be used in rainy weather, in order that the outside seats might be utilised, and so prevent overcrowding inside, was discussed, and it was decided to get information, in the first instance, from those cities where these tops are used at present as to their utility.

London and North-Western Railway.—A correspondent says that the directors of the London and North-Western Railway have decided not to electrify any portion of their main lines between Euston and Scotland or Euston and Holyhead. Such a change would involve an enormous outlay, while steam would still be needed for the heavy mineral trains. It is probable in the near future that several branch lines may be electrified, but steam would still be retained for heavy traffic.

Bolton.—The experiment of the Corporation in establishing a motor omnibus service to Darcy Lever, a little industrial suburb lying about 1½ miles from the centre of the town, is being watched with interest by other corporations in Lancashire. It is understood that the cost of laying electric tramlines to Darcy Lever would prove so costly owing to the difficult nature of the road—the village lies in a hollow—as to preclude the possibility of an electric tramcar service thereto proving remunerative.

New South Wales.—The report of the Railway Commissioners of New South Wales for the quarter ended June 30 last, states that the earnings of the tramways for the quarter were £194,394, an increase of £29,371. The expenditure, however, has increased in a slightly greater ratio, but a number of steam cars had been renewed by electric cars out of working expenses. The tramways during the quarter carried 33¼ millions of passengers. The prospects for the coming year in New South Wales are reported to be very favourable.

Wigan.—A crowded meeting has been held in connection with the National Amalgamated Union of Enginemen to consider the action of the Wigan Tramways Committee in refusing to meet Mr. G. H. Copley, the secretary of the union, in regard to alleged grievances of the Corporation tramway employés. A resolution was passed that in the opinion of the meeting the management of the tramways should furnish reasons why some of the men had been discharged, and that the representatives of the employés should be granted an interview.

Manchester.—The Tramways Committee have undertaken to contribute to the city rate out of their surplus revenue a sum sufficient to meet the annual interest and sinking fund charges upon a loan of £100,000, the first instalment payable by the Corporation to the Royal Infirmary authorities for the infirmary site. The Tramways Committee propose to supersede the "cow-catcher" form of lifeguard on the electric cars for the Hudson-Bowring guard, which is of the "gate and carrier" type. Experiments are at present being made with the new guard.

Scarborough.—The question of the desirability or otherwise of the Corporation acquiring the tramways which are about to be laid at Scarborough is agitating the minds of the ratepayers. On Friday the Streets Sub-Committee recommended to the Streets and Buildings Committee that the tramways company should be approached with a view to ascertaining on what terms the company would sell their rights previous to construction. This recommendation, which the full committee decided to act upon, has reopened the question of municipal ownership.

Soothill Upper.—At the last meeting of the District Council on the subject of the proposed application for a provisional order for electric tramways from Dewsbury to Soothill Upper, a letter was read from the Town Clerk of Dewsbury, stating that he had laid before his Law and Parliamentary Committee the suggestion as to co-operation in a scheme for the construction of tramways from Dewsbury to Leeds-road, Hanging Heaton, and Shaw Cross, but in the present year they could not undertake this work. The scheme will probably be shelved for a time.

Gravesend.—The total number of passengers carried during the first 12 months' operations of the Gravesend and Northfleet electric tramways amounted to 2,479 329, which is equal to about 60 times the population of the whole district. On August Bank Holiday, 1902, Easter Monday, 1903, and the day of the hospital fête, nearly 15,000 persons were carried each day, and as splendid weather was experienced on Whit Monday, 28,000 people patronised the tramways. The second year of electric traction commenced on August Bank Holiday with the issue of over 37,000 tickets.

District Railway.—With reference to the contract which, as announced last week, has been let to the British Thomson-Houston Company for the entire control equipment of the District Railway, we are able to state that the terms of the contract call for the equipment of 40 trains in seven months, so that shortly after that the electric trains will be running on the Inner Circle. The steam trains will be taken out of service as they can be replaced by the electric trains, so that there will be no interference with the regular service. The contract for the motors has not yet been placed.

Motor Regulation.—The Prime Minister has sent a circular letter to the prefects of all the departments, instructing them to exercise supervision over all municipal decrees relating to motor traffic. As a general principle, the issue of local regulations imposing a limit of speed inferior to the average rate of a horse at a trot is not to be sanctioned. It should be explained that, while municipal authorities in France have the right of enacting decrees relating to traffic on public highways, such decrees are by law subject to the veto of the prefect, who is the direct representative in his department of the Home Office.

St. Helens.—At a meeting of the Electric Supply and Tramways Committee the town clerk reported that at an inquest held on the body of a woman killed in Liverpool-road by being knocked down by an electric car, the jury had made a presentment to the effect that the Corporation should take steps to have Arthur-street made into a Board of Trade stopping place owing to the heavy traffic in the neighbourhood. He also reported that the corner of London-road and Peter-street was a Board of Trade stopping place, and the committee gave instructions to the engineer to make observations of the amount of traffic at Arthur-street and Peter-street respectively.

Plymouth.—A report submitted to the Tramways Committee for the five weeks ending Aug. 22 last shows a net increase of receipts over the corresponding period of 1902 of a few pence short of £300. During the five weeks ending Aug. 22 823,997 passengers were carried over the five routes. The total receipts from all systems for the five weeks amounted to £3,409, the total for the year up to Aug. 22 being £12,933. 11s. The expenses, including interest and sinking fund, are given as £10,525. The mileage of the cars for the past five weeks was 68,335 miles, the total receipts per mile being 12·27d., the West Hoe system showing the lowest average per mile (6·88d.).

Barrow.—The ss. "D'Tarmigan" has arrived at Barrow from Ghent with a cargo of 300 tons of steel rails, being the first consignment of rails from the Belgian firm who secured the contract for their manufacture in connection with the electrification of the tramway system. It was expected that the work of reconstruction would be commenced last Monday, but so far nothing has been done in the direction of tearing up the permanent way, and it is not likely these operations will be commenced ere another week is passed. The building operations at the tram depôt are preceding apace, but some time may elapse before they are completed ready for the reception of the cars, which are ready for delivery.

Darlington.—There has been introduced on to the works in connection with the construction of the Darlington tramways a new labour-saving contrivance, which is the invention of Mr. B. J. Pattison. The machine mixes the concrete more satisfactorily, and so facilitates work as to save from 50 to 75 per cent. in labour. The machine is constructed with wheels adapted to run on the rails after they have been fixed to gauge, and the concrete is deposited directly in the trench. In each journey of 40 or 50 yards about two cubic yards of concrete are mixed. During the short test to which it has already been subjected the mixer has proved capable of concreting a pair of rails 45ft. in length within the hour.

An Obstruction Remover.—A patent has been taken out by John Carr, of Hull, for obstruction removers for tramcars. An obstruction remover for tramcars, motorcars, cable-cars, and the like is formed by a tray or shoot supported between brackets by studs on the tray entering slots or grooves in the brackets. Either or both of the slots in each bracket are inclined, so that when an obstruction causes the tray to move backwards the tray dips downwards at the front and lifts the obstruction. The studs may have rollers on them to reduce friction. Guards may be placed at the sides of the tray to prevent the brackets from striking the obstruction. In a modification the tray has only one stud at each end, and is counterweighted to rest normally on a bar.

London United Tramways Co.—On the evening of the 28th ult. 1,500 employés of the London United Tramways Company in the chief depôt, Chiswick High-road, were entertained by the directors on the occasion of the annual meeting of the provident society, which is worked in connection with the Company for their benefit. Dinner was provided, the chair being taken by Mr. J. Clifton Robinson, the managing director of the Company. During the year the subscriptions to the society amounted to £793. The sum of £1,010 had been disbursed in sick pay and funeral allowances. Subscriptions amounting to £390 had been received from the directors. There was a balance of £854. The number of members had increased from 800 to 1,400 during the year.

Manchester Suburban Tramway.—The Manchester suburban tramway scheme, which was so much talked of some months ago, has been definitely dropped. The idea, it may be remembered, was to connect up, by means of a light railway, the suburbs on the south side of the city, the lines running from Stretford through Sale, Northenden, Gatley, and Cheadle to Stockport, and on the other side of Stockport as far as Mottram. It was also proposed to buy up land in the districts thus tapped, so that the syndicate should be able to obtain the benefit of improved values resulting from the tramway conveniences. The Manchester Southern Tramways were

Digitized by Google

first in the field in some of the districts, and in others the opposition to parliamentary powers it was thought would have been too strong.

Dundee.—At a meeting of Dundee and District Committee of the County Council the clerk submitted a letter from Mr. Balfour, the promoter of the proposed electric tramway between Dundee and Broughty Ferry, in which he stated that he had now completed agreements with the various road authorities and landowners in connection with the scheme, and that he would now be pleased if the matter was brought before the District Committee in order that he might secure their consent and co-operation in carrying it out. It was pointed out that the route would be from the existing eastern boundary of Dundee along the Broughty Ferry-road to a point where the road first crossed the Dundee and Arbroath Railway. At that point the proposed line would run along a new road through Mr. Guthrie's estate. Consideration of the subject was delayed.

Leeds.—On Saturday a trial run was made over a new tramway route which will be opened for public traffic this week. It has been decided to adopt the Westinghouse type of slipper brake on the electric cars. The Board of Trade, after inspection, has recently permitted the speed of the cars to be accelerated on nearly all the sections, and it is understood that a further concession of the kind will be made by the central authority, if the brake power is increased to warrant it. The Leeds cars are at present provided with two brakes, the ordinary hand one and an electric appliance. The new one will take the place of the latter; but the change will be made gradually, as the old electric brakes are worn out. The steepest gradients, however, will have the first consideration. The cost of this improvement will be between £8,000 and £9,000.

Railway Motors.—The Glasgow correspondent of the *Financial Times* says the Great North of Scotland Railway is contemplating the inauguration of services of motor carriages to supplement the suburban train services, and also to connect outlying districts with the railway. The idea has, no doubt, been suggested by the fact that the Suburban Tramways Company are shortly to open their lines, and the Great North of Scotland Railway is seeking to improve its suburban service before it is actually compelled to do so by a falling revenue. The motor carriages will carry 50 or 60 passengers each. The North-Eastern Railway has commenced its service of motor 'buses in North Holderness, between Beverley and Belford. The 'buses resemble the ordinary electric tramcar, and provide accommodation for 16 passengers. They are propelled by 24-h.p. four-cylinder Stirling motors, giving an average speed of 12 miles an hour. It is proposed at present to make four journeys daily in each direction.

Visitor from Melbourne.—Mr. W. S. Sprigg, who represents the Melbourne Tramways Company, is now in Cardiff after having visited London, Glasgow, Liverpool, Norwich, and other towns. His object is to ascertain the respective qualities of the cable, trolley, and conduit systems. Seen by a *Western Mail* representative, Mr. Sprigg expressed satisfaction with the way in which the Cardiff streets are laid out. He had not seen anything like it in any of the other towns he had visited. After a visit to the electrical works, Mr. Sprigg was not converted to the trolley system. His words were: "I can make more money out of the cable system than you can do in Cardiff with the trolley system." In a general conversation, Mr. Sprigg said, "You have a good system, and it ought to pay, but it never will unless you let it to a company. We know in Australia what these workmen's combinations mean, and they will ruin your business unless you place the tramways in the hands of a company." "Then," he said, "you will have a big amount towards the reduction of your rates."

West Ham.—The labouring classes in this district are greatly concerned about some new by-laws which the Borough Council, as the tramway authority, propose to put into force. "No person," say the proposed by-laws, "shall eat food or fruit upon any car, or deposit remnants of food or fruit in or upon any car." And again, "Any person whose dress or clothing might, in the opinion of the conductor, soil or injure the linings or cushions of a car or the dress or clothing of any passenger, shall not be entitled to enter or remain in or upon a car." The first by-law, according to an official explanation, is to guard against what are called "fish suppers," which the labouring classes have hitherto been indulging in when travelling by the electric cars. There is really no objection to passengers eating fruit or such like delicacies so long as they refrain from depositing the remnants on the cars. With regard to the second proposed by-law, we predict at once that it will be found to be unworkable. After all, the workingman in such a district as West Ham is the chief customer of the tramways, and to debar him from travelling on the cars in his working clothes—that is what the by-law practically means—would not only result in inconvenience and annoyance to the labourers, but would be suicidal on the part of the Corporation, whose first duty to the ratepayers is to make the undertaking pay at all costs. Then to place the discretion of deciding whether a man's clothes would "soil or injure the linings or cushions" in the hands of the conductor—himself a member of the working classes—is too ridiculous. The matter has been taken up by the National Union of Gas Workers and General Labourers of Great Britain and Ireland, and will not be allowed to rest where it is.

London County Council Trams.—The traffic returns of the London County Council's tramways for the week ending the 22nd ult. show receipts amounting to £10,487, as against £8,057 for the corresponding week last year. For the 144 days, ending at this date, of the present financial year, the total takings amounted to £207,489, as against £177,462 for the corresponding period of last year. Passengers carried for the week numbered 2,634,690. The mileage is now 39⅞, as against 26⅝ for the corresponding period of last year. While the new electric tramways on the Tooting lines are proving a great success, some difficulty is being experienced in connection with the altered arrangements on the Streatham cable route. Pending the electrification of this line, the County Council decided to have certain of the new electric cars fitted with special apparatus, so that they could be run from the termini at the bridges to Kennington by means of electricity and then over the existing route from Kennington to Streatham by cable. Doubts were freely expressed as to whether the cable was sufficiently strong to stand the extra strain of the new cars, which are much larger and heavier than the old ones, and these fears have since been justified. Of the 20 electric cars fitted for working on the combined systems about 10 or 15 have been running daily during the past two or three weeks, and observations go to prove that the added strain of a large number of cars would be too much for the cable. It is understood, therefore, that the original scheme for combining the cable and electrical system is to be abandoned, and it may be confidently expected that the conversion of the cable route to electric traction will be pushed on as soon as possible. The improvement of the facilities in South London has given rise to a movement in Streatham and district to induce the County Council to extend its tramways from Streatham to Norbury, so as to connect with the Croydon system at the county boundary, a mile separating the two points. There is rather a steep hill to be negotiated—Streatham Village Hill—but it is not expected that this will present difficulties that cannot be surmounted by electric traction. A petition setting forth these views is being extensively signed by ratepayers in Streatham and the neighbourhood for presentation to the Wandsworth Borough Council and the London County Council.

PROVISIONAL PATENTS, 1903.

AUG. 24.

18250. Improvements in thermal cut-outs. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18251. Improvements in processes of insulating coils. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18252. Improvements in speed-regulating devices. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18253. Improvements in magnetic controlling devices. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18254. Improvements in a combined socket-shell and shade-holder for incandescent electric lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18255. Improvements in methods of sealing metal into glass or other vitreous material. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18256. Improvements in time-limit controllers for circuit breakers. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18257. Improvements in electric switches. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

AUG. 25.

18304. A water-wheel for the generation of power for electricity or other purposes. Alfred Phillips, 4, Sussex-street, Hartlepool.

18318. An improved electric incandescent lamp. George Wallace, 68, Victoria-street, London.

18319. Improvements in electric battery jars. Arthur Ford Lloyd, 63, Cavendish-street, Brighton.

18323. Improvements in machine for making battery grids. Thomas John Coster and Smith Storage Battery Company, 62, St. Vincent-street, Glasgow. (Complete specification.)

18334. The electrical treatment of milk for the separation of cream. Hutchinson Hunt, Sydney Aston, Mersey Rose, and Joseph George Howard, 23, Southampton-buildings, Chancery-lane, London.

18336. Improvements in electrical interrupting devices for currents, particularly those of high intensity. Thomas Joseph Murphy, 55, Chancery-lane, London. (Complete specification.)

18343. Improvements in electric vapour lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18344. Improvements in electric lamps. Edgar Alfred Carolan, 83, Cannon-street, London. (The General Electric Company, United States.)

18354. Improvements relating to electromagnetic rail brakes. Carl Adolf Wilde, 45, Southampton-buildings, Chancery-lane, London.

18376. An improved connection block for electric conductors applicable also as an insertion contact and ceiling rosette. William Phillips Thompson, 6, Lord-street, Liverpool. (The firm of O. and H. Keller, Germany.) (Complete specification.)

AUG. 26.

18383. Improvements in trolley pulleys for electric tramcars or railways to facilitate the finding of the trolley wire. Walter Rhodes, 22, Bond-street, Leeds.

Digitized by Google

18390. Improvements in the construction of electric insulators. Albert Edward Mitton, Richard Whitehouse, and Edward Blakemore, 2, George-street, Parade, Birmingham.

18393. Improvements in electrical indicating instruments. Thomas Albert Briggs Carver, 8, Windsor-quadrant, Kelvinside, Glasgow.

18398. Improvements in and relating to automatic electric signalling. Harold Hawthorne, 16, Montague-street, Russell-square, London.

18411. Improvements in or relating to the steps of electric tramcars and like vehicles. John Farrer Mason, 8, Quality-court, Chancery-lane, London.

AUG. 27.

18453. Improvements in dynamo-electric machines. Cenek Macku, 6, Bank-street, Manchester. (Complete specification.)

18485. Improvements in secondary or storage batteries. Harold Wade, 111, Hatton-garden, London. (Hugh Rodman, United States.) (Complete specification.)

18513. Improvements in apparatus for determining the magnetic properties of metals. The British Thomson-Houston Company, Limited, and Frank Holden, 83, Cannon-street, London.

18536. Improved means and apparatus for controlling electric motors. Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Bullock Electric Manufacturing Company, United States.)

AUG. 28.

18550. An improved construction of commutator for dynamos and electric motors. John Maclean, 100, Wellington-street, Glasgow.

18551. Improvements in brush-holders for the commutators of dynamos and electric motors. John Maclean, 100, Wellington-street, Glasgow.

18555. Improved section insulator for overhead wire systems of electric traction. John Henry Luby, William Harris, and Joseph John Ballard, Lloyd's Bank-buildings, Bristol.

18556. Improved adjustable crossing for overhead wire systems of electric traction. John Henry Luby, William Harris, and Joseph John Ballard, Lloyd's Bank-buildings, Bristol.

18557. Improvements in and relating to points for overhead wire systems of electric traction. John Henry Luby, William Harris, and Joseph John Ballard, Lloyd's Bank-buildings, Bristol.

18558. Improved clip for clamping or binding the wires to fittings in overhead wire systems of electric traction. John Henry Luby, William Harris, and Joseph John Ballard, Lloyd's Bank-buildings, Bristol.

18581. Improvements in a system for electric lighting of railway trains. Henry Leitner and Richard Norman Lucas, Lynton, Dartnell-park, Byfleet.

18586. Improvements in porcelain and other electric insulators. William Edward Langdon. John Crisp Fuller, and George Fuller, 33, Chancery-lane, London. (Complete specification.)

18598. An improved automatic electro-mechanical cut-out. James Ernest Spagnoletti, 53, Chancery-lane, London.

18602. Improved carrier for an incandescent electric lamp. Ernest Taylor, 22, Southampton-buildings, Chancery-lane, London.

AUG. 29.

18624. Improvements in electric lamps of the character known as vapour lamps or vapour arc lamps. Charles Orme Bastian and Albert Edward Salisbury, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

18625. An improvement to incandescent electric lamps to enable variation of their candle-power. Thomas Woodward Bullock, 13, Cambridge-street, Prescot, Lancs.

18631. Improvements in or relating to trolley heads for electric tramcars. James Eagles and James Eagles, 3, Sagar-street, Hough-lane, Salford.

18653. Improvements in electric switchboards and fuseboards. Herbert James Read, Chalfont, Stanhope-road, St. Albans.

18680. Improvements in means for controlling electrically-operated elevators. Hans Lauritz Eriksen and the Company Koefoed Hauberg, Marstrand, and Helweg, Aktieselskabet Titan, 18, Buckingham-street, Strand, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published September 17, 1903.

1902.

16205. Dynamo-electric machines. Heyland.

18429. Electric heater for liquids. Briggs.

18872. Electrical switches. Cox.

18925. Rheostats for starting electric motors. Lake. (The General Electric Company.)

18958. Apparatus adapted for indicating or for opening or closing a circuit on change of the direction of flow of electrical energy. Andrews.

19283. Electric transmission and controlling gear. Johnston and Dobbs.

19305. Apparatus or device for use in applying bituminous or similar composition to conduits for electric cables, or to drain pipes, or like goods to form jointing rings thereon. Oates.

21734. Telephone apparatus. Houbigant.

22649. Method of and appliances for operating trolley line and other switches. Dawe.

23257. Flexible metallic tubing for armouring insulated electrical conductors. Bowley.

23421. Rontgen-ray and like apparatus. Cox.

1903.

459. Prepayment attachment for electricity meters. Swan.

5240. Conduits or casings for electric conductors. Knight and Nagel.

7561. Electric current controllers. Bradley and Allen.

7789. Telephone systems. Paul and McDougall.

10190. Commutator contact protector for use on commutator of electrically-ignited internal-combustion engines. McClymont.

12194. Apparatus for the production of electrolytic deposits. Müller.

13061. Fuse head for electric blasting. Render.

13282. Coupling device or clutch for electric motors. Wüst-Kunz.

15506. Armatures for electric induction motors. Thompson. (Electricitäts-Gesellschaft Alioth.)

16138. Electrical signalling systems for railways. Mills and Piddington.

SUMMER MEETING OF THE INSTITUTION OF MECHANICAL ENGINEERS.

After an interval of 21 years the summer meeting of the Institution of Mechanical Engineers has once more been held in Leeds. The first paper dealt with was by Mr. H. Ade Clark, of the Yorkshire College, Leeds, on the "Diesel Engine." The following abstract includes recent records obtained by the author.

The Diesel Engine.

For the purposes of this paper the author visited the works of Messrs. Carels Frères, Ghent, Belgium, where he made four trials on the 80-b.h.p. engine at that time on the erecting bed. The data and results of these trials are given in Table I. As no preparations for a trial had been made, these results are not so complete as for the other two engines. The engine was connected by a belt to an overhead shaft, which was belted to a four-pole dynamo and to a motor running light. The output of the dynamo was absorbed by a water resistance. The petroleum tank supplying the engine was weighed immediately before and after each trial. Indicator cards were taken every five minutes, and the revolutions by a counter attached to the air-pump rocking lever. The oil used on this occasion was a Texas crude petroleum, a sample of which has since been tested at the Yorkshire College, with the following results: specific gravity, 0·922; gross calorific value, 19,300 British thermal units per pound.

TABLE I.—80-b.h.p. Diesel Engine: Test of Single-Cylinder Diesel Engine at Ghent on Feb. 7, 1903,—Summary of Results.

Load	0·25	0·5	0 75	Full

Thermal efficiency on the B.H.P. (per cent.)	19·7	27·3	—	31·2

On March 7, 1903, the author made complete trials on a double-cylinder 160-b.h.p. Diesel engine at the works in Ghent. The indicated horse-power was obtained by taking indicator cards from each cylinder every five minutes during one hour, and the load trials were each of one hour's duration and of half an hour when running light. The data and results are given in Table II.

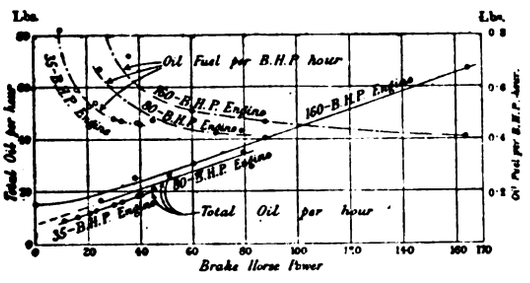

FIG. 1.—Oil Fuel for Diesel Engines.

In Fig. 1 three pairs of curves are shown, one pair for each of the engines tested by the author, the lower curves (straight lines) showing the oil consumption of these engines as the load varied. These curves of total consumption show well the action of the governor in cutting down the oil supply to the requirements of the engine, a result not so nearly approached by other types of oil-engine. They also show that the oil supply is directly proportional to the horse-power, except at very low loads—that is, loads below 25 per cent. of the normal. The upper three curves show the oil consumption per brake-horse-power hour. It will be observed that those curves descend to nearly the same at top loads, and that the rate of increase of consumption is not high, even down to half load, both facts, which point to the economy of this engine when distributed in small units, making it unnecessary to concentrate the power in large units and then use expensive transmission to the points where the power is required.

TABLE II.—160-b.h.p. Diesel Engine: Test of Two-Cylinder Diesel Engine at Ghent on March 7, 1903.—Summary of Results.

The performance of the 160-b.h.p. engine under variation of load was as follows: Load on the dynamo,

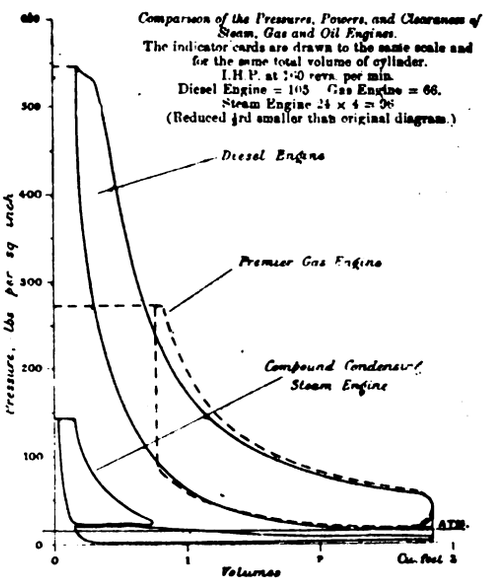

FIG. 2.

700 amperes at 115 volts—that is, 108 h.p.; tachometer reading, 89. The whole load thrown off at once, the tachometer ran up to 96·2, and settled back to 88·7 in about a minute. The engine running light, tachometer 91, a load of 700 amperes at 115 volts was put on at once, when the lowest reading of the tachometer was 87·8, and the engine settled back to 90 in about half a minute. Indicator diagrams were taken during the trial of 160-b.h.p. engine on March 7, 1903. One card shows the starting of the engine under air pressure; then come a series of cards showing the development in the body of the card under various loads, the action of the governor

Digitized by Google

in giving more oil for more work being well shown. The whole of the cards taken in a given run are very regular, any single card being very little different from the mean.

In Fig. 2 is shown a comparison of the pressures, powers, and clearances of three types of engine—namely, the compound condensing engine, using high-pressure steam with jacketed cylinders; the scavenging type of gas-engine, using gas of 600 British thermal units per cubic foot; and the Diesel engine, using crude petroleum. The indicator cards there shown are drawn to the same scales and for the same total volume of cylinder. The clearances are as follows: the steam-engine, 3·5 per cent. of the volume of the horse-power cylinder; the gas-engine, 27 per cent. of whole volume; the Diesel engine, 7 per cent. of the whole volume.

Further trials were made in England to confirm those on the makers' testing beds. Table III. gives the results of a trial made on the 35-b.h.p. Diesel engine at Harrogate on May 8, 1903—that is, about 12 months after the trials made in April, 1902. Taking trials at 33 b.h.p, the results are as follows:

Year.	B.H.P.	I.H.P.	Eff.H.P.	Oil per hour—I.H.P.	Oil per hour—B.H.P.
1902	33·1	46·88	70·7	0·336	0·476
1903	33·2	48·80	68·1	0·344	0·505

* Effective horse-power at full load, 80.

Table IV. gives the results of a trial made in London on May 16, 1903. This engine is of 80 b.h p. at 160 revolutions, and was made by Vereinigte Maschinenfabrik, Augsburg, and there is, therefore, additional interest in comparing it with the trial given in Table I. on the engine of the same size made by Messrs. Carels Frères, Ghent. In the trial at half load the maximum indicated horse-power was 73; the minimum indicated horse-power, 44; the mean being 62 i.h.p., taken from 52 indicator diagrams. In the three-quarter load the highest indicated horse-power was 99, the lowest indicated horse-power being 69·2, and the mean indicated horse-power was 81·5 from 36 diagrams. In the no-load trial the highest indicated horse-power was 31·2, the lowest indicated horse-power 16·35, and the mean from 26 cards, each containing five or six diagrams, was 23·8. The governor "hunted" a little when working without load. This trial was made when the engine was running under load for the first time since its erection at Messrs. Stafford Allen and Sons', and was not then out of the makers' hands; consequently the no-load indicated horse-power is probably a little high, and a month's running of the engine would probably reduce this.

Table V. is condensed from a more detailed statement by the author, and is a comparison of cost for three sizes and types of engine.

TABLE V.—Total Costs in Power Production.

Type of engine.	B.H.P.	Capital cost—Total.	Capital cost—Per B.H.P.	Annual cost—Total.	Annual cost—Per B.H.P.	Cost per B.H.P. hour.
		£	£	£	£	Pence.
Diesel	35	695	19·8	233·05	6·66	0·59
	80	1,075	13·44	348	4·35	0·39
	160	1,916	14·28	582	3·63	0·32
Gas	35	647	18·5	270·5	7·73	0·69
	80	1,142	14·25	466	5 82	0·52
	160	1,836	11·98	726	4·45	0·40
Steam	35	850	24·3	350	10	0 89
	80	1,330	16·7	568·2	7·1	0·63
	160	1,976	12·4	887	5·5	0·49

Initial capital cost includes land, buildings, and plant. Annual charges includes interest on capital, maintenance, and depreciation for buildings, and also for plant, fuel, oil and water, and wages. The gas-engine taken for comparison is the Crossley using a Dowson gas producer. The steam engine compared with is the high-speed compound-condensing engine. The fuels are: for the Diesel, crude petroleum at 45s. per ton; for the gas-producer, anthracite coal at 24s per ton; for the steam-engine, coal at 12s. 6d. per ton. The oil consumption for the Diesel has been taken in each case as the mean between the full and half power rates of consumption. The fuel consumption in the case of the gas-producer has been taken at 1·5lb. to 1·25lb. per brake horse-power hour plus an allowance for stand-by losses. The fuel consumption for the steam-engine has been taken at 4lb. and 3·5lb per brake horse-power for the lowest and highest powers, assuming an evaporation of 8lb. of water per pound of fuel.

Mr. G. WILKINSON (Harrogate) stated his regret that it should be necessary to purchase the Diesel engine abroad, and that there were no firms in England who had taken up its manufacture.

Mr. MICHAEL LONGRIDGE (Manchester) pointed out that improvements were still required, but considered that, even in its existing state of development, the Diesel engine presented very considerable advantages.

Prof. ARNOLD LUPTON (Leeds) said that, admirable as the engine might be, it would never be largely employed as a substitute for the steam-engine, whereas the gas-engine might be so substituted. The chief interest of the Diesel engine, in his opinion, was to be found in the slow combustion.

Prof. GOODMAN (Leeds) thought that the Diesel engine must be regarded as a great triumph for scientific men. The chief reason for the fact that it gave better results than the ordinary gas-engine was to be found in the complete combustion of the fuel. He expressed the wish that English engineers would pay more attention to careful trials of oil-engines. England ought not to be behindhand in this matter, and if Germany could produce an engine such as that under discussion, surely we could do equally well if the effort were made.

Mr. J. MACLAREN (Leeds), Mr. MARK H. ROBINSON (Rugby), and Mr. ALFRED SAXON (Manchester) took exception to various figures relative to the comparative cost of power productions.

Mr. C. DAY (Glasgow) pointed out that the Diesel engine had been made both in England and Scotland, but manufacturers had taken up the invention before it had been completely developed by the patentee. The position, therefore, was that the licensees were placed in an undesirable position. Since the engine had been improved a firm in Scotland had taken up its manufacture, and during the latter part of 1902 had completed an engine for their own use, the results of tests being very similar to those quoted by Mr. Ade Clark.

In replying to the discussion, the AUTHOR said that while the price of the Diesel engine was high, the cost

Digitized by Google

would no doubt be reduced, and that the cost of fuel for the ordinary oil-engine would be three times that necessary for the Diesel type.

A New Form of Friction Clutch.

In opening this subject, Prof. H. S. HELE-SHAW said that the importance of the friction justified a very careful consideration of the problem, and as to whether, in view of the modern developments of motive power, particularly in internal-combustion engines and of high-speed machinery of great power, there were not yet improvements possible. The following is a brief abstract of the paper. The four conditions which seem to be involved in the problem of

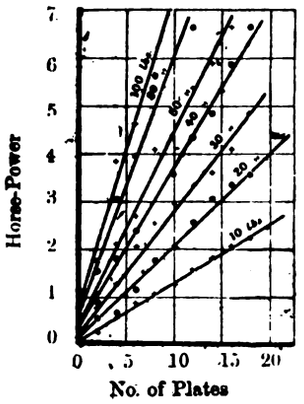

FIG. 1.—Power ransmitted, using various pressures.

the friction clutch are: (1) it must have sufficient gripping power; (2) undue wearing of the surfaces must be avoided; (3) provision must be made for conveying away the heat where there is much slipping contact in the clutch; (4) motion should be imparted to the driven shaft without shock.

The author does not remember seeing in any previous writings on the subject, or in the statement of inventors themselves, the important fact mentioned in condition (3), but it certainly does account for the large number of instances in which friction clutches have failed to give satisfactory results for anything but the smallest powers.

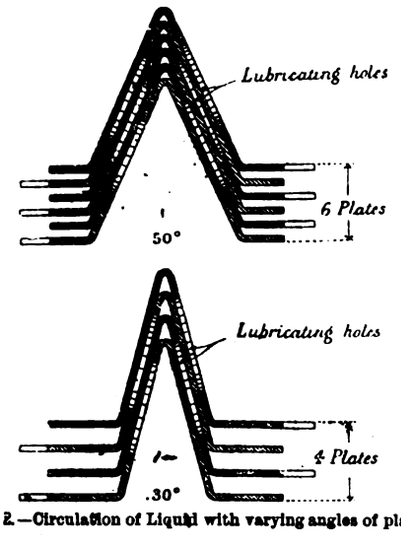

FIG. 2.—Circulation of Liquid with varying angles of plates.

No cluches appear to have been designed for the purpose of allowing slipping to take place to any considerable extent, so as to prevent, at the same time, undue wearing and heating of the friction surfaces. Some devices, such as the coil clutch, the "Weston" clutch, and the expanding ring clutch, may be made to transmit great powers; but it may be safely said that not one of the foregoing clutches has yet been designed so as to be capable of slipping for more than a very short time without being seriously injured, even if the surfaces in contact were not actually destroyed.

There are plenty of illustrations in mechanical science where it has hitherto been impossible to reconcile conflicting conditions, and it is an important question whether the present case forms another example or not. The author believes there is a way out of the difficulty, and this way he indicates in the present paper. Suppose a sheet of metal is pressed into a frustum, the section of the corrugation being the frustum of a cone, and that the disc is placed upon another one similarly corrugated. It will be observed that not only do portions of the frusta not make contact with each other, but there is also a space left between the flat portions of the discs. By placing these discs together, and turning one alternately to the other, an amount of friction is produced which depends on the acuteness of the angle of the frusta. If a number of these plates are now placed in a box of the type of the "Weston" coupling, so that the plates alternately engage with two sleeves, one connected with the driver and the other with the follower, it will be found: first, there is a very considerable gripping power; second, there is a tendency to part rapidly with heat, owing to the

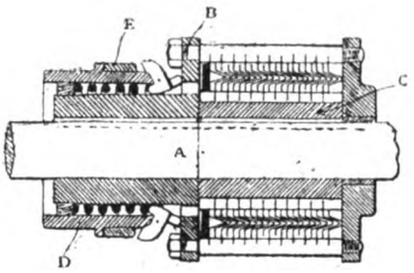

FIG. 3.—Type of Open Clutch, with air cooling.

separation of the discs of metal. By the ordinary theory of friction, the former effect will be found to be much greater, and yet this cannot be accounted for by the ordinary laws of friction, since the increased effect of the wedge action is directly in proportion to the diminution in the number of plates which it is possible to put in a box, which diminution varies according to the same law. There is, however, a still more striking difference between the gripping action of the flat and corrugated plates when a lubricant is introduced.

It may be interesting to give a series of results which have been obtained by actual experiments with a dynamometer attached to an experimental reversing clutch, on the effect of multiplying a number of plates, and gradually increasing the pressure. Fig. 1 shows the results of this series of experiments represented so as to give the horse-power for any number of plates with varying pressures.

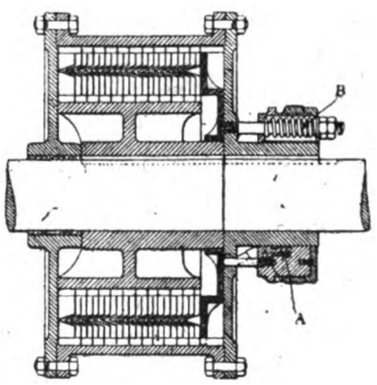

FIG. 4.—Type of Enclosed Clutch.

Efficient lubrication of the surfaces in contact is ensured by drilling the faces of the plates, as indicated in Fig. 2 It will be noticed from this illustration that the number of plates in a given space depends upon the angle of the corrugation, four plates with 30deg. occupying the same space as six plates with 50deg. These four plates give a better grip than the six plates with 50deg., and allow a freer circulation of liquid. The plates are also more rigid with the more acute angle. A standard type of open clutch for shafts up to 2in. diameter is shown in Fig. 3. The shaft is divided at A, the outside case, B, being keyed to the left-hand piece of shafting, and driving the set of plates having external driving teeth, the core, C, keyed to the right-hand shaft, driving the plates with

Digitized by Google

internal driving teeth. Pressure is applied to the plates as follows: The sliding sleeve, D, containing a coil spring, is fitted with pins which project through the outside case of the clutch; these pins press against a flat disc, which in turn presses against the plates, causing the clutch to drive. When the operating lever is worked so as to release the plates, the ring, E, encircling the sleeve withdraws the trigger pins from the holes into which they fit; the spring pressing on the opposite end of the trigger pin causes the trigger to fly up, and the clutch is thereby kept out of operation. By moving the lever so as to force the ring, E, against the trigger, the pin end falls into the hole opposite to it, and the coil spring is then allowed to transmit its pressure to the plates. Fig. 4 shows a section of a larger type of closed clutch fitted to a 3in. shaft, the action of this clutch being similar to that described in Fig. 3. The triggers, however, are worked by separate coil springs, A, the pressure being applied to the plates by means of separate springs, B. A considerable amount of lubricant can be contained in this clutch owing to the construction of the casing.

Applied as a dynamometer the corrugated surfaces are quite successful. Fig. 5 shows one fitted to the 150-h.p. triple-expansion engine at the engineering department, University College, Liverpool. This dynamometer, which replaced one of the Froude type previously used, consists of 40 plates, the corrugations including an angle of 35deg. A is the engine shaft on which is keyed a slotted core, this core driving one set of plates; the outer casing, B, is stationary, it is slotted inside its periphery, and carries the stationary plates. Bolted to this casing is a wrought-iron arm, this arm being connected at its free end to a calibrated steelyard, on which the torque is read off in foot-pounds. Above the dynamometer proper a tank, C, is fixed containing the cooling and lubricating solution. Circulation through the dynamometer is maintained by gravity; the cool liquid enters the casing at D, and, becoming heated, returns to the tank above by means of the pipe, E, fixed to the top of the casing. Inside the cooling tank a coil of piping is arranged through which water from the town mains is allowed to flow by pipes; by this means the arrangement is kept cool for tests of any duration. Varying pressures can be applied to the plates by means of the hand-wheel and screw fixed to the end of the lever, F, the fulcrum being at G. The other end of this lever carries a claw, which transmits the pressure to the ring, H, carrying the pins, which press against a flat disc, this disc transmitting its pressure to the corrugated plates. As each pair of plates have flat springs inserted between them the engine is enabled to run quite free when starting. A friction dynamometer of this type of 600 h.p. has been constructed for Messrs. Vickers, Sons, and Maxim, Barrow. It may be pointed out in connection with these dynamometers that the speed can be reduced to a very low number of revolutions under the conditions of pressure at the engine without impairing the accuracy of the observations, while the running remains perfectly steady for very great loads. Although this dynamometer has been at work for many months, the plates have not worn to any appreciable extent.

A number of applications of the clutch have been already made, but the application which really led to its invention was in connection with the motorcar. There are many cases, such as the use of electricity with petrol motors on light railway wagons, and also with what is called the petrol electrical car, where expensive means have hitherto been employed to effect what can be done in a perfectly simple manner by a slipping clutch such as that described.

Prof. Hele-Shaw's paper was followed by a practical demonstration of the working of the new clutch in reversing gear. With the aid of a motor lent by the Leeds Corporation for the purpose of supplying the gearing with motive power, members were able to see the new slipping clutch in actual operation.

Prof. ARNOLD LUPTON (Leeds) remarked that the friction clutch described by Prof. Hele-Shaw seemed to be what the mining world was wanting. Such a beautifully-arranged clutch as that would enable them to vary the speed at difficult turns in an underground road without altering the speed of the electric motor, and would confer great advantages on all connected with mines.

Mr. WILSON HARTNELL (Leeds) said the clutch supplied what was wanted for electric cranes when they wished to lift very slowly at first, and afterwards at a higher rate of speed.

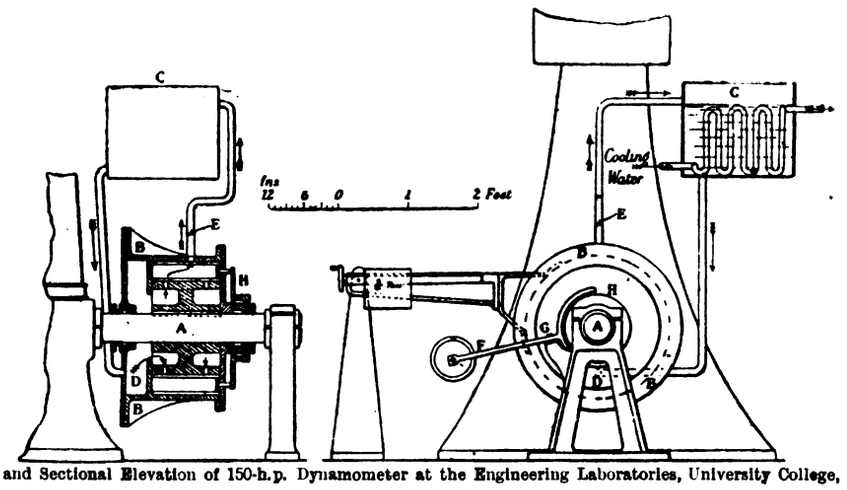

FIG. 5.—Front and Sectional Elevation of 150-h.p. Dynamometer at the Engineering Laboratories, University College, Liverpool.

Mr. BARNES (Liverpool) said the new clutch was one that was bound to have a great effect upon every branch of engineering in which it would be used, and it was hard to say for which branch it would not be suitable.

Prof. HELE-SHAW, replying on the discussion, said the new clutch would doubtless be applied to machine tools in course of time. He had no doubt that this or some other form of slipping clutch was absolutely necessary for the introduction of a chain drive. A chain drive was impossible if you expected a chain to last at all where you had not some "give," when motor and driving machines were put in connection with each other.

Economy of Fuel in Electric Generating Stations.

Mr. HENRY MCLAREN, of Leeds, contributed a paper on this subject, the following being some of his chief points. The first feature that attracts attention in the yearly return of public or municipal lighting authorities is the great difference in cost per unit generated. The generating stations are located in various parts of the country; some are condensing, others partly condensing or non-condensing stations. The price paid for coal varies largely, and different systems of supply are used. All these considerations affect the costs. In the returns for the lighting stations the figures are based on units sold to consumers, and therefore include the large leakage or loss in the mains, which is debited to the generating plant. This may be as much as 20 per cent, and is a very important factor to be kept in mind when comparing purely lighting stations with tramway or railway plants—that "meter" the current as it leaves the station. Engineers would naturally expect that condensing stations would show a better fuel economy than non-condensing stations both for tram and lighting purposes, but so far as lighting only

Digitized by Google

is concerned it is just the reverse. The average, both in fuel and works costs, is considerably in favour of non-condensing stations. Where trams are added to lighting, the condensing plants show a better economy than non-condensing, but in all cases the partly condensing station is the most economical both in fuel and works costs. It is manifestly unfair to compare purely lighting stations, which have only a poor load factor, with stations that combine lighting and tramways, and generate large quantities of current all day long, and meter it as it leaves the station. The author has, therefore, sub-divided the stations given in published tables of costs, and arranged them as follows :

Twenty-Two Metropolitan Stations, Lighting only.

	Units sold.
Non-condensing	24,014,141
Partly condensing	11,305,581
Condensing	41,318,891

as compared with the metropolitan stations, and their average cost of producing current is 18 per cent. less. Here, again, the non-condensing and partly condensing stations are more economical than the condensing, the saving in works costs being 14 per cent. and 16 per cent. respectively, and the saving in fuel 12½ per cent. and 20½ per cent.

Thirty-Two Provincial Stations, Supplying Current for both Lighting and Tramways.

	Units sold or generated.
Non-condensing	7,968,426
Partly condensing	30,040,162
Condensing	39,893,928

In these stations the condensing plants are found to be more economical than the non-condensing by about 9 per cent in works costs and 19 per cent. in coal, but the partly condensing stations are still better than the condensing, showing an economy of 23 per cent. in works

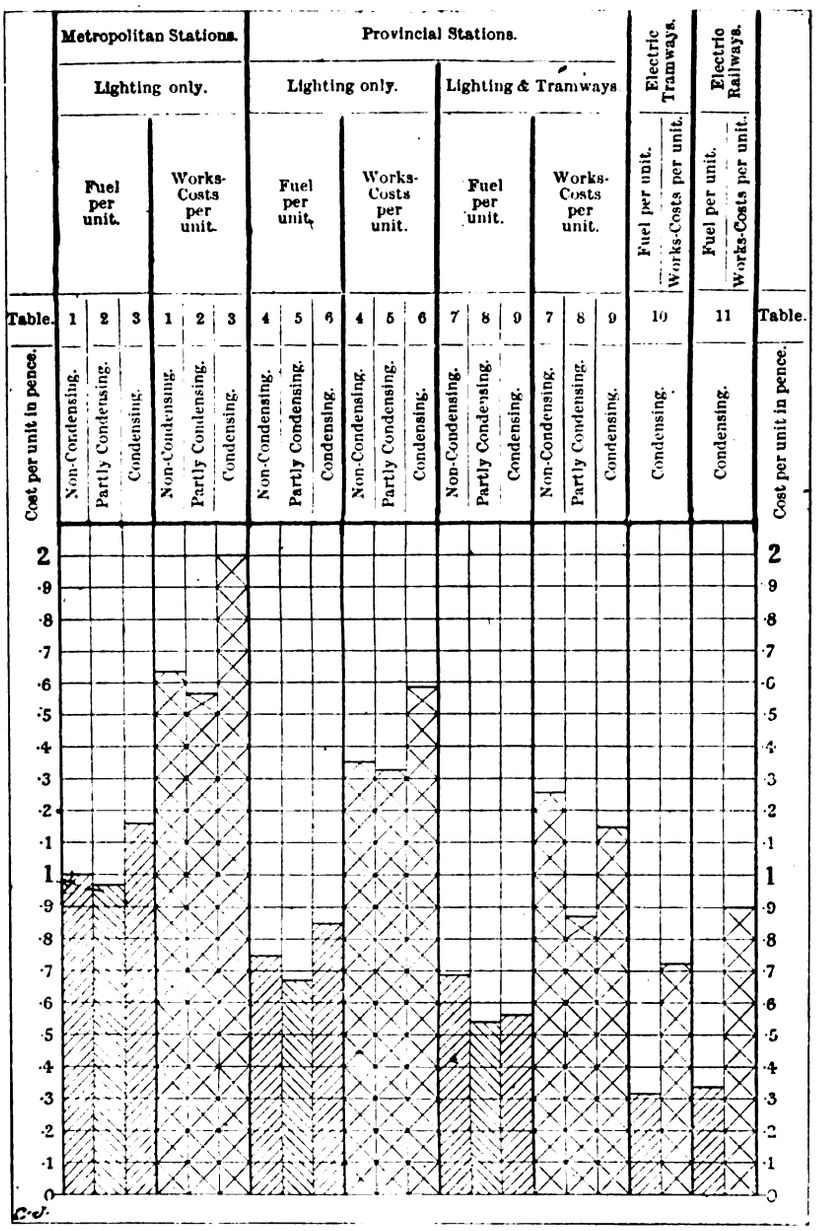

FIG. 1.

In comparing the costs of these three types, it is found that the non-condensing stations produce current at 18 per cent. less cost than the condensing stations. For fuel only, the saving in favour of non-condensing and partly condensing plants is about 14 per cent. and 17 per cent. respectively.

One Hundred and Sixteen Provincial Stations, Lighting only.

	Units sold.
Non-condensing	18,430,119
Partly condensing	20,873,145
Condensing	35,933,215

On the whole these stations have cheap coal and labour costs and nearly 4 per cent. in fuel. It is surprising to find that at least two of the lighting stations, Leeds and Edinburgh, deliver current at the consumers' meters at 9 per cent. lower average cost than averaged at the switchboards of the tramway power stations of Blackpool and Fleetwood, Dublin, Glasgow, and Hull. Glasgow, the most economical of these four power-houses, with an annual output of over 10,000,000 units and a tramway load factor, delivers current at the switchboard at a cost of 0·6d. per unit works costs; whereas the Leeds lighting station, with only 3,000,000 output and a lighting load factor, shows a works costs of 0·62d. per unit, including

Digitized by Google

the heavy loss in the mains. Three power-houses, generating current for the Central London Railway, the City and South London Railway, and the Liverpool Overhead Railway, are beaten in economy by the tramway power-houses already mentioned by over 20 per cent. in works costs and 5¾ per cent. in fuel costs. Fig. 1 shows in graphic form the average costs of the various classes of stations or power-houses. From figures quoted by the author it would appear that the metropolitan condensing stations, after allowing 30 per cent. for outside losses and banking fires, etc., were using at least twice the amount of fuel that economical plants ought to require. They generated during the year over 41,000,000 units at a cost for fuel of over £200,000. A very large percentage of this amount could have been saved by the use of well-managed economical generating plant. It must be remembered that most of these stations were pioneers in the electric lighting industry of this country. Each extension was, in a measure, a large experiment. They have had to contend with difficulties too numerous to mention, and, could their engineers start afresh, there is no doubt that these stations, with their enormous output, would take their place amongst the most economical in the country. Taking the average station throughout the country, there is room for great improvement; on the other hand, one finds a few stations that leave nothing to be desired.

Separate condensing plants are used in most lighting stations. The vacuum in the main engine low-pressure cylinder is usually poor owing to the long lengths of exhaust pipe, often overcharged, and having numerous sharp bends. Engines fitted with their own condensers have a great advantage over those exhausting into one main serving several engines. Usually a saving of 5 to 10 per cent., due to the better vacuum, is effected. Add to this the 10 per cent. of steam used by the separate plant, the loss in the auxiliary steam-main with its traps, the loss in starting up separate plants for short runs, the loss at light loads, the loss of vacuum through leaky atmospheric exhaust valves, and it is not so surprising that under these conditions the economy due to condensing reaches the vanishing point, or even falls behind well-equipped non-condensing stations. It is rather remarkable that the partly condensing stations show the best average economy. "Partly condensing" is a very vague term, and no doubt most of them might be classed as condensing stations. Without exact data it is impossible to come to any definite conclusion as to the reason.

Statistics show that in lighting stations the non-condensing engines beat the condensing by 13 per cent. in fuel economy. This is the average over the whole country, 13 + 25 = 38 per cent., to be accounted for to bring matters as they ought to be. Uneconomical three-crank, compound, tandem, condensing engines, largely used in lighting stations, no doubt account for some of this, and, as already shown, separate condensing plants are also steam wasters. All non-condensing stations should be fitted with efficient exhaust steam feed heaters. Feed heaters or economisers fixed in the boiler flues cool the waste gases, and to a certain extent spoil the draught. The best results are to be got by employing both types of heater, the water entering the economiser at nearly boiling point.

The steam losses in electric generating engines are mostly due to valve or piston leakage. Unless engines fitted with piston valves are very carefully looked after, heavy leakage is likely to occur. Many station engineers do not realise how serious this loss may be, and allow their piston valves to run in a very leaky condition. Balanced slide valves and valves of the Corliss type, having some pressure on the back to keep them up to the port faces, require much less attention, and will run for many years practically steamtight.

Two recent tests of condensing engines fitted with piston valves, disclosed the fact that they required over 40lb. and 50lb. of steam per kilowatt-hour respectively. When previously tested the consumption was about 30lb. per kilowatt in each case. Outwardly they appeared to be running as well as ever. It is safe to assume that £100,000 was lost during the year ending March, 1902, in engine leakages alone. There is no doubt it would pay to employ an engineer in each of the larger stations to do nothing else but make tests and report on fuel losses with a view to their remedy.

Engine builders find much less difficulty in getting their guarantee figures from the honest steam of the Lancashire or other cylindrical boiler than they do from the high-pressure "Scotch mist" given off by the now fashionable box of water-pipes. In lighting stations there are great fluctuations in the demand for steam. Only those who really understand the art of firing, can appreciate the difficulty of working mechanical stokers with economy under such conditions. An efficient method of forced draught is a decided advantage in lighting stations, if it is properly used, for it enables steam to be maintained over the peak of the load. The latest system of Halpin's thermal storage is the ideal method of obtaining the same end. At light loads the steam-jet method of forcing draught is often greatly mismanaged. A peep through the small side door at the back of the grates, in a Babcock boiler, fitted with moving grates and forced draught, and carrying, say, half-load, is often a revelation of how not to do it. One third of the grate may be covered by a spouting volcano of fire, the remainder employed in carrying away dead ashes and clinker, allowing large quantities of cold air to pass, all of which has to be heated up to the temperature of the escaping gases. Under these conditions a low flue temperature is no criterion of economy.

Some makers of steam-jet draught producers only require 3 per cent. of the steam generated to supply their blowers; others state that they require 3 per cent., but their fittings are found to be large enough to pass four times that amount, even when the full rating of the boiler is taken. Feed pumps and other boiler house auxiliary engines require a considerable percentage of the steam generated. In condensing stations better economy is obtained by utilising the exhaust of the auxiliary engines in heating the feed than by working them as condensing engines. In lighting stations the losses in the ring steam-main, with its numerous traps, is a serious consideration. It is seldom less than 5 per cent., and may be very much more if the traps are not kept in perfect order and properly regulated. Superheating, especially when piston-valve engines are used, shows a good steam economy, but the saving in fuel is not so marked, and in lighting stations its proper regulation is rather difficult. The extra wear and tear on the main engines and on the superheaters themselves are items that have to be considered. The station engineer should note that the average works costs for the non-condensing lighting stations are 16½ per cent. less than the condensing stations. One explanation of this may be that less plant requires less looking after and less repairs. But a well-managed condensing station with economical engines is certainly the most economical type of station, especially where trams are coupled with lighting.

There are only four stations given in the tables wholly using steam-turbines—Newcastle, Scarborough, Cambridge, and Melton Mowbray. Newcastle station is the lowest both in coal and works costs, yet it is easily beaten by South Shields, a station with vastly less output, situated on the same river, and using triple-expansion condensing engines, which comes out 35 per cent. less in fuel and 25 per cent. lower in works costs than the turbine station. Northwich, using Mond producer gas, has an output of 104,000 units Its fuel cost is 0·48d. per unit; works costs are 1·48d. per unit. This is handsomely beaten by Leigh, a station with a smaller output, using non-condensing steam-engines, which comes out at 28 per cent. less in fuel and 15 per cent. less in works costs. Redditch, the other gas-engine station, using Dowson producer gas, has an output of over 172,000 units; coal costs are 1·3d. per unit, and works costs are 2·61d. per unit. There are over a dozen smaller-sized steam-engine stations that beat these results. It is encouraging to note from recently-published returns that the costs in various stations throughout the country show a decided tendency to improvement. This is partly owing to cheaper coal, but there is also a healthy rivalry between station engineers which should in time bring the electric generating stations into the front rank as regards economy of fuel.

Digitized by Google

In the course of the discussion which followed, Mr. GEORGE WILKINSON (Harrogate) said he would like Mr. McLaren to give them the names of the condensing stations which lowered the averages so much that they compared so unfavourably with the non-condensing plant. He himself thought that condensing stations were as efficient as non-condensing plant.

Mr. CHARLES FORGAN, one of the engineers connected with the Central London Railway, spoke of the relative cost of hand and mechanical stoking. Some time ago his company decided to make a change from mechanical to hand stoking, and after six months' running the cost of coal worked out at £4,000 a year less than under the system of mechanical stoking. He could not believe that all this reduction was due to the stoking.

Mr. J. D. BAILIE (Leeds) regretted Mr. McLaren had spoken disparagingly of the steam-turbine stations. He considered that it was unfair to compare the station at Newcastle, which had been in operation many years, with a new station like South Shields.

Mr. T. L. MILLER (Liverpool) regarded the alleged superior economy of non-condensing stations over condensing stations as the most interesting point of Mr. McLaren's paper. His own view was that non-condensing engines were the least economical.

Mr. MARK ROBINSON (Rugby) said that there was no need to wonder that the non-condensing station came out the best with a lighting load. For almost any purpose a partly condensing station was likely to be the best. Referring incidentally to the late Mr. Willans, of Leeds, he remarked that that gentleman nearly 20 years ago made non-condensing engines which used 18½lb. of steam per indicated horse-power, the same engines using about 12½lb. when working condensing.

Mr. MICHAEL LONGRIDGE (Manchester) said: "Electrical engineers have shown us how to measure, how to measure accurately, and how to record results, but I think that in the choice of their plant and steam-engines they have still a good deal to learn." One reason why the non-condensing engine had come out more economically than the condensing engine was that on the whole condensing engines were very badly designed. He urged every engineer to put a condensing plant to his engine.

Mr. A. SAXON (Manchester) remarked that a cotton mill in Lancashire could be run with an engine which developed 1,000 h.p. for £20 worth of coal per week, running 56 hours per week. That included the steaming and heating of the rooms and stand-by losses.

Mr. MCLAREN, in the course of his reply, said that recently his firm put in a new engine and thereby effected a saving of 60 per cent. in fuel. If it had been a motor, the saving would have been credited to electricity, but as it happened, the engine had nothing to do with electricity.

ELECTROLYTIC APPARATUS.*

BY F. MOLLWO PERKIN, PH.D., MEMBER.

Owing to the great expense of platinum and the necessity for its use in electrochemical analysis, members may be interested in the description of a simple form of electrode, which is comparatively inexpensive and is very satisfactory.

In Fig. 1, which shows the electrodes, the cathode is in the form of a flag and is made of platinum gauze, which is held rigid by means of a platino-iridium frame (10 per cent. iridium); the frame, which is roughened by means of the sand blast, has a stout piece of iridio-platinum wire welded on to it. The wire, of course, is for holding the electrode in position during analysis. The loop near the top of the wire is for hanging the electrode on the balance. The anode is made of iridio-platinum wire, and is bent upon itself in such a way that when it is placed into position for electrolysis, as illustrated in Fig. 2, an even current density is obtained on all parts of the cathode. The distance between the two sides of the anode is 2·5cm., therefore, when in position, it is 1·25cm. distant from each side of the cathode.

The cathode is 6cm. high and 4·3cm. wide, and the length of the supporting wire is 7·5cm., the loop being 2·5cm. from the end. As the anode is opposed to both sides of the cathode during electrolysis, it follows from the above measurements that the total cathode surface is 50·4 cm.², that is, practically half a square decimetre, which, as the C.D. for analytical purposes is generally calculated per square decimetre of surface, is a very convenient size. It is not essential for the cathode to be made of gauze—in many cases sheet platinum is quite as useful; but for metallic deposits which are inclined to exfoliate—such as bismuth and antimony—the gauze is more satisfactory; it is also very useful for mercury and for peroxide deposits. The gauze should not be too fine; the finest which I have found satisfactory is about 50 to 60 meshes to the square centimetre.

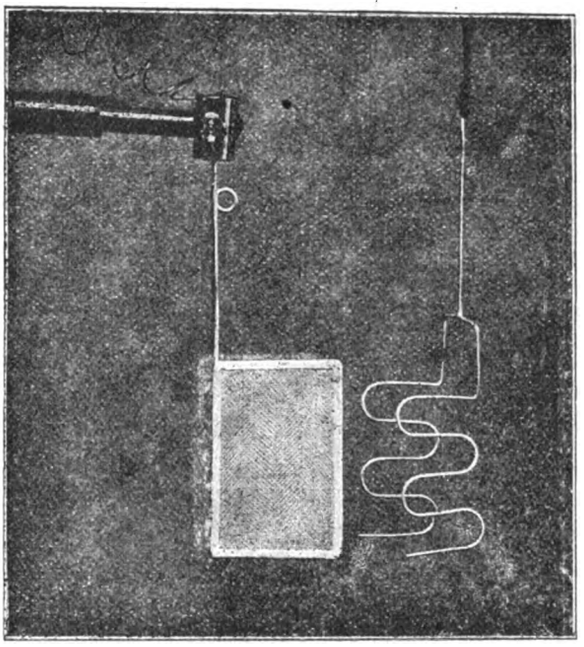

FIG. 1.

When it is too fine there is a tendency for hydrogen to collect upon the surface and thus cause polarisation.

The weight of the cathode, when made of platinum sheet, is about 14·5 grm. If thinner platinum is employed the weight can be reduced to 8 grm., but I have found it better not to make them of very thin platinum, because then they are so fragile and there is a tendency for the deposits not to adhere well at the edges. The weight of the gauze electrode is about

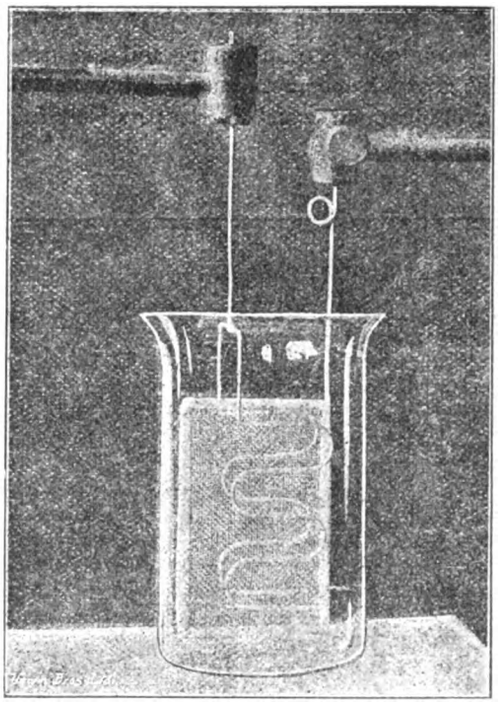

FIG. 2.

15 grm. It follows that, as these electrodes weigh much less than the basin or cylinder ones, they are much cheaper. A basin usually weighs from 40 grm. to 60 grm., and a cylinder from 26 grm. to 28 grm.

These electrodes are also more satisfactory for carrying out electrolytic separations, the manipulation being much easier than with the basin. Suppose, *e.g.*, that one is electrolysing a mixture of copper and iron salts. In the first place, the copper

* Paper read before the Faraday Society.

Digitized by Google

would be deposited out from an acid solution; then, after neutralising, the iron would be electrolysed out. Now, when a basin is used, the solution has to be transferred to a beaker, and as the manipulation has to be rapid there is a danger of loss through spilling; further, the acid solution must not be left in contact with the copper deposit. The dish, therefore, must be washed at once, and the solution which is clinging to its sides, and which contains iron, is lost. In the case of the

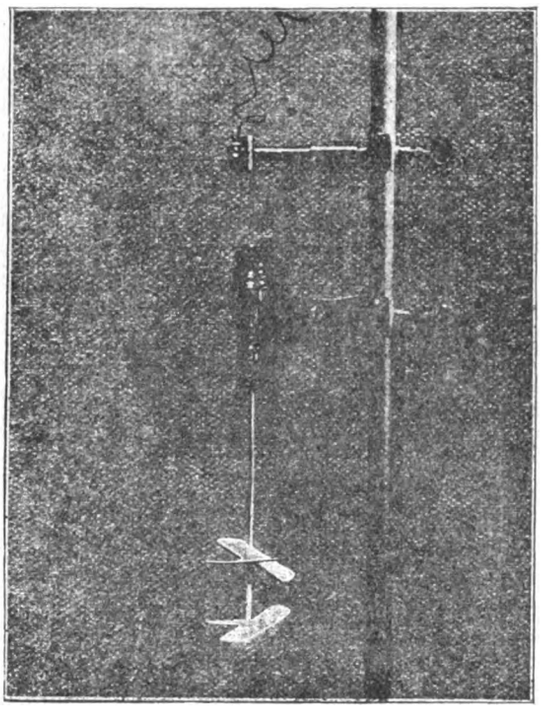

FIG. 3

flag electrode the cathode is rapidly raised out of the beaker and the solution at once washed off its sides while it is hanging over the top of the beaker by means of a wash bottle. The solution in the beaker can then be neutralised without being transferred to another vessel; multiplication of manipulation is thus avoided.

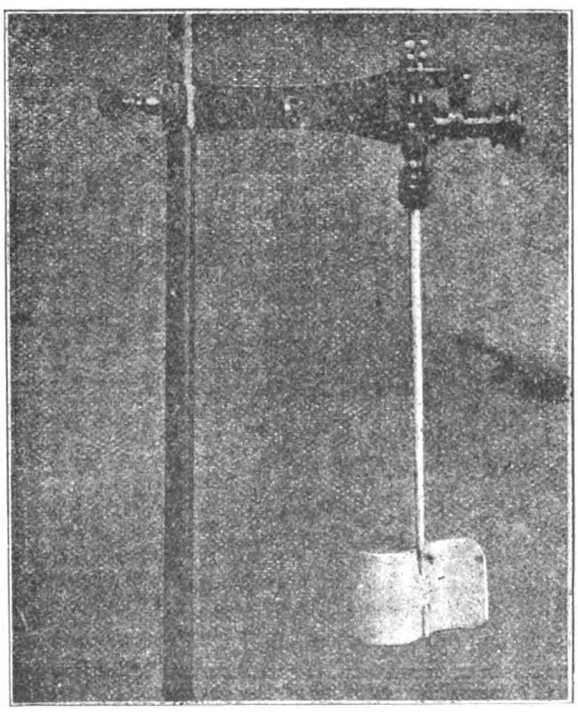

FIG. 4.

Apparatus for Rotating Electrodes.—It is often necessary in electrolysis to keep the electrolyte agitated. This is generally done by means of an agitator, entirely separated from the electrodes and rotated by means of a water turbine or motor. In many cases, however, much better results are obtained if one of the electrodes is itself caused to rotate. In most of the descriptions of rotating electrodes, there seems to have been considerable difficulty in obtaining good electrical contact, and the methods employed have often been rather complicated. Fig. 3 shows an arrangement which has been found to work extremely well. It consists of a supporting arm, made of gun-metal, the end of which is drilled to allow a spindle to pass. This spindle carries a small chuck (such as is used for fixing small drills on a lathe), which is used for fixing the rotator. The grooved pulley, which is fastened on to the upper end of the spindle, bears on the top of the arm, which is ground smooth. The whole arrangement is driven by means of a belt from a water turbine or electrical motor. This arrangement is found to give very perfect contact and to work with very little friction. The parts should only be slightly lubricated, the best lubricant being a mixture of graphite and vaseline. The water turbine, which has proved very useful, and has been working for a long time, has ball bearings—an unusual nicety—and was obtained from Messrs. Baird and Tatlock, Glasgow.

Fig. 4 shows another form of the rotator, which can be driven either from a horizontal or vertical pulley, and is also convenient for working several apparatus in series. The electrode shown in Fig. 3 is of iridio-platinum, and has been used with very satisfactory results in the electrical oxidation of organic substances. The electrode in Fig. 4 is of aluminium.

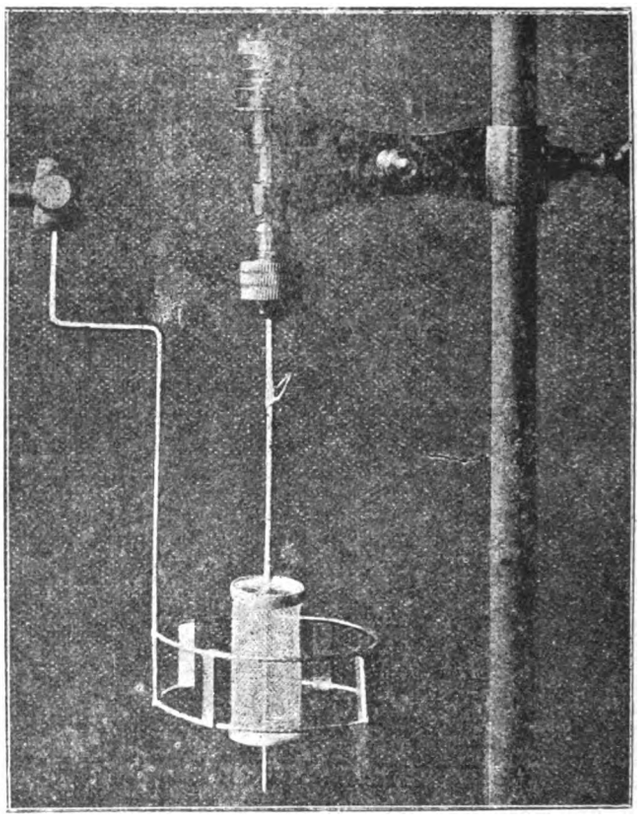

FIG. 5.

I have found the following method work very well for making rotating lead electrodes. Thin lead pipe, to which the vanes for mixing the liquid are burned, is drawn over a steel rod of the same diameter as the bore of the pipe. The steel rod protrudes about 1in. above the top of the pipe, in order that it may be fastened in the chuck. The pipe is burned at the bottom and the top to prevent the solution from running in between it and the steel core. If a central core such as this is not used, lead electrodes are not sufficiently rigid to use for rotating purposes.

Rotating Cathode for Analysis.—In Fig. 5 is shown a rotating cathode and a stationary anode for electrolytic depositions. It is found that the rate of deposition of a metal from its solutions is very much accelerated, and that a higher C.D. can be employed when the cathode is kept in rapid motion. The cathode is a small cylinder of platinum gauze, which has a combined surface of about 25cm.^{2} The anode, B, is in the form of a double circle of stout platinum wire, and has four little baffles placed at intervals round it, to prevent the liquid from rotating with the cathode. Of course, for peroxide deposits the rotating electrode would be the anode. A cylinder of sheet platinum also gives very good results, but in this case very little metal is deposited upon the inner surface. Longitudinal slits, however, partially get over this difficulty, but with gauze, as shown in the figure, the deposition is practically equal inside and outside.

NOTES.

Books Received.—"Electrical Engineering" (Crosby Lockwood and Son), by Tyson Sewell, A.I.E.E., 7s. 6d.; "The Engineer in South Africa" (Archibald Constable and Co., Limited), by Stafford Ransome, M.I.C.E., 7s. 6d.; "The Art of Illumination" (McGraw Publishing Company), by Louis Bell, Ph.D., 10s. 6d.

German Electrical Industry.—There seems to have been a revival of the electrical manufacturing industry in Germany within the last six months or so. Official returns show a noticeable falling off in the importation of foreign electrical machinery into Germany, the figures for the five months ended May 31 last giving a total of only 322 tons, as contrasted with 634 tons in the corresponding period of last year. Also, there has been an increase in the exports of electrical machinery from Germany. The total for the first five months of the present year was 5,158 tons, while that for the same period of 1902 amounted to 4,899 tons.

Electricity as a Disinfector.—An Italian scientist claims to have established that electric tramways are great mediums in the disinfection of towns. He points out that the electric spark, which is so frequent an occurrence to the overhead trolley, and the emission of light from the car wheel when the rail is used for the return current, transform the oxygen of the air into ozone, which has a purifying and disinfecting influence. The high discharges, he says, are frequent enough to influence greatly the atmospheric constituents, especially where the line passes through narrow thoroughfares. They become antiseptic agents.

Long-Distance Tramways.—Last month there was put in operation for the first time in the States an electric tramway or street railway which has a length of 188 miles. It runs between Indianapolis and Columbus, the capitals of two contiguous States. Originally the line was worked in sections—that is to say, the through route has been obtained by completing the gaps in the chain of interurban lines between the two cities in the same way as the various electric tramway systems in Lancashire in this country are being joined up by the South Lancashire Tramways Company. A line is soon to be completed from Newark to Lanesville, which will carry the through route on another 100 miles or so to Wheeling.

Electrolytic Reduction of Unsaturated Acids.—When a solution of aconitic acid, to which half the quantity of sodium hydroxide necessary for complete neutralisation has been added, is electrolytically reduced, using a cathode of mercury and an anode of platinum, and an apparatus designed to prevent as far as possible oxidation at the anode, a yield of 60 per cent. of the theoretical quantity of tricarballylic acid be obtained. Such is the conclusion drawn by Mr. Ch. Maril from a series of experiments on the subject. The acids were separated by conversion into their copper salts, that of aconitic acid being soluble in dilute acetic acid. Cinnamic acid can by this method be converted quantitatively into phenylpropionic acid.

Smoke Helmets for Tube Railways.—One lesson of the recent disaster on the Paris Metropolitan Railway is to emphasise the importance of a special fire helmet for irrespirable atmospheres. It seems that a helmet of the kind has been designed, and the Paris Municipal Council have voted £120 for the manufacture and experimental use of a number of helmets in the principal stations. The helmet consists of a glazed circular headpiece surmounted by a small chamber containing an air pump, a vizor to protect the face, and with the air pump are connected two tubes—one for inspiration and the other for expiration, and merging in an indiarubber pipe connected with an air compressor near the spot to be explored. Three men are necessary, one to penetrate into the choke area, the other to hold a safety lamp, and the other to work the air compressor.

Brazil Rubber.—There is a good prospect that the yield of rubber in Brazil for the current year will be bigger than ever, despite the fears that have been entertained that the rubber supply is becoming exhausted. An American consular report from Para assures us that the greatest enthusiasm is being shown in the trade there. The rubber crop for the year 1902-3 closed very satisfactorily, the yield being 29,890 tons. Although this is a decrease of 108 tons on the previous year's produce, it should be remembered that the 1901-2 crop was the largest ever produced. "Never before," says the consul, "have so many men been employed in the business; thousands of labourers are pouring into the forests of the interior, and thousands more are expected to follow. New rubber fields will, it is said, be opened, and old ones worked with improved methods and larger forces." As an example of this, the consul adds that one of the largest producers on the Madeira informed him that he would take out this year four times as much rubber as ever before.

Indian Telegraph Department.—In the last two or three decades the expansion of the superior establishment of the Telegraph Department of India has been on a large scale. This is shown by the following figures. In 1877 there were 423 telegraph offices, and in 1900 this figure had increased to 5,420. In the same way the mileage of telegraph posts increased from 17,232 to 52,909, and that of telegraph wire from 39,113 to 170,776. This expansion has chiefly been in the divisions of the Punjab, Bengal, Bombay, Madras, Assam, and Eastern Bengal, and changes have necessarily had to be made from time to time to meet the growing requirements. Now, however, the Indian Government has taken in hand a scheme of reorganisation, by which five new divisions will be created. The proposals include an all-round increase of staff, and among the appointments will be two under the designation of deputy director of traffic and deputy director of construction. The salaries will be at the rate of Rs.1,600 a month, or, converted into English money, nearly £1,100 a year each.

Hertzian Waves.—It will be remembered that Prof. Fleming in his recent Cantor lectures on wireless telegraphy, emphasised the importance of research in the direction of finding some means of directing the Hertzian waves or of detecting the direction from which they are sent. Mr. R. Blochmann has put forward a possible solution of the problem in a paper before the German congress at Carlsbad. Instead of sending out the electric impulses from tall rods or antennæ, whence they burst out like explosions, or like stones flung into an electric pond and causing electric ripples, he suggests that the waves should be sent out through lenses. A lens of glass or of paraffin wax, or any other substitute of high dielectric constant, will serve the purpose, and that purpose will be the concentration and orientation of the waves in a certain direction. The effect of trains of waves which have thus been directed and concentrated is further enforced by making them traverse a lens at the receiving station similar to that at the sending station, the detector of the waves being placed at the focus of the receiving lens. Mr. Blochmann intends to pursue his researches into the possibilities of this method, which, of course, is as yet only in the experimental stage.

Electrical Fire Rules.—About the present is the time when the various insurance companies are wont to issue revised lists of rules and regulations for electrical installations. This week we have received copies of those issued by the Royal Insurance Company and the Liverpool and London and Globe Insurance Company respectively, and it is with no uncertain pleasure that we find ourselves able to congratulate both companies on following the course laid out for all fire insurance offices by the Institution of Electrical Engineers. Thus, the Royal Insurance Company adopts the Institution rules *in toto*, with the addition of a few special conditions of its own coining; and the same may be said of the Liverpool and London and Globe list, embodying as it does the latest general rules issued by the Institution. We believe this is the first time that the rules drawn up by the Institution have been officially recognised and adopted by the insurance companies, and the course cannot be too highly commended as tending towards complete uniformity in the rules governing electrical installations all over the country. In addition to the general rules, each company attaches a "special risks supplement," which relates to the special conditions to be met with in warehouses, mills, central stations, car-sheds, factories, trolley wires, etc. These are identical in both cases, and the recommendations embodied therein must prove of the greatest value to those responsible for carrying out electrical installations on premises to which they apply.

Abyssinian Telegraphs.—The Emperor Menelik is ranking his country very closely with many European States in the provision of telegraphic and telephonic facilities. For some years both the telegraph and the telephone have been in operation between the towns of Harar and Addis Abeda, and recently the seat of the Government of Abyssinia has been connected by telegraph with Jibuti. An estimate places the total length of the telegraphs in the empire at 500 miles. Acoording to a statement made by the director of the telegraph line from Massowah to Addis Abeda, Eritrea and the capital of the country will shortly be in communication. This will increase the total length of the line in use to 1,060 miles. A telephone system now connects Asmara with Barromeida by way of Adowa, and Addis Abeda with Ankober. The Emperor has given permission to the Italians to construct the line from Massowah on condition that it passes by Ankober, where the political prisoners of Abyssinia are detained. Menelik more and more realises the necessity of being quickly informed of what is passing in all parts of his empire. He receives daily reports by telephone. The southern frontier is at present not included in the system, but Menelik has given orders that a telephone line 500 miles long shall be constructed by way of Kaffa. The necessary material has already arrived in the country. A telegraphic line from Wallaga, proceeding in a westerly direction parallel to the Blue Nile, is also contemplated. In a few years Abyssinia will have a complete telegraphic system.

New Theory for Auroras.—Mr. Charles Nordmann has presented a paper before the Academy of Sciences at Paris, in which he suggests that auroras may be due to Hertzian waves emitted by the sun. Experiment proves that, owing to the diffraction of the atmosphere, Hertzian waves, especially of great wave-length, "turn corners," or, in other words, pass around intervening obstacles. The waves of the space telegraph, for example, surmount the intervening convexity of the earth between two distant stations. It is not surprising, therefore, that auroras should be visible in the polar regions during winter, although the ordinary rays of the sun do not reach them. Mr. Nordmann, seeing that Hertzian waves have passed between Newfoundland and England, a distance of about 30deg. on a great circle of the earth, argues that at the equinox polar auroras should be most frequent within 30deg. from the pole, and that has been found the case. It would follow from the above that auroras would be most frequent in the early hours of the night and morning, but another factor comes in. It has been proved that the luminescence of a rarefied gas is brighter the more free ions exist in it. In a small tube the free ions disappear mainly by diffusion, but in the atmosphere by recombination of positive and negative ions. The upper atmosphere is, he thinks, ionised during the day by the violet and ultra-violet rays of the sun, but through the night toward morning there are fewer free ions in the atmosphere, and so the Hertzian waves of the sun do not readily excite luminescence in the atmosphere at that time. The number and intensity of auroras ought, therefore, to be greatest in the early hours of the evening and decrease toward morning.

Wireless Telegraphy in Japan.—Advances in the use of wireless telegraphy in Japan, and particularly in the Japanese navy, cannot, it seems, be laid directly to the credit of Mr. Marconi. That inventor's application for letters patent in Japan some time ago was refused, and the system now in use has been developed by a Japanese scientist. An American consular report from Kobe gives some interesting information with regard to the progress space telegraphy is making in the East. The Japanese warships equipped with wireless telegraph apparatus have sent and received messages to and from Japan at a distance of about 50 miles, and the system is to be further extended at an early date by the Japanese Navy Department. The necessary plant is now being erected for the establishment of communication by wireless telegraphy between Miesaki, in Nagasaki prefecture, and Sharyo Island, off Kelung, Formosa, a distance of about 850 miles. The installation was commenced in January last, and the expenditure on the enterprise is estimated at about £4,000. Mr. Saiki, an engineer in the department of communications, is in charge of operations at Miesaki, and the instruments are now well on the road to completion. The station at Sharyo was commenced in March last, and is in charge of Mr. Ichimura, an engineer in the same department. Experiments with wireless telegraphy, it seems, have been continuously made by the department of communications and by the navy since 1896. The experiments were first made with satisfactory results over a distance of 11 miles, and afterwards between the shore and ships in Tokyo Bay, a distance of over 20 miles. The system of wireless telegraphy employed in Japan is stated to differ materially from the Marconi system.

Electrolysis of Aqueous Solutions.—There is published in the current number of the Chemical Society's *Journal* an abstract of a paper by C. Frenzel, who states that when solutions of ammonia or of the hydroxides of the alkalies or alkaline earths are electrolysed with an unpolarisable cathode and a small anode, a gradually increasing E.M.F. being employed, the curves representing the connection between the current passing and the applied E.M.F. exhibit a change of direction corresponding with the discharge of hydroxyl ions; after this, the current increases with increasing E.M.F., it then remains constant or diminishes, and finally increases again. The E.M.F. at which the second increase begins, varies with the concentration of the hydroxyl ions in the solution; when the latter is divided by 10, the E.M.F. rises by 0·06 volt. The form of curve described above is only obtained when the anode is a platinum wire freshly heated to redness; when the same wire is used repeatedly, the successive curves become more and more continuous,

Digitized by Google

finally exhibiting a steady rise of current with rising E.M.F. The change is much more marked in solutions of ammonia than it is in the other solutions. It is shown that the impurities in the salts used have no effect on the form of the curves, and also that the assumption of a transition resistance at the anode due to a layer of gas does not account for it. The assumption of some chemical change at the anode is therefore necessary. The most probable is the formation of ozone by interaction of discharged hydroxyl ions and molecular oxygen occluded by the electrode. This is capable of explaining the effect of heating the anode to redness, and also the dependence of the position of the change of direction on the concentration of the hydroxyl ions in the solution.

Electrical Schemes in South Africa.—Manufacturers of electrical machinery and appliances in this country should keep a watchful eye on what is doing in South Africa at the present time, especially on those parts which have only lately ranked among the dominions of the Empire. In the Transvaal one of the biggest electrical undertakings South Africa has yet seen is making favourable progress at Johannesburg, but it is only the forerunner of what is to come in the near future. In the past 12 months or so innumerable schemes for supplying electric light and power have been launched, and soon any town in British South Africa which is unable to boast the electric light will be looked upon as behind the times. To mention a few of the schemes that are now going forward, Mafeking—that gallant little town in Bechuanaland of historic memory—has adopted a proposal in favour of the electric light, but beyond the fact that it has been decided to generate by oil-engines, nothing has yet been definitely settled. Manufacturers may also be interested to hear that the Transvaal Tender Board are now calling for tenders for the electric lighting of Potchefstroom, which will be received up to Oct. 30. The specifications and other details will be furnished on application to the Assistant Colonial Secretary for Urban Affairs, Pretoria. As Potchefstroom is a fairly large and growing town, it is likely that the orders for plant will be very considerable. In Natal, the municipality of Harrismith are progressing with their electric lighting scheme as prepared by Messrs. Mordey and Dawbarn, who have been empowered to carry out the necessary work to completion. The tenders will be out shortly, and our readers may expect the orders to be of a fairly extensive character. We gather from the *British and South African Export Gazette* that these are but a few of the electrical schemes which are going forward in South Africa, and there is little doubt but that the field which is now opening to British manufacturers in that country offers vast opportunities, which every day are becoming more extensive.

Australian Patent Law.—Those of our readers who are concerned in Australian patents will be interested in the following information, which has been furnished us by Messrs. W. P. Thompson and Co., of Liverpool, with regard to the provisions of the Australian Federation Patent Bill, which was introduced into the Australian Senate and received its first reading in June. The subject of a single patent to cover the whole Australian Commonwealth has been one of lively interest ever since the Commonwealth became an accomplished fact. The Bill follows in general the British Act, while modifications are numerous and important. The principal provisions may be summed up as follows: patents to be granted for 14 years to cover the six States comprising the Commonwealth; examination as to novelty is to be made to a limited extent; actual working of the invention within the Commonwealth must be begun within five years, and must be continuous thereafter; patent attorneys must be registered; applications for patents may be filed by the inventor or his assignee, by representative of deceased inventor or assignee, or by a communicatee; additional patents are provided for at half fees; compulsory licenses are provided for; existing State or Colonial patents remain without change in their scope. An important and valuable feature is found in Article 57, according to which a patent is valid as to all good claims, notwithstanding it may contain one or more invalid claims. The working requirements cannot fail to appear to an Englishman to be a retrograde step, and it is to be hoped that those requirements will be eliminated. The cost of a patent under this new Bill to cover the six States comprising the Commonwealth will be about one-sixth the cost of taking out patents at the present time to cover the same area. There is, however, a fee of £8 payable before the actual issue of the patent, and a renewal fee of £5 before the expiration of the seventh year. If enacted this session of Parliament, the Act may take effect as early as next January, but it is more probable that it will not come into force earlier than January, 1905.

Wireless Telegraph Conference.—We briefly noted in last week's issue the main conclusion arrived at by the conference which recently considered the question of wireless telegraphy in Berlin, to the effect that it was advisable that all coast stations should be obliged to receive and to forward all telegrams from vessels at sea irrespective of the system employed. We are now able to give several of the other recommendations which were adopted in a general way, which, without binding the Governments represented, will serve as a basis for future discussion. In order to facilitate communication between vessels and coast stations, it is proposed that all technical explanations referring to the working of the apparatus shall be published. Telegrams referring to wrecks and attempts to render assistance to vessels at sea should be forwarded before all others. The rates for telegrams forwarded into the interior from a coast station will be those of the ordinary telegraph service plus a special charge for the use of the wireless apparatus, and will be paid for on receipt. Telegrams sent to a vessel will be paid for on board the vessel at the rates usually charged by the nation under whose flag the vessel sails. Stations are to be arranged so as to interfere with one another as little as possible, and arrangements will be made to ensure correspondence in a number of technical details. Provision is made for other states besides those which sent representatives to the preliminary conference to be parties to any arrangements which may finally be made for the regulation of wireless telegraphy. It will be remembered that the representatives of this country and Italy did not agree to the main conclusion. The reason for Italy's action in this matter is that the Government is bound by a 14 years' contract with the Marconi Company to employ no other system, and can only promise to suggest to the company that alterations should be made in the contract so as to bring it within the terms of the proposed convention. This country's representatives promised to lay the resolutions of the conference before their Government, but refused at the present time to be a party to an international agreement on the lines indicated.

α-Rays of Radium.—Henri Becquerel has published an account of some experiments conducted by him concerning the α-rays of radium. From an abstract in the current number of the *Journal* of the Chemical Society, it seems that a radium salt was placed in a lead tube, and this was closed by an aluminium plate to arrest the light emitted. Above this a screen was placed, and over it a photographic plate lying horizontally, the whole system

Digitized by Google

being oriented parallel to a strong magnetic field. Provided the exposure is not too long, no appreciable impression is produced by the γ-rays. If in the middle of the exposure the direction of the magnetic field is reversed, an impression of two parallel tracks is produced on the plate. If the plate be placed at an angle instead of horizontally, the tracks are curved and meet at the point of contact of the plate and the screen. It might be that these curves were segments of circles in accordance with the ballistic theory. In this case it was to be expected that the relationship $R H = m v/e$ would hold good as it does for the β-rays, where R is the radius of the circular trajectory, H is the intensity of the magnetic field, m is the mass carrying charge e, and v is the velocity. The results obtained for R H when the distance of the plate from the screen is varied are not constant, but vary from $1{\cdot}9$ to $2{\cdot}9 \times 10^5$. This inconsistency may well be explained by variation of the mass, m. It is certain, however, that the curvature of the trajectory of the α-rays increases with the length of the trajectory, and the disturbance is no doubt due to the presence of the air. In a vacuum, R H would probably be constant. If we assume m to be a material mass positively charged, then on passing through the air it attracts the negative ions of the air and the charge, e, diminishes. If m be assumed to be merely an electromagnetic magnitude dependent on e and v, it may likewise be admitted that the charge, e, attracts the negative ions of the air and thus alters the trajectory. This suggested explanation is supported by the fact that the α-rays of radium are absorbed when they pass through air, and they become less and less penetrating as they pass through increasing thicknesses of aluminium.

Junior Institution of Engineers.—The summer meeting of this institution, which has recently taken place, was exceptionally well attended, a circumstance no doubt due to the particularly attractive character of the programme provided. The proceedings opened at the Town Hall, Sheffield, where the Lord Mayor welcomed the institution. The members then visited the works of Messrs. Davy Bros. at Attercliffe, where they had the opportunity of seeing in course of erection the most powerful armour-plate mill yet constructed. It is for the Imperial Japanese Government, and will be capable of rolling a 40 or 50 ton hard chrome steel ingot into a plate in about 15 minutes. The next visit was to Messrs. Hadfield's Steelfoundry Company's works at Tinsley. A most interesting afternoon was spent in the inspection of the splendid foundry, where steel castings for hydraulic, marine, and other machinery, track work, points and crossings, and mining machinery of all kinds were being turned out. The works of Messrs. Charles Cammell and Co. were also opened to the members, an armour-plate for H.M.S. "Hinduston" being specially rolled on their arrival. The various other processes incidental to armour-plate manufacture were shown. In the foundry marine, locomotive, dynamo, and other castings were in hand. The Toledo Steelworks of Messrs. John Henry Andrew and Co. were visited. Springs, wire, Siemens and Bessemer steel, and specialities in casting steel, rolling mills, mining tools, etc., afforded ample food for a morning's reflection, and in the afternoon the Master Cutler's works (Messrs. Thomas Turner and Co.) were seen. The series of visits was brought to a close by inspecting the works of Messrs. Mellowes, where the well-known "Eclipse" roof glazing is produced, and in the evening the institution summer dinner was held at the Royal Victoria Hotel, the chairman, Mr. Kenneth Gray, presiding. The Master Cutler, the Deputy Lord Mayor, representatives of the different works visited throughout the week, and other guests were present. Same capital speeches were heard in the course of the evening, and an illuminated vote of thanks was presented to Mr. King in recognition of his valuable service as honorary local secretary of the meeting.

Police Telephones.—If the police authorities in this country are still tardy in recognising the full value of the telephone as a means of rapid communication, their *confrères* on the other side of the Atlantic are by no means of the same temperament. In America they have not been slow to accept the great advantages which the telephone has to offer them in their responsible duties of keeping the peace. Thus we find that in practically every city in the States the police have the best telephone facilities at their disposal, but only in some comparatively few cases could the same be said of this country. Now the police authorities in New York are organising a complete independent street telephone system in the borough of Manhattan, which is very soon to be put in operation. An arrangement has been made with a company to carry out the scheme, and the company will maintain the system when completed at fixed rates. The present equipment consists of 660 telephones, which are to be placed in iron boxes, and as far as possible it is intended to place the boxes on the walls of buildings The boxes measure about 15in. by 18in., and will be painted a greyish colour. In each police station a switchboard will be installed, at which will terminate the lines from all the telephones in that particular precinct. The system is to be entirely independent of the existing telephone plant operated by the department, and at first only the police will be put in possession of keys to the various telephone boxes in the streets. The proposition, however, of entrusting keys to drug store proprietors and other responsible parties who could be reached at odd hours is under consideration. The advantages of such a system are obvious. The policemen on duty will be able to quickly get assistance from the stations, and a record of their movements will necessarily be kept, as the men will be required to report at regular intervals during their patrol to their particular station. It is intended later to devise a means of communication from the station house to the men on duty, and ultimately other parts of New York will be similarly equipped. For the information of the police authorities in this country we may say that the annual rental for the 660 telephones to be installed in Manhattan will be £4,171, a really small outlay in comparison with the valuable facilities gained.

New York Subway Cars.—Illustrations are given in the *Street Railway Journal* showing the principal features of the electric cars which are being constructed for service in the new subway in New York. From a view of the interior of one of these cars one concludes that they are very similar in design to those on the Central London Railway, but in construction there are several valuable features noticeable which represent an advance on the older type of car The length over platforms of the new cars is about 50ft., and over car body 42ft. 7in., with a width of between 8ft. and 9ft. The chief point about the construction of the car bodies is the means adopted for protection against fire. For example, the floors are double, with asbestos roll felt sandwiched between, and the floor sheathing is of white pine, completely covered on the underside with $\frac{1}{4}$in. asbestos transite board. Also, all parts of the car framing, flooring, and sheathing are covered with fireproof compound. These precautions to secure safety from fire extend to the arrangement and installation of the electrical apparatus and electrical wiring For the lighting circuits a flexible steel conduit is used, and a special junction box has been designed. On the side and upper roofs over these con-

Digitized by Google

duits for the lighting circuits a strip of sheet iron is securely nailed to the roof boards before the canvas is applied. The entire under portion of the car flooring is covered with electrobestos, and the wires are carried in ducts moulded into suitable forms made from the same material. The pump box under the car is lined with steel. Special precautions have been taken with the installation of the wires, the specifications calling for—first, a layer of paper, next, a layer of rubber, then a layer of cotton saturated with a weatherproof compound, and outside of this a layer of asbestos. The hangers supporting the rheostats under the car body are insulated with wooden blocks, which are subjected to a special process, being dried out in an oven and then soaked in an insulating compound and covered with ¼in. transite board. The rheostat boxes themselves are also insulated from the angle iron supporting them. Where the wires pass through the flooring they are hermetically sealed, to prevent the admission of dust and dirt. In many of these particulars the new cars show a valuable advance on previous practice, and with so many precautions against the dangers of fire the chances of a disaster such as recently occurred in Paris may be regarded as practically nil.

Electric Lighting of Paris.—Now that the public excitement in connection with the recent disaster on the Paris underground railway has more or less subsided, the energetic Parisian has found time to once again turn his attention to a subject which at least is as important as the question of possible reforms in the working and management of the Metropolitan Railway. The lighting of Paris is a problem of which the Municipal Council may well fight shy, for it is beset with difficulties and complications which have more than once been alluded to in this journal. True, the final question will not require to be definitely decided for some two or three years, but the important question as to whether the municipality will take the responsibility for the lighting of the city streets on its own shoulders when the private concessions fall in, is one which calls for early consideration. It is common knowledge that in the French capital the electric light companies, as well as those supplying electric power only, have no monopoly, and almost without exception the concessions expire between 1907 and 1910. There are two courses open to the municipality—either to renew the contracts, or to combine the several undertakings and place them under municipal control. In the city itself there is a strong feeling that the latter course should be adopted, but the Prefect of the Seine, who, to a certain degree, has a right of veto, is said to be examining other proposals. The question assumes greater importance in the light of the fact that during the last few years the electric light has been making steady progress in Paris. The correspondent of the *Financial Times* in that city sends his paper some information with regard to this progress, in the course of which he says that there are six companies in existence, as well as a municipal plant for supplying the central markets, and in 1897 these seven installations furnished current for 11,800 arc lamps and 416,000 incandescent lamps. On Jan. 1 last the number had increased to 17,830 arc lamps and 1,250,700 incandescent lamps, irrespective of those in the railway stations and private factories. Of the 17,830 arc lamps, only 1,910 are used for street-lighting and municipal buildings, together with 6,470 of the 1,250,700 incandescent lamps. There is little doubt that the increase is likely to continue on a progressive scale, but a difficulty in the way lies in the fact that owners of flats have to run to considerable expense when they wish to have the electric light in a house not connected with the mains.

Electrical Progress in Russia.—It is only within the last few years that Russia has shown any great desire to advance in matters electrical, but one notable feature of the progress which has been made is the extensive use of electricity for motive power in factories and works. A consular report from Odessa throws an interesting light on what has been done in this direction and what is going forward at the present time. Thus we find it stated that the use of electricity for the distribution of motive power is spreading, and to-day practically all the machine works of Russia have adopted this method. Enormous central stations have been erected at places where such factories exist, but up to the present electricity has scarcely been used at all for the transmission of energy over great distances. Mention is again made of projects which are under way to utilise the waterfalls of Marva and Imatra for this purpose. In reviewing the position of the electrical industry in Russia some 12 months ago we referred to these schemes, but it does not seem that much progress has been made since. However, the Government has granted a concession to a company to supply power to St. Petersburg from the Volhoy rapids, and the scheme is estimated to involve a cost of nearly three millions sterling. It is proposed to transmit energy over a distance of 188 miles. Another scheme is to use the colossal force of the Dnieper cataracts for the generation and transmission of electrical energy. Electrotechnical appliances will have a great future in Russia, and the home factories are unable to supply the demand. There are many Russian factories, however, which produce cables and insulated conductors at St. Petersburg and Moscow. Chief among these is the Siemens and the Riben establishments, both of which produce cables which compare favourably with the foreign articles. Accumulators are also manufactured in various towns in Russia. There are a number of large establish ments in St. Petersburg which produce accumulators of original design, or after the best known foreign models, such as the Julien, the Tudor, and other types, and the importation is small. Such appliances as circuit breakers, commutators, and rheostats, as well as fittings for lamps, are also manufactured in Russia, but not nearly enough to supply the demand. Measuring and counting instruments are scarcely manufactured at all in Russia, although the demand for them is enormous, especially of late, since central stations have been constructed in a number of towns. These instruments are imported from France and Germany. The manufacture of porcelain insulators and of porcelain appurtenances in general is so largely developed in Russia as to completely satisfy the home demand, and no insulators are imported. Incandescent lamps are not manufactured in Russia at present, owing to the strong foreign competition. Most of the arc lamps also are imported, principally from Germany. One branch of the electrotechnical industry is fully supplied by the home manufacturers, and that is the signalling and telegraphic apparatus in use on the railways, to indicate whether the line is open or closed. As regards telegraphic appliances proper, some are manufactured in Russia and some come from abroad, chiefly from Sweden and Germany. It will thus be seen that the demand for electrotechnical apparatus and machines in Russia is relatively but little satisfied by the home manufacturers, and the progress in the application of electricity for transportation, manufacturing, and domestic economy will undoubtedly enormously increase the market for foreign appliances. The above information will, no doubt, prove of considerable value to manufacturers of electrical apparatus in this country, and should serve as a useful guide to the demands of Russia in their business relation with that country.

NOTES ON THE THEORY AND WORKING OF ROTARY CONVERTERS.

BY W. ROGERS.

In the following short article the writer has attempted to bring together a few notes on the rotary converter, a machine which has done much towards making it possible to combine the advantages of alternating-current transmission and continuous-current working. The rotary converter may be used for converting alternating currents of one, two, or three phases into continuous currents, or *vice versâ*. Its armature has but one set of windings, connected to a commutator at one end, and at the other end tappings from the windings are taken to two, three, or four slip-rings, according to the nature of the alternating current. This one set of windings receives the incoming primary current, at the same time generating the secondary current. Converters in a simple form have been known for some years. One of the earliest types took the form of a two-pole Gramme machine, the armature windings being connected up at one end to an ordinary commutator, and at the other end to two slip-rings, these rings being connected to two points on the winding at opposite ends of a diameter, the machine acting as a single-phase converter. If there had been three slip-rings connected to three symmetrical points on the winding, the machine would have acted as a three-phase converter. Fig. 1 is a table showing the relation between the number of slip-rings, the nature of the alternating current to be put in or taken out of the converter, the angles between the points on the windings which are connected to the slip-rings, and the voltage ratio.

No. of rings.	Angle between connections to slip-rings.	Nature of current.	Voltage ratio.
2	180deg.	Single-phase.	$\frac{1}{\sqrt{2}}$
4	90deg.	Two-phase.	$\frac{1}{\sqrt{2}}$
3	120deg.	Three-phase.	$\frac{1}{2}\frac{\sqrt{3}}{\sqrt{2}}$

FIG. 1.

We will now consider the relation between the currents and voltages on the continuous and alternating current sides respectively. The actual effective voltage of the alternating side of a converter, supplied on the continuous-current side at a constant pressure of 100 volts, equals $\frac{100}{\sqrt{2}} = 70{\cdot}7 = {\cdot}707$ times the continuous-current E.M.F., this being the case with a single-phase converter.

The voltage on the alternating side with a three-phase converter = continuous E.M.F. × ·707 sin 60deg. $= \frac{{\cdot}707 \times \sqrt{3}}{2}$

i.e., single-phase voltage $= \frac{\text{V (cont.)}}{\sqrt{2}}$,

and three-phase voltage $= \frac{\text{V (cont.)}}{\sqrt{2}} \times \frac{\sqrt{3}}{2}$

Nature of current.	Volts.		Amperes		Amperes in line	
	Max.	Eff.	Arm.	Rings.	Max.	Eff.
Continuous	100	100	50	50	100	100
Mono-phase	100	70·7	100	70·7	200	141·4
Two-phase	100	70·7	70·7	50	100	70·7
Three-phase	86·6	61·23	77	54·5	133	94·3

FIG. 2.

Fig. 2 is a table showing the respective values of the maximum and effective voltages, also the relative values of the currents in the armature and line during the conversion of a continuous current into an alternating current of one, two, or three phases. The currents in this table are obtained when the circuit is non-inductive. In the case of an inductive circuit there will be a phase difference in the currents, consequently there will be wattless as well as working currents, and for an equal output of power, the values in columns 4 to 7 in the table must be increased by dividing them by the cosine of the angle of lag. If the continuous current supplied = 100 amperes, the effective value of the alternating current $= \frac{100 \times 100}{70{\cdot}7} = 141{\cdot}4$ amperes, if the current follows a sine curve. If the effective value of the current = 141·4 amperes, its maximum value = $141 \times \sqrt{2} = 200$.

Although, as already stated, it is possible to obtain converters for single, two, or three phase currents, as the two former types are not often met with, it will only be necessary to pass a few remarks on them. In the case of the single-phase converter, it has several disadvantages when compared with the two or three phase type—firstly, it has considerable variations of armature reaction, which is a most important point in the running of converters; secondly, a greater and more unequal heating; thirdly, it is not self-starting from the alternating-current side; and fourthly, it causes a periodic fluctuation in continuous current. In the two-phase converter the heating is more equally distributed through the armature, and there is not so great a tendency to cause fluctuations in the continuous current; also it has a great advantage over the single-phase converter in being self-starting. On account of these distinct advantages it is more often met with in power transmission schemes than the single-phase type, but both types are a long way behind the three-phase type, which we shall now consider at some length, although some of the following remarks apply to all three types of converter.

There are three different E.M.F.'s to be taken into account in a converter: (1) the impressed E.M.F. on the slip-rings; (2) the counter E.M.F. induced in the converter by the armature revolving in the magnetic field, which is proportional to the field excitation; (3) the E.M.F. consumed by impedance, representing the lost volts due to the reactance and resistance of the armature. The impressed E.M.F. depends upon the voltage at the terminals of the generator. The counter E.M.F. depends upon the field excitation, and is constant at all loads. The E.M.F. of impedance is proportional to the current, and varies with the load. Work done by a converter is equal to the product of the current taken by it, and the projection of the counter E.M.F. on this current. At no load this current is at right angles to the counter E.M.F.

The input of a converter equals the product of the impressed E.M.F. and the projection of the current on it, and if we assume no energy is consumed the current is in quadrature with the impressed E.M.F. Now, at any moment we have three separate E.M.F.'s in the system, their sum being always zero; also at any instant we have impressed E.M.F. = counter E.M.F. + E.M.F. of reactance. As the counter E.M.F. is less than the impressed E.M.F. when the converter is under-excited, the E.M.F. of reactance must be in phase with it, and since the current is always 90deg. ahead of the E.M.F. of self-induction, it must be 90deg. behind the impressed E.M.F., and consequently be lagging. Should the field excitation be increased, so that the counter E.M.F. is higher than the impressed E.M.F., the E.M.F. of reactance must be in phase with the impressed voltage. In this case the current becomes a leading current.

As regards the excitation of "converters," they may be either shunt or compound wound. The shunt type is chiefly used for lighting work. It does not admit of phase control, but maintains a constant wattless current at all loads, with constant adjustment of the field. Its power factor is the same for all loads, but changes with various loads when there is any variation in the reactance of the supply circuit. As the pressure on the continuous-current side falls with the load owing to the C R loss, it is necessary to use converters having compound excitation when running on widely varying loads, such as are met with in tramway practice. With this type of converter the pressure on the continuous-current side may be maintained constant, or made to increase with load, as with an over-compounded continuous-current machine. The compound field is so proportioned that at no load it is under-excited. When this is the case the E.M.F. of the converter is less than the impressed E.M.F., and the current in the line is made lagging. This increases the E.M.F. of self-induction, cutting down the voltage of the system. Excitation increases

Digitized by Google

with the load, and the counter E.M.F. is also increased, thus bringing the impressed E.M.F. and current into phase. This is followed by a rise in the voltage at the receiving end and also on the continuous-current side. At full load the counter E.M.F. is greater than the impressed E.M.F., consequently the current leads and the voltage reaches a maximum. From this is derived the fact that a leading current raises while a lagging current lowers the pressure at the terminals of a converter. The power factor of a compound-wound converter, excited for a factor of unity at full load, is not so good when running light. To obtain 10 per cent. over-compounding, the fields must be excited to give a factor of unity at about three-quarter load. The current for compounding in a converter must lag on light

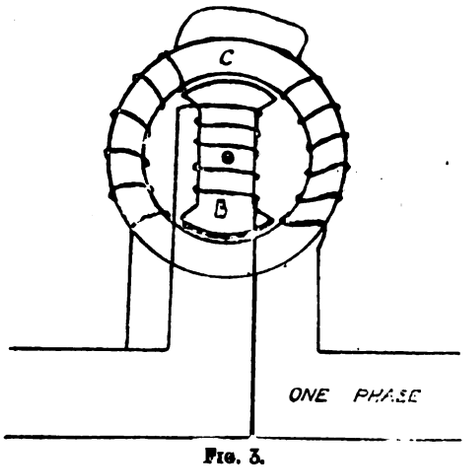

Fig. 3.

loads and lead on heavy loads. This requires a large amount of reactance, and it will, therefore, be seen that self-induction, which is supposed to be the bugbear of alternate-current working, owing to the drop in volts it causes in the system, is absolutely necessary for the satisfactory running of converters, as it raises the pressure with increase of load. A converter may be made to take a leading or lagging current by altering its excitation, and therefore its counter E.M.F. By altering the shunt field and putting choking coils in the alternating supply circuit, the machine may be made to take a lagging current on light load. As the load increases, the compound winding increases the excitation, and this diminishes the lag of the current, thus increasing the pressure on the slip-rings, which is followed by a rise in pressure on the continuous-current side. When full load is reached, the alternating current is leading, and the continuous-current pressure will have increased in proportion to the increased pressure on the slip-rings.

Although the rotary converter possesses similar characteristics to those of the synchronous motor and the continuous-current generator, these facts do not tend to simplify the complications met with in its working. As the pressure between the slip-rings is always a definite percentage of the pressure on the continuous-current side, being about 61 per cent., it is necessary to insert step-down transformers between the slip-rings and the high-pressure bus bars. Whatever the voltage of transmission may be, it is transformed down to about 330 volts by means of three separate transformers having a mesh connection on both high and low tension sides. The advantage of this mesh connection is that in the event of one of the transformers developing a fault and blowing its fuse, the other two will continue to supply three-phase currents to the converter, which will enable it to be kept loaded (although under its full power) until the faulty transformer has been replaced. As the two transformers will be overloaded during the period of emergency, the increase of heating must be carefully watched. Owing to the fact that the ratio of the continuous-current E.M.F. to the alternating impressed E.M.F. is constant, there is a difficulty in regulating the continuous-current side of a converter. As the pressure on either side is independent of the field strength, regulation cannot be effected by varying the excitation. There are several ways of varying the continuous-current E.M.F., but they all work on the same principle—namely, that of altering the pressure applied to the slip-rings. When the load is fairly steady a shunt-wound converter is used, and hand regulation is resorted to, but in the case of a varying load hand regulation is not effective, and must give way to automatic regulation. There are several ways in which hand regulation may be effected: (1) By inserting a choking coil in each phase, which method has the disadvantage of lowering the power factor of the supply. (2) Altering the ratio of transformation of the transformers supplying the converter, by means of a special switch. This method is expensive, inasmuch as it requires a special winding of the transformers.

Another method is that due to the Allgemeine Company, and consists of a small alternator mounted on the converter shaft, its armature windings being connected in series with those of the converter. The small alternator acts as a booster, and may be made to add or subtract volts to or from the supply mains by adjusting and reversing its excitation. This method is also expensive, and is only used when heavy currents are dealt with.

The best method of hand regulation, and that most commonly used, employs a small boosting transformer, known as an induction regulator, in each phase. Fig. 3 shows one form of this apparatus, which consists of a stationary iron core, C, connected in series with one phase. Inside this is placed a moving core, B, carrying a primary winding connected across one phase of the supply mains; this core is capable of being turned through 180deg. The secondary voltage is at its maximum when the core is in a vertical position, and falls gradually as the core is turned round, finally becoming zero when the core is horizontal. When the core is in this position, the fields due to the two windings neutralise one another. If the core is still turned further round, the secondary voltage rises again in the opposite direction, consequently the regulator may be made to add or subtract volts In the case of a three-phase converter, one of these regulators is required in each phase, the handles of each being interlocked, so that the voltage may be equally adjusted in each phase at the same time. On account of difficulties connected with

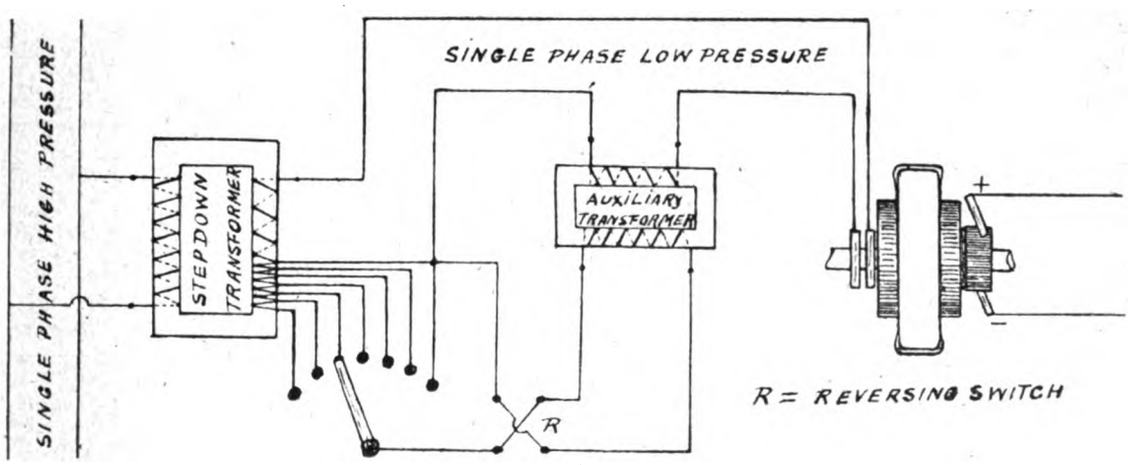

Fig. 4.

Digitized by Google

insulation, inductor regulators are always connected in the secondary circuits of the step-down transformers. Such an apparatus is inexpensive, and is very effective, giving a range of about 5 per cent. both ways, at the same time being unlikely to get out of order, having no contacts. A more efficient form of regulator, due to Mr. M. B. Field, is shown in Fig. 4. The secondary of each transformer carries a few extra turns, which are connected through a small regulating switch to the windings of a small auxiliary transformer whose secondary winding is in series with the low-tension circuit, adding or subtracting a small voltage to this circuit as desired. We shall now consider a method of automatic regulation which is used in connection with the compound-wound converter. It consists of introducing a certain amount of self-induction between the secondaries of the step-down transformers and the slip-rings by means of choking coils. The action depends on the fact that the excitation controls the phase relation existing between the alternating current flowing into the converter and the voltage at its terminals. We have already seen that the excitation necessary for a power factor of unity varies with the load, the current being in phase with the voltage. Should the excitation be too small to give a power factor of unity at any particular load, the supply current lags behind the voltage; if the excitation is too great the current leads the volts, and the power factor is again less than unity. The effect of this is to cause the voltage across any self-induction in the circuit to vary in phase with the voltage of the supply, which in turn varies the voltage supplied to the slip-rings.

Comparing the methods explained above for regulating the pressure on the continuous-current side, it will be seen that in the case of the shunt-wound converter running on a lighting circuit very good regulation can be obtained by employing induction regulators worked by hand in accordance with the varying load. For traction work the employment of the compound converter in which regulation is effected by means of lagging and leading currents, is to be preferred on account of the wide variations of the load. As the running of converters presents some difficulty, owing to the special character of the machines and regulating devices, it might be well to say a few words on their starting. A converter may be started up by applying an alternating current to the slip-rings or a continuous current to the commutator. When it is started up on the alternating side, it must first be run up to speed in the same way as a synchronous motor-generator. In some cases a small induction motor is coupled to the converter shaft, the high pressure being simply switched on to it when starting up. They are also sometimes started up by synchronous motors. A converter may be started on the continuous-current side in the same way as a shunt motor. The fields should be fully excited, and a resistance placed in the armature circuit at starting. When the machine is running at full speed it is synchronised with the alternating supply; then the field switch supplying the excitation for starting is opened, and the switch supplying its own field closed. In starting up from the alternating side there is some difficulty in finding out the polarity on the continuous-current side. This is because the converter depends for its excitation upon the polarity that its commutator has at the moment it is synchronised. If the station plant includes two or more converters, and the first machine comes up with a wrong polarity, it may be allowed to run until the second one is synchronised. The second machine can then be given any desired polarity by using the first machine as a source of continuous current. Then from the second one the polarity of the first machine may be reversed, the second machine being then shut down. When the machines have heavy armatures, it is best to control the polarity of the first machine when it is started from the alternating side. As the machine approaches synchronism, the needle of the continuous-current voltmeter will vibrate rapidly about the zero mark with a short swing. These will be followed by a few slow long swings in opposite directions from the zero mark. Near the maximum point of whichever of these swings is in the direction of the desired polarity, the field switch should be closed, when the machine should excite itself, if the terminals have the correct polarity. If the field is put on when the needle is on the wrong side of the scale, the polarity of the converter is reversed, which means that it must be synchronised again. To ensure the machine being synchronised at the right pole it is well to have an indicator on each continuous-current panel, so that the polarity may be checked before the machine is connected to the continuous-current 'bus bars. These remarks only apply to a self-exciting converter. If the machine is excited off the 'bus bars, which is seldom the case, it will pull itself round to the correct polarity if it has been synchronised at the wrong pole. When a converter is driven from the continuous-current side it runs as a shunt motor, consequently its speed depends on the field strength and also upon armature reaction. When a lagging current flows from the alternating side the armature reaction reduces the field strength, consequently the speed rises. As this armature reaction is always considerable when the converter delivers an alternating current, the armature is liable to wide variations of speed as the load varies, and may easily reach an excessive speed unless special means are taken to prevent it. With the Westinghouse type of converter for delivering an alternating current is provided a small exciter having an unsaturated field, so that any slight increase in its speed causes a marked increase in the voltage it generates. Should the speed of the converter increase, its field is greatly strengthened, thus preventing any further rise in the speed. When a converter is supplied with power on the alternating side, it runs as a synchronous motor, keeping step with the main alternators. Any change in speed of the latter will similarly affect the converter. Sometimes these variations in the supply circuit are so rapid that the converter cannot follow them, and the result is a pulsation in speed known as "hunting" is set up. This has the effect of causing a fluctuation in the pressure on both sides of the converter, making it impossible to obtain constant pressure on the continuous-current side, at the same time causing sparking and flashing over on the commutator, besides throwing the converter out of synchronism if steps are not taken to check the "hunting." There are several conditions of working which tend to cause "hunting," and they may be briefly enumerated as follows: (1) a difference in the E.M.F. waves of the generators and converters; (2) employing machines having a strong armature reaction and working with under-excited fields, or machines having a high momentum; (3) employing engines having an unequal turning moment. In checking this tendency to "hunt," some means must be devised for damping the oscillations or speed variations set up in the armatures through the above-mentioned causes. This may be brought about by (1) working with over-excited fields; (2) lessening the amount of distortion of the fields by means of damping coils. As used in Westinghouse converters, the damping coils consist of copper strips bridging the poles from horn to horn. Eddy currents are induced in these strips (by the action of the leading and lagging armature currents), and these have the effect of preventing the distortion of the main field. At the same time they tend to steady the speed of the generating machines.

A very important question in connection with converters is that of parallel running. Although their tendency to "hunt" has something to do with this question, there are other points which must be considered. Although parallel running of these machines is possible, it will be readily understood that the best results are obtained when they are running on independent circuits. Converters may be run in parallel on the continuous or alternating current sides, but when they are required to be operated in parallel on both sides they must be provided with a separate group of step-down transformers for each machine, the low-tension leads being kept quite separate. This is to prevent what are known as parasitical currents being exchanged between the two machines, as a result of a difference in the wave-forms of their counter E.M.F.'s, and which would be the cause of one machine giving a larger current from its positive brush than that going in at its negative brush, and *vice versâ* in the case of the other machine. In practice the necessity for using another group of three transformers is done away with by winding each unit forming the group of three step-down transformers

Digitized by Google

with an additional secondary winding. The connections are similar to those on the alternating side of the diagram shown in Fig. 5, which represents the arrangement of connections for the parallel running of two converters on the alternating side, the continuous-current sides supplying current to a three-wire network. Under these circumstances it is impossible to run a number of converters in parallel on the alternating side, because the slip-rings cannot be paralleled, as the connection already exists on the continuous-current sides. We shall now consider the question of the frequency at which it is

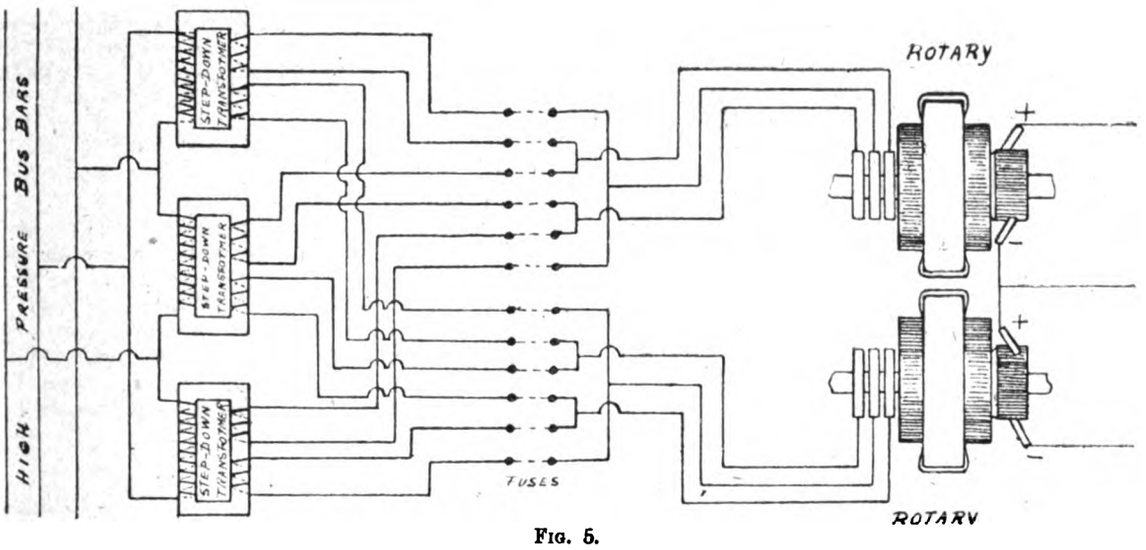

FIG. 5.

desirable to run converters. The limit of successful operation is about 40 cycles. With a higher frequency good parallel running becomes impossible, as the machines have a great tendency towards "hunting." Parallel running is always more satisfactory when the machines are operated at a low frequency, because the phase difference between the E.M.F. waves of the machines is not so large, also a high frequency requires a large number of poles on the converter. For the reasons mentioned above a frequency of 25 cycles has been fixed as a standard for converters, but they are generally operated at about 30 to 35 cycles when the whole output of the station is not absorbed by converters, as such a low frequency as 25 cycles is undesirable for the working of motors and transformers, lighting work being quite out of the question. There are a few special points in converters which should not be overlooked. As the motor and generator currents overlap in

and V a voltmeter on the continuous-current side. Another ammeter not shown in the figure must be put in the field circuit, so that the exciting watts may be found. A^1 is an ammeter and V^1 a voltmeter on the alternating side. R is an adjustable resistance, and Q a three-phase rheostat used as a load. W^1 and W^2 are wattmeters, and S a three-pole switch. Readings of the instruments are taken for several different values of speed and load, the efficiency being calculated in the following manner:

Total watts put in $= A\,V + C^2\,r$, where $C^2\,r$ = exciting watts.

Total watts given out $= W^1 + W^2$.

$\therefore$ Watts lost in converter $= (A\,V + C^2\,r) - (W^1 + W^2)$.

$\therefore$ Efficiency of converter $= \dfrac{W^1 + W^2}{A\,V + C^2\,r} \times 100$.

The ratio of conversion $= \dfrac{V^1}{V} \times 100$.

In this test the machine is run as an inverted rotary—*i.e.*, it is converting from continuous to alternating current. From the results of the test an efficiency curve may be plotted having values of $(W^1 + W^2)$ as abscissæ and the corresponding values of efficiencies as ordinates.

In conclusion, it might be well to consider the advantages and disadvantages of the rotary converter as a transformer for alternating and continuous currents. Among its advantages may be mentioned: (1) a large overload capacity; (2) high

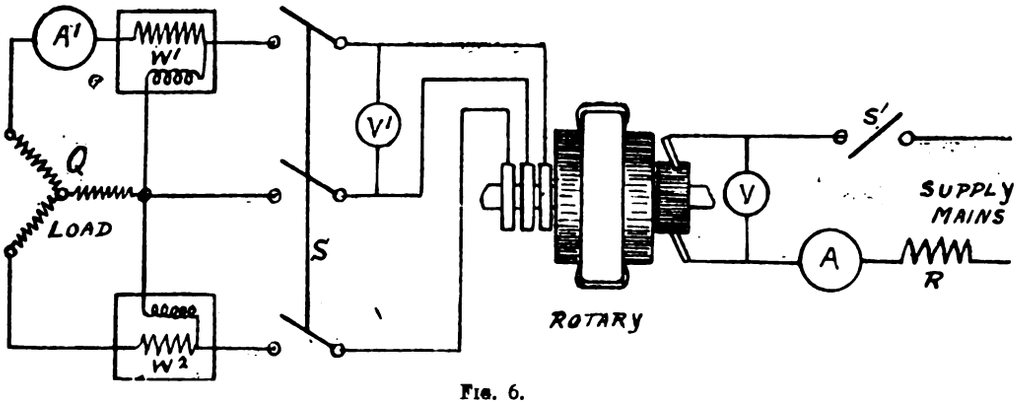

FIG. 6.

the armature conductors, the latter may be of small section for a given output. In consequence of the armature reaction being neutralised, it is possible to use a large number of conductors on the armature; for the same reason it is unnecessary to shift the brushes during variations of load. The efficiency of a converter is practically the same as that of a continuous-current machine of similar type and capacity, and depends to some extent on the frequency of the supply alternating current. In large machines it varies from about 90 per cent. half load to about 94 per cent. full load. An example of an efficiency test of a converter might be of interest, Fig. 6 being a diagram of the connections necessary for such a test. A is an ammeter

efficiency; (3) relatively low cost and high power factor. In comparing the cost of rotary converters with other forms of transforming machinery, it must not be forgotten that step-down transformers must be provided, which increase the cost and lower the efficiency of transformation. The disadvantages of the converter are: (1) sensitiveness in parallel running; (2) necessity of using complicated regulating apparatus and switchgear; (3) requires skilled attendance; (4) to obtain satisfactory working it must be operated by currents of low frequency, which are undesirable for use in other forms of transforming apparatus, so far as economy in copper is concerned. Notwithstanding these disadvantages, the rotary converter will continue to

play a very important part in the working of the large power schemes which are springing up all over the country in connection with electric traction and the supply of electrical energy in bulk.

SOME NOTES ON THE DESIGN OF MAGNET SYSTEMS FOR CONTINUOUS-CURRENT MACHINES.

BY T. SQUARE.

Before we can begin designing the magnet system for a continuous-current dynamo or motor we must first decide upon the number of poles which we propose to use, the effective polar embrace, and the maximum flux which will be required per pole. These questions are almost entirely dependent on the design of the armature, so we will only dwell shortly upon them here. The best *number of poles* is determined mostly from three considerations:

1. *Good Commutation.*—In order to satisfy this, or, rather, to get the best result possible, the number of turns per armature coil should be kept as low as possible, preferably one. This means where the number of turns per coil exceeds this figure the number of poles should be reduced. Of course, if the commutation constants are already sufficiently good, we need not give so much weight to this consideration.

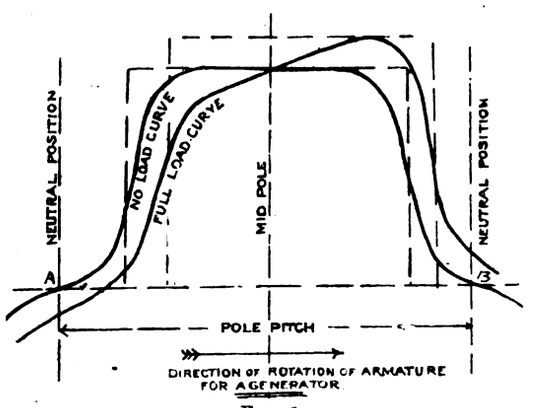

FIG. 1

2. *Cost.*—The cost price of a machine may be roughly divided into two parts—cost of materials and wages. In large machines the former is by far the greater proportion of the total; in small machines the reverse is the case. Now, a large number of poles increases the work required to construct the machine and hence the wages, and decreases the cost of materials. A small number of poles works in exactly the opposite way, hence we should use a large number of poles on a large machine and *vice versâ*. The best number from this point of view can only be found by working out a number of cases and seeing how the cost varies.

3. *Weight.*—For some purposes weight is of great importance. To get a light weight we must obviously go for a large number of poles, thus reducing the weight of both armature and magnet system.

In order to determine the *effective polar embrace*, we must plot the flux densities in the air-gap at various points along the pole-pitch when running at no load and full load, and we shall probably get curves something like those shown in Fig. 1. These curves can be obtained experimentally from similar machines already made, by measuring the volts between each two adjacent commutator bars all along a pole-pitch by means of two exploring brushes fixed just one commutator bar pitch apart. This voltage can best be read by balancing it against a potentiometer; in this case no current flows through the exploring brushes, so there is no voltage drop due to chattering and sparking, and very steady readings can be obtained. These voltages should be expressed as flux densities and the results plotted. The distortion of the full-load flux distribution curve is, of course, due to the armature reaction. In order now to find the effective polar embrace, find the area of these curves and divide by the maximum height. The ratio of the dividend to the pole-pitch (A B) gives us the effective polar embrace required. In other words, it is the amount which the line A B has to be squeezed up to give a perfectly square wave, with a height equal to the maximum height of the wave, and area equal to its area, as shown dotted in Fig. 1. The effective polar embrace does not vary very much between no load and full load, and for all loads with average machines it lies between ·65 and ·75, according to the design of the pole tips and shoes. This value may also be calculated from the drawings of the machine, but the operation is rather long and will not be gone through here. In alternators with a sine wave of flux the calculation is easy. We have, as in Fig. 2,

$$\text{Area of sine wave} = 2\int_0^{\frac{\pi}{2}} y\,dx = 2\int_0^{\frac{\pi}{2}} \sin x\,dx$$

$$= -2\left(\cos\frac{\pi}{2} - \cos 0\right) = -2(0-1)$$

$$= 2$$

and maximum height = 1. ∴ Effective polar embrace $= \frac{2}{\pi} = ·636$.

If we work out the net area of the teeth under each pole and multiply it by the effective polar embrace, we shall get the effective tooth area. If we take any flux per pole and divide it by this area, we shall get the maximum density the teeth reach. This determines the iron loss of the armature, and also the excitation ampere-turns required to drive this flux through, since they also are determined by the maximum density reached.

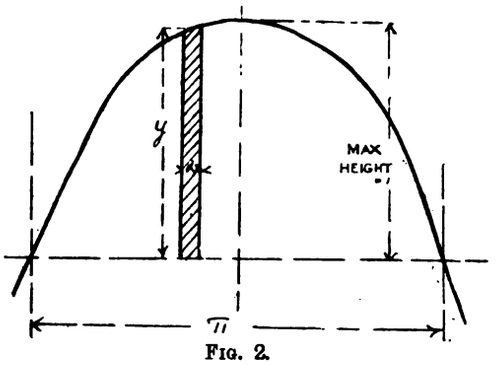

FIG. 2.

The normal working flux per pole is determined from a great many considerations, but with average modern designs the densities in the teeth come out very closely to those given in the table below. These figures, therefore, form a very good basis for design. Having determined the flux per pole from the product "effective tooth area" times "density in teeth per unit area," we proceed to calculate the sections of poles and yoke required in order to give densities there also in agreement with the table below.

I.—TABLE OF FLUX DENSITIES IN MAGNET SYSTEMS IN LINES PER SQUARE CENTIMETRE.

Diameter of armature Inches.	Maximum tooth density per sq. cm.	Pole density.	Yoke density. Cast steel.	Yoke density. Cast iron.
4 to 8	16,000	13,000	13,000	6,000
8 to 16	16,000 to 19,000	13,000 to 14,000	13,000 to 14,000	6,500
16 to 24	19,000 to 21,000	14,000 to 14,500	14,000 to 14,500	7,000
24 to 40	21,000 to 22,000	14,500 to 15,000	14,500	7,500
40 and above	22,000 to 23,000	15,000	14,500	7,500

The tooth density given above is the "apparent"; the "real" density is slightly less, owing to some of the flux passing through the slots, instead of it all, as we have assumed, passing through the teeth. This correction is, however, not of very great importance in determining the normal working flux per pole, so we will neglect it here.

Before we finally work out the sections of pole and yoke required, we must remember that all the flux generated by the field coils does not cut the armature conductors. This is due to leakage, principally between the pole-tips, the pole-flanks, and a little, perhaps, through the air-gap and along the tops of the teeth. For ease of calculation, however, it is assumed that all the leakage takes place between the pole-tips, which is approximately true. Under this assumption, the flux traversing the poles and yoke is the same at all points of the path. The ratio

Digitized by Google

$$\frac{\text{Total flux in pole}}{\text{Total flux cutting armature conductors}}$$

is known as the *leakage coefficient* of the machine.

The normal working flux per pole which we have found above is the flux cutting the armature conductors, so that we must multiply this value by the leakage coefficient before dividing it by the permissible flux density in order to determine the required section of poles and yoke.

We can easily find the leakage coefficient of a machine by a simple experiment on one which is similar in design. Two search coils, x and y, are wound as in Fig. 3, one

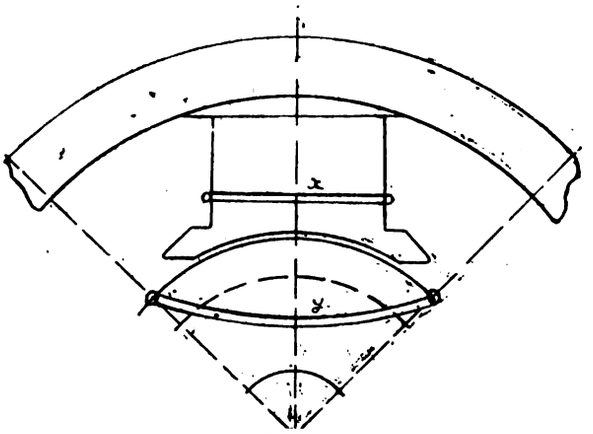

FIG. 3.

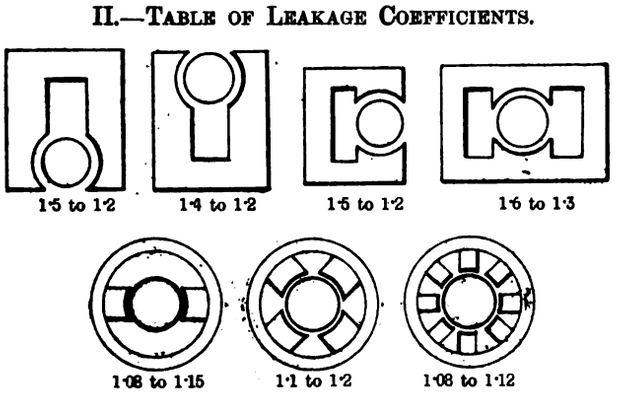
about one-third the way up the pole, where the maximum number of lines is linked, and the other on the armature, just spanning a pole-pitch. These two search coils are each connected to a ballistic galvanometer. The field current of the machine is then reversed, and the ballistics are deflected by an amount proportional to the number of lines linking the two search coils. The ratio of these two deflections will evidently give us the leakage coefficient required. The two ballistic galvanometers must have very long time constants—*i.e.*, be heavily weighted—as the complete reversal of flux in a large magnet system may take some seconds. The following table gives the average results found from practice for the leakage coefficients of several common types of magnet systems.

II.—TABLE OF LEAKAGE COEFFICIENTS.



Type of Magnet System and Leakage Coefficients.

E. Arnold has given the following formula for calculating the leakage coefficients knowing the dimensions of the magnet system, and the writer has found them to give results which are in close agreement with those found subsequently on the same machines by experiment, as shown above.

We have $H = \frac{4\pi}{10\,l} \times$ total ampere-turns.

Since practically all the leakage paths are in air, H = density of flux $= \frac{\text{flux}}{\text{area}}$.

Let M = total ampere-turns per pole. Then

$$M = \frac{\text{flux}}{\text{area}} \times \frac{10}{4\pi} \times l. \quad \therefore \frac{\text{flux}}{4\pi\,M} = \frac{\text{area}}{\text{length}} \text{ for any path.}$$

If we neglect the magnetic resistance of the poles and yoke in comparison to that of the air-gap and armature teeth, we have that the ampere-turns acting across the pole-tips are = 2 M.

We can now split up the leakage flux as follows:

1. *Leakage Between Poles in a Circumferential Direction.*—(*a*) Between the pole-tips: If we look at Fig. 4, noting the symbols given to the various dimensions, we shall see that the length of this path is a_0, and that its area, since there are two tips to each pole, will be $2\,L\,h$

$$\therefore \frac{\text{flux}}{\cdot 4\pi \times 2\,M} = \frac{2\,L\,h}{a_0}, \quad \text{or} \quad \frac{\text{flux}}{\cdot 4\pi\,M} = \frac{4\,L\,h}{a_0}.$$

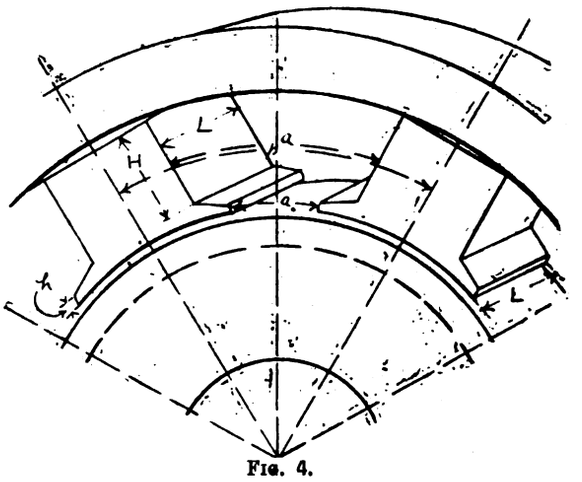


FIG. 4.

(*b*) Between the two flanks in a circumferential direction: In the same way

$$\frac{\text{flux}}{\cdot 4\pi\,M} = \frac{2\,L\,H}{a}.$$

The length of mean path a should be taken half-way up the pole, and the ampere-turns acting across the flanks vary from zero at the yoke to 2 M at the pole-tips. The mean value, M, is, therefore, taken in the above formula.

2. *Leakage Between the Ends of the Poles, as in Fig.* 5.—(*a*) Between the pole-tips: Take any strip dy. Its area is equal to $dy \times h$. The length, assuming the path to be composed of two quadrants of a circle with centre at corner of the pole, as in Fig. 5, and the straight line joining them, will be

$$= a_0 \times \pi\,y.$$

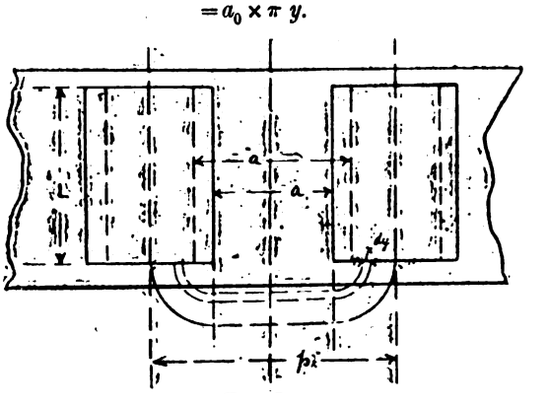

FIG. 5.

Now, the ampere-turns acting are 2 M, and there are four branches to this leakage path, one from each corner of the pole-face. Hence we have

$$\frac{\text{flux}}{\cdot 4\pi\,2\,M} = 4 \times \frac{\text{area}}{\text{length}}$$

or,

$$\frac{\text{flux}}{\cdot 4\pi\,M} = 8\,h \int_{y=0.}^{y=\frac{p-a_0}{2}} \frac{dy}{a_0 + \pi\,y}$$

$$= \frac{8\,h}{\pi} \log_e \left\{ 1 + \frac{\pi}{2} \frac{p - a_0}{a_0} \right\}.$$

(*b*) Between the pole ends: Here, again, we have four branches, but the ampere-turns acting vary from 0 to 2 M, the mean value being, therefore, M. We have, therefore,

Digitized by Google

$$\frac{\text{flux}}{\cdot 4\pi M} = \frac{4H}{\pi}\log_e\left\{1+\frac{\pi}{2}\frac{p-a}{a}\right\}.$$

Hence $\dfrac{\text{total leakage flux}}{\cdot 4\pi M}$

$$= \frac{4Lh}{a_0} + \frac{2LH}{a} + \frac{\cdot 8h}{\pi}\log_e\left\{1+\frac{\pi}{2}\frac{p-a_0}{a_0}\right\} + \frac{4H}{\pi}\log_e\left\{1+\frac{\pi}{2}\frac{p-a}{a}\right\}$$

or, $\dfrac{\text{total leakage flux}}{\cdot 4\pi M} = \dfrac{4Lh}{a_0} + \dfrac{2LH}{a}$

$$+6h\log\left\{1+\frac{\pi}{2}\frac{p-a_0}{a_0}\right\} + 3H\log\left\{1+\frac{\pi}{2}\frac{p-a}{a}\right\}$$

From this we find the total leakage flux, and

$$\text{Leakage coefficient} = \frac{\text{armature flux + leakage flux.}}{\text{armature flux.}}$$

We can now, therefore, determine exactly the section of pole and yoke we require. We will consider now a few points in connection with the

MECHANICAL DESIGN OF THE MAGNET SYSTEM.

First consider the *poles* themselves. These are always made of wrought iron or mild steel (very often of the same quality as the armature core plates) in order to keep the length of the mean turn of the field winding as small as possible. Wrought iron, mild steel, or cast steel being, roughly, of twice the permeability of cast iron, we can for a given ampere-turns run at twice the density, and so have $\frac{1}{\sqrt{2}} = \frac{1}{1\cdot 414} = \cdot 707$ of the length of mean turn with round poles. Poles can be either solid or laminated. If the latter, the poles are rectangular in section, and pole and pole "shoe"

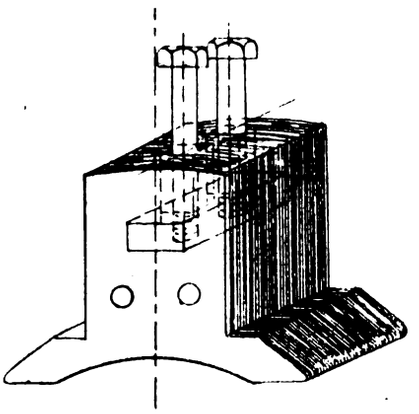

FIG. 6

are all punched out of one plate. The object of lamination is to reduce the hysteresis and eddy-current losses in the pole-face. As each tooth passes in front of a pole it carries a bunch of lines or wave of flux with it across the pole-face. This sets up a variation of flux density in the pole-shoe, which, although its amplitude is small, has a very high periodicity, and hence the resulting loss may amount to something appreciable unless reduced by lamination, as in the armature core. The effect probably does not extend very far into the pole, but as it makes a simple construction many makers laminate the whole pole. In order to secure these poles to the yoke, it used to be thought necessary to tap the thread into which the bolts were to be screwed in a key on to which the plates were threaded, as shown in Fig. 6. It is, however, quite strong enough if the holes are drilled and tapped straight into the laminations.

The best construction is, however, the writer considers, to have a solid round pole cast into the yoke, or cast with it, and having a laminated pole-shoe screwed to its face with counter-sunk screws (Fig. 7). By this arrangement we get even a smaller length of mean turn, being the perimeter of a circle against that of a square at best, thus reducing the weight of field copper required in the same ratio. We also avoid fastening the whole pole to the yoke by bolts, and have only to screw on the comparatively light pole-shoes. Again, only so much of the pole is laminated as is affected by the variation of flux density. The round bar iron which is used for the poles can always be obtained up to fairly large diameters, and needs no further machining except to be bored out when cast in place. This "casting-in" process has been universally adopted by the English Electric Company, of Preston, and many other large firms. The

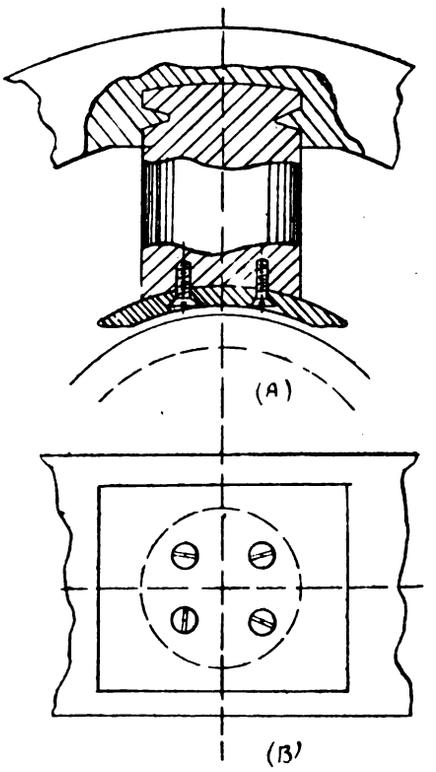

FIG. 7.

poles when ready are built into the mould, and the yoke is run in around them. Of course, this construction only applies to cast-iron yokes. If the yokes are of cast steel, the poles should be cast with them.

(To be continued.)

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

617. In an alternating-current system generating at 2,000 volts, with the outer earthed at the works, where the area of supply is a scattered one and house transformers are used connected to the high-pressure mains, what is the best way of testing the insulation of these mains without disconnecting the transformers, so as to keep ahead and get warning of any faults which may be developing?—C. M. R.

618. A 1-h.p. continuous-current motor, running at 1,200 revolutions per minute, drives a machine by means of gearing at the rate of 100 revolutions per minute. This machine requires to have its direction of rotation reversed every two minutes. Describe some automatic arrangement controlling the motor by means of which these reversals can be obtained.—W. F. S.

ANSWERS.

Question No. 609.—Can anyone tell me which is the best contact breaker to use on a medical induction coil, giving their reasons for thinking so

Digitized by Google

Best Answer to No. 609 (*awarded* 10*s.*).—The question asked by "J. S." is extremely vague. Of the induction coils now made, 60 per cent. are for medical purposes of one kind or another. The factors determining the choice of contact breaker are: (1) The specific purpose in view. (This may be either (*a*) application of weak currents for nerve stimulation; (*b*) production of high-frequency oscillations; (*c*) X-ray work. (2) The voltage of supply.

Where batteries are employed, and a small medical coil for nerve stimulation is used, nothing can beat the ordinary hammer make and break, though certain points should be looked to in designing one. The hammer should be near the end of the core, the spring should be short and moderately stiff; it should have a piece checked out near the support; the platinum should be near the centre of gravity of hammer. The platinum contacts should be not less than 16 S.W.G., the one on the hammer being larger than that on contact screw. The contact screw should be of fine pitch with a locking screw—without this the contact breaker will be most erratic (see Fig. 1). A contact breaker

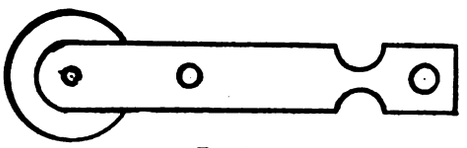

Fig. 1.

of this kind with pure platinum contacts (not silver or nickel as *very commonly sold*) will require adjustment, but seldom provided condenser is suitable. For very rapid

Fig. 2

break Fig. 2 does well. It requires practically no adjustment, but is rather sore on the battery. A is a stiff steel strip, B is a lighter strip, both with platinum contacts. Both are in tension. This combination vibrates at a very high speed, and with small coils is not so painful or jerky as the ordinary contact breaker.

(*b*) For the production of high-frequency currents, the contact breaker should have high speed and yet permit heavy currents to be used. The most satisfactory type for this is the mercury dipper. After years of experience I have found no other that can be used so long at a time with consistent results. If the design of this it should be noted that armature of motor should be light; all moving parts should be as light as possible; contact to dipper should be positive, and not through oily crank or slipper; a powerful spring should aid in lifting dipper; there should be plenty of mercury covered with 2in. to 3in. methylated spirit. Fig. 3 shows one such found most reliable by the writer.

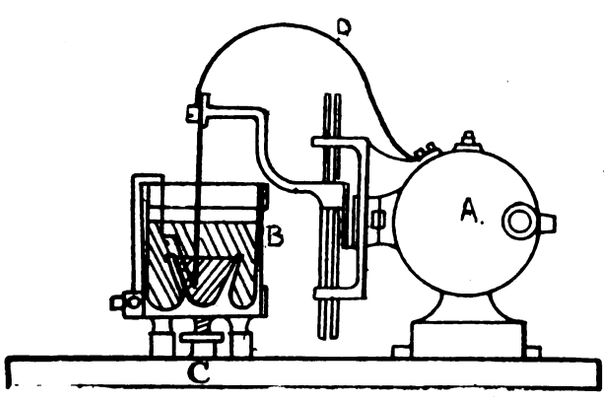

Fig. 3.—Part in Section. A, Motor; B, Glass Vessel with Mercury and Methylated Spirit; C, Reg. Screw; D, Flat Spring.

Many types, such as the McKenzie-Davidson interrupter, use a segment or segments, as in Fig. 4. All these, however, churn up the mercury, cannot be used long at a time, and require very frequent cleaning, besides being wasteful in mercury.

(*c*) For X-ray work there are two cases to consider—screen work and photography. For screen work the high-speed segment dipper, such as the McKenzie-Davidson, is very suitable, as the screen is seldom required for lengthy periods and the illumination with the segment dipper is perfect. For photography, where penetration is most required, the slow but simple dipper is far and away the best. Fig. 3 with the motor slowed down is very suitable. For instantaneous work, however, nothing can equal the Wehnelt electrolytic break. Many of those on the market are very erratic and unreliable. The requirements are: (1) correct strength of acid; (2) plenty of acid; (3) parts of massive size and non-corroding. The Wehnelt, however, is apt to smash tubes, and cannot be used more than a few seconds at a time. The writer has got over the difficulty by connecting an ordinary dipper break in series with the Wehnelt. The dipper then acts as a switch to the

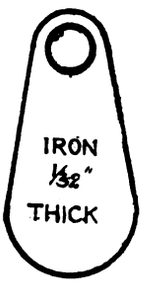

Fig. 4.

Wehnelt, and the tube is at least as long off as on, and therefore has time to cool. This arrangement has given excellent results, especially in cases where the supply voltage is 200 to 250. It is then economical, safe, and reliable. A special condenser on the dipper circuit is, however, advisable.

In a busy practice with coils working four or five hours per day the great difficulty is to keep the contact breakers cool. All kinds of breakers have been designed to get over this trouble, but with little success. The writer has designed and is experimenting with a break for continuous use. The first model consists of a glass tube about ¼in. bore, with a bunch of platinum wires inserted at each side. To the branch shown is a small pump filled with mercury, while the end is connected to the high-pressure water-main. A jerk of the pump sends in some mercury, which is shot through with great violence, making and breaking contact. A grand spark is given, while no spark to speak of is seen at the break in the tube. Any one is at liberty to make and use this. Contact breakers using jets of mercury are very unsatisfactory, as they churn up the mercury into minute globules, which do not conduct, and later get choked up with oxide and carbonised oil.

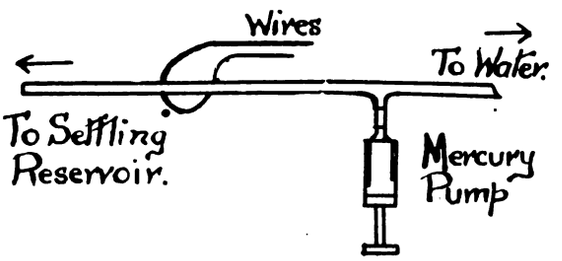

Fig. 5.

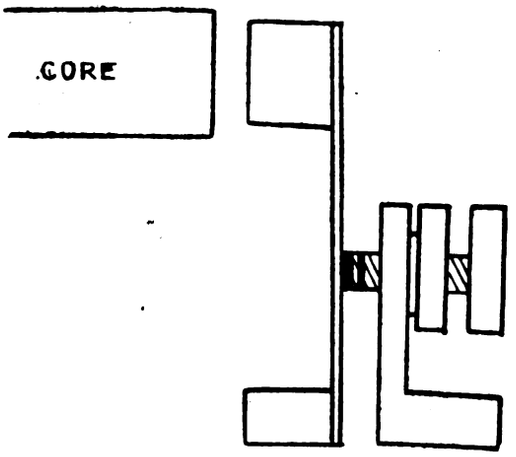
Finally, a word on contact-breaker motors. Most of them are simply toys. They should have well-insulated windings, not less than eight-section built-up commutators, carbon brushes not less than ⅜in. square, or round composite brushes ⅜in. diameter. Bearings should be phosphor bronze and renewable, with means for oiling; parts requiring adjusting should be accessible, and lastly, but very important to be noted, the motor, if driven off the same circuit as the coil uses, should be thoroughly insulated from the dipping circuit.—POLYPHASE.

Answer to No. 609 (*awarded* 5*s.*).—Premising that the induction coil is to be employed for physiological effects, such as the application of "shocks" to various parts of the body, there would appear little doubt but that the ordinary make and break at platinum contacts is the most suitable, all things being considered. The two methods in general use are making and breaking at platinum contact pieces,

Digitized by Google

or dipping a platinum wire in and out of mercury. When a comparatively large current flows in the primary circuit, as in coils used for radiography, where the current may be several amperes, some form of mercury make and break is desirable. With such a current, platinum contacts are very liable to fuse together and give trouble. In a medical coil, however, the current to be dealt with would be but a fraction of an ampere, and with well-made platinum contacts and ordinary care there should be little difficulty in keeping the contact breaker in a satisfactory condition. Objections to the mercury form are that it is larger, and is not so conveniently portable as the ordinary spring and screw with platinum contacts. Although the mercury may be rendered more viscous if some silver is dissolved in it, to obtain the best results it is necessary to have a layer of alcohol on the surface of the mercury. Unless the mercury is covered with alcohol, the sparking soon sets up oxidation. In favour of the mercury form, it is claimed that the presence of the alcohol causes the interruption to be more sudden, owing to the arc being extinguished so quickly, and that by having an adjustable weight on the rocking lever carrying the platinum wire, the rapidity of making and breaking the circuit is under control of the operator. These advantages, however, may easily be obtained with the other arrangement, as by placing the platinum rather low down the spring, as shown



in figure, so that the spring takes a bend before actually breaking contact with the screw, break is very quick, and by adjustment of screw considerable variation may be obtained in the rapidity of the interruptions. If the form of spring is horizontal instead of vertical, as shown, the same result would follow by having contact nearer fixed end of spring. It would appear, therefore, that for a medical coil the ordinary spring with platinum contacts is better for the purpose than a mercury arrangement, on the grounds of being more compact, more portable, and at least as efficient.—M. M.

Answer to No. 609 (*awarded* 5*s.*).—One of the most simplest yet rapid type of contact breaker for large induction coils is the Wehnelt interrupter, which is based on electrolytic action. In Fig. 1, *h* is a vessel containing a

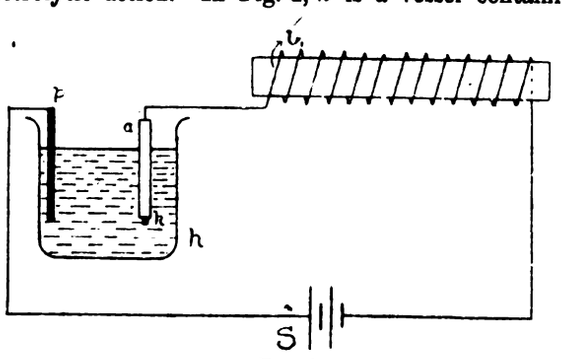


Fig. 1.

dilute solution of sulphuric acid, generally about one part of strong acid to ten of distilled water; *p* and *a* are two electrodes, which convey the current from the battery, S, through the electrolyte. The electrode, *a*, is a glass or porcelain tube through which runs a wire which is provided with a platinum point, *k*. The current from S flows through the primary coil, *b*, to the electrode *a*, and through the electrolyte, from *k*, to the electrode *p* (which is merely a lead plate), and back to S. In this illustration *k* forms the anode and *p* the cathode. The current in flowing through causes an evaporation of the electrolyte to take place at *k*, by reason of the heat generated (Joule's law), thus causing an accumulation of steam and gas around the point, *k*. The steam and gas being bad conductors break the circuit; at the same instant the interruption spark explodes the small quantity of mixed steam and gas, and it flows upwards along the tube, *a*. The electrolyte then further surrounds the point, *k*, and the action is repeated. The heat necessary for the production of the steam and gas bubble arises partly by the heating of the particles conveying the current, but is especially due to the Peltier effect, which in electrolytic action on the anode causes an active development of heat to take place in certain circumstances, a cooling effect taking place at the cathode. For this reason the tube, *a*, with its platinum point, *k*, must always be the anode in the Wehnelt interrupter. This type of interrupter is also made with two, three, or four anodes, held in a common arm, and these can be connected up together, or singly, and thus obtaining a different frequency varying from 260 to 2,000 makes and breaks per second, which has a considerable advantage over the ordinary hammer contact breaker.

Another consideration, owing to the high price of

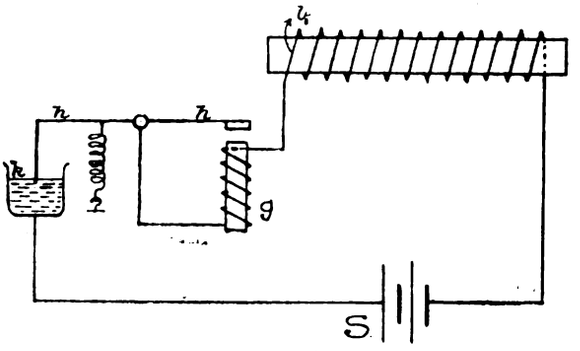

Fig. 2.

platinum, is the rate at which it wears away, due to the sparking when the current is broken in the primary coil. This wearing is very much diminished in the case of a Wehnelt interrupter compared with that of the hammer type. On the other hand, the Wehnelt interrupter must not be overloaded or used too long without a rest, or the platinum points will become overheated and may melt.

A modification of the hammer contact breaker is shown in Fig. 2, and is called the mercury interrupter, but is only suitable for smaller induction coils (not more than 5in. spark). In this case the alternate switching in and out of the primary current circuit is effected by the dip of a metal point in mercury. With this device the current flows from the battery, S, to the primary coil, b_1, the electromagnet, *g*, the dip, *h*, the mercury contact, *k*, and back to S. The armature of the dip, *h*, is attracted, the metal point (generally of platinum) is raised out of the mercury, and thus the circuit is broken. When this occurs the magnet, *g*, releases the armature, and the point, *k*, drops either by its own weight or generally by the action of a spring attached to *h*, and thus the circuit is made again by the point, *k*, dipping in the mercury, thereby causing a fresh impulse to be effected. This device is not found much more suitable in current practice than the hammer type, and will only allow, even under the most favourable conditions, about 40 makes and breaks per second. It is not adapted for rapid movement with very large currents, and could not be used for long-distance spark telegraphy.

Under these circumstances a suitable interrupter would be one in which the reciprocating is replaced by a rotating action, and the mercury contact still taking part in this. A suitable type of such a mechanism has been designed by the Allgemeine Elektricitäts-Gesellschaft, of Germany, which they call a "turbine interrupter," a section of which

Digitized by Google

is shown in Fig. 4. It is rather complicated in construction, yet simple in its action, and admirably meets the requirements. Referring to Fig. 3, the metal tube, *t*, is bent at a right angle, the lower part of the vertical arm dipping in mercury, and the mercury being covered with a layer of alcohol in a sufficient quantity so that the horizontal arm is surrounded with it. The lower part of the tube, *t* (see Fig. 4), is in the shape of a turbine wheel, and if the tube be made to turn rapidly about the axis of its vertical arm suction takes place, and the mercury is drawn up the tube, and is, owing to centrifugal force, discharged at the end of the horizontal arm in the form of a heavy jet. A

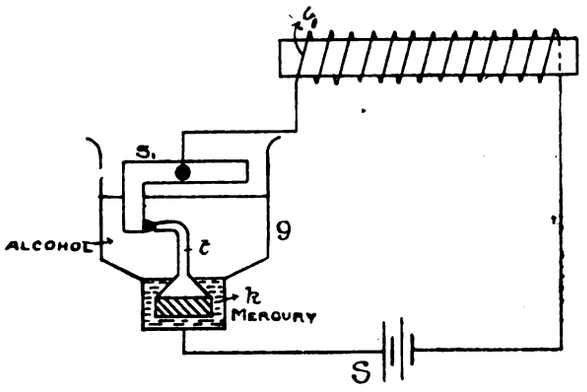

FIG. 3

metal ring, s_1, made with a segment, is placed concentrically to the shaft of the turbine. The segment projects downwards, and is under the surface of the alcohol, but not touching the surface of the mercury, so that the primary circuit is made as soon as the jet of mercury during its rotary motion comes in contact with this segment, and the duration of the contact is a very small interval of time, and decreases with the speed of the turbine; thus the make and break of the primary circuit is effected. The current passing from the battery, S, to the primary, *b*, the metal ring, s_1, the mercury, *k*, and metal tube, *t*, back to S. The idea of the layer of alcohol is to prevent any arcing, which would otherwise take place between the mercury jet and the metal segment. The number of makes and breaks can easily be made to vary between 1,000 and 10,000 per second, according to the speed of the turbine, and also the number of segments the ring, s_1, may have, which may be from one to four, according to the diameter of the ring. The whole of the body and cover of the apparatus is of cast iron, owing to the mercury not amalgamating to this metal.

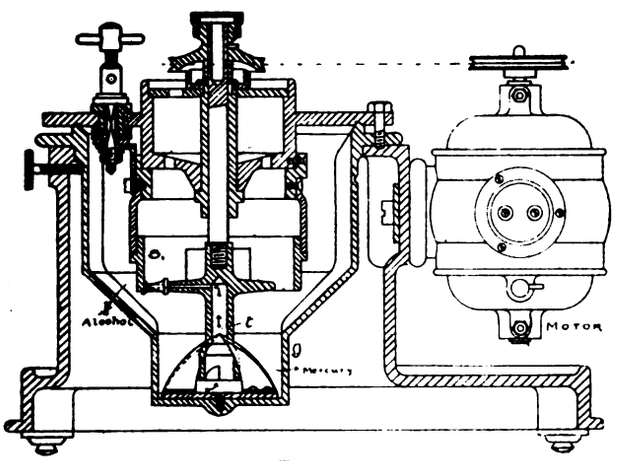

FIG 4.

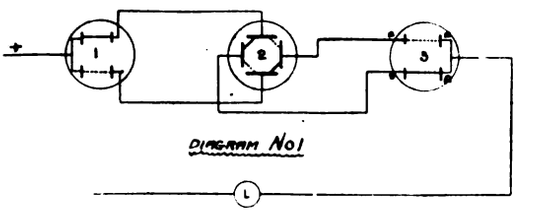
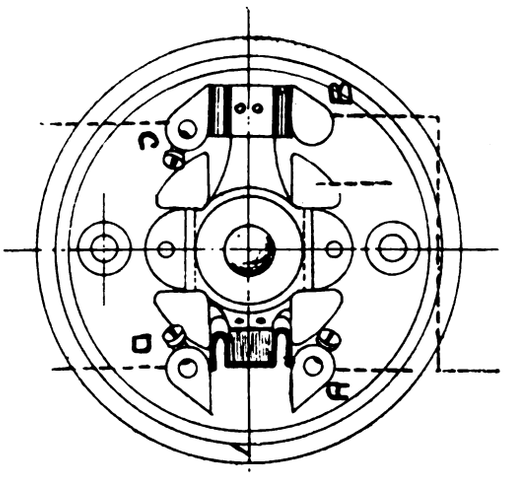
This turbine interrupter is driven by a cord transmission from a small electric motor fitted on the body of the interrupter. In the writer's opinion, this type of make and break for coils of large capacity is one of the best which has been invented, owing to the simplicity of its action and the absence of the expensive metal, platinum, and the great range of periodicity. The only disadvantage which is worth considering is the prime cost, and even this might be reduced if the apparatus were made less elaborate. However, this type of interrupter would save the cost of buying new platinum heads for the ordinary hammer type.—H. R. GREENYER.

Question No. 610.—Show diagrammatically the simplest method of controlling a single incandescent lamp from three places independently. Also give a sketch of the switches used for the purpose.

Answer to No. 610 (*awarded* 7*s.* 6*d.*).—I think the diagram below (No. 1) explains a good method of controlling a single incandescent lamp from three independent points. Nos. 1, 2, and 3 are the separate switches or

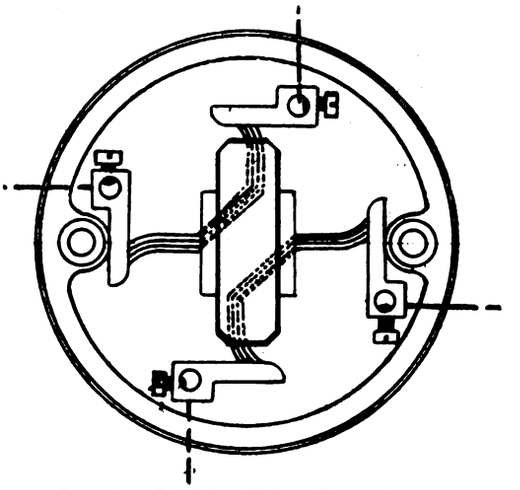


controlling points, and the dotted lines show the passage of current when in the other position. The switches 1 and 3 are of the two-way tumbler type, having no "off" position, as shown in plan herewith, and the intermediate



No. 1 AND 3.—Plan of Switch with Cover Removed. Terminals A and B Connected Together.

switch (No. 2) is of a different type, being a turn switch, although it is like a tumbler switch in the external appearance except for the ebonite handle. This switch also has no "off" position, as shown in plan herewith. A good switch for this purpose (No. 2) is made by the General Elec-



Plan of No. 2 Switch with Cover Removed.

tric Company, who call it the "Hydra" switch. If these "Hydra" switches cannot be readily obtained, another way out of the difficulty would be to use for the intermediate point two two-way switches, same as Nos. 1 and 3, coupled together by a fibre bar, and mounted on a two-way block and connected as shown in No. 2 diagram, thus keeping the switches all of the same type. The General Electric Company also list a "Hydra" two-way switch of the same pattern, which, if desired, could be used for Nos. 1 and 3 points instead of the switches shown. As all the

Digitized by Google

switches are on one pole, there is no danger of a short-circuit occurring. One or a group of lamps may be easily

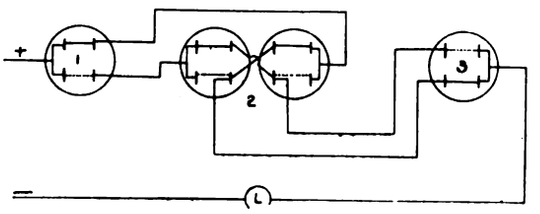


DIAGRAM No. 2.—Connections Show Lamp Alight.

controlled from any number of points by the use of extra intermediate switches.—PETER P. DEAN.

Answer to No. 610 (*awarded 7s. 6d.*).—In order to control an incandescent lamp from three points independently, two types of switch must be used. Those at the extreme points of the system, to which the leads from the main and lamp are connected, must be two-way switches; whilst the third

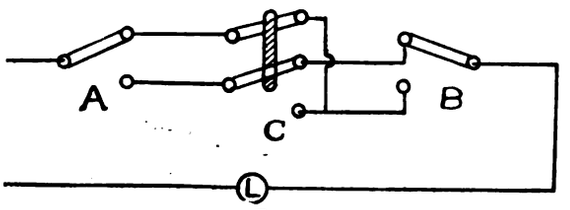

FIG. 1.

switch, connected between the above, must be of the change-over type. The connections necessary for carrying out this control are given in Fig. 1. By tracing out these connections it will be seen that the lamp, L, or a group, if necessary, can be switched on or off from either of the switches A, B, or C. A and B are ordinary two-way

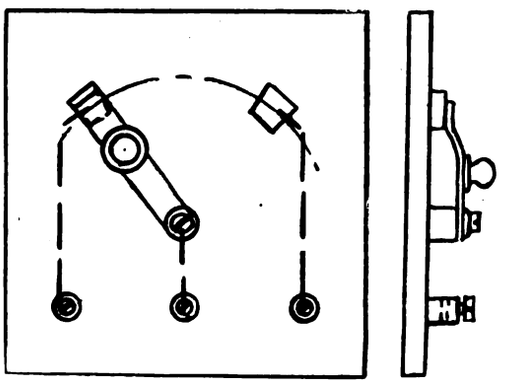

FIG. 2.

switches, whilst C has two contact arms, coupled mechanically, working on three contacts, two of which are connected together. The two-way switches may be of the simple lever pattern, as Fig. 2. They can also be obtained with either a "tumbler" or rotary action, both types being provided with a quick break. The change-over switch may also be of the lever form, as Fig. 3, this being similar to

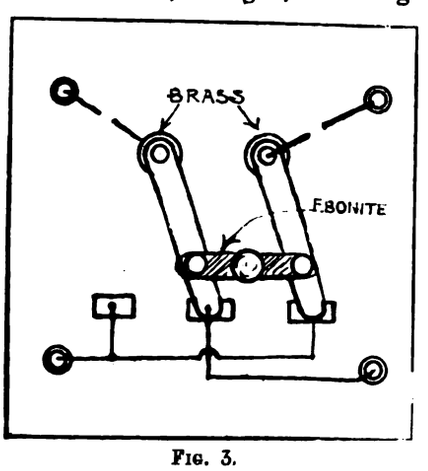

FIG. 3.

the type of switch supplied with small Rhumkorff coils for current reversal. The switch can be obtained with a rotary action, as Fig. 4, this type being provided with a quick break, not shown in sketch. Messrs. Verity's, I

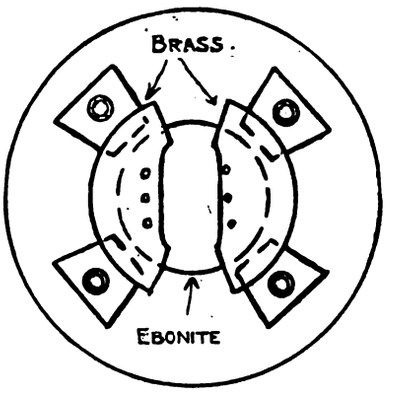

FIG. 4.

believe, manufacture a switch which enables a lamp to be controlled from any number of points independently. In this case, also, simple two-way switches are used at each end of the system.—F. T. C.

Answer to No. 610 (*awarded 7s. 6d.*).—The simplest way for "R. H. G." to control a single incandescent from three places independently is first to obtain two two-way switches

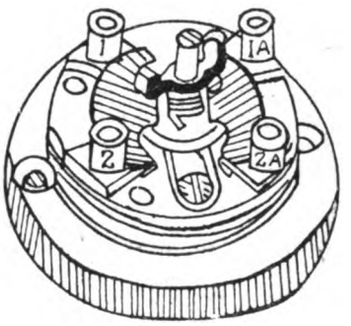

FIG. 1

and one variable-circuit switch. The types of switches required would be as described in sketches Figs. 1 and 2 The system here described has been carried out in dozens

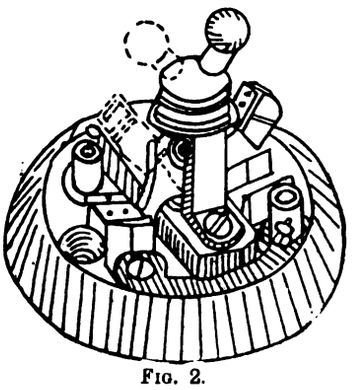

FIG. 2.

of cases by the writer, which is both practical and simple. In many cases, what is simple to one might appear the most complicated to another. As will be seen from Fig. 1,

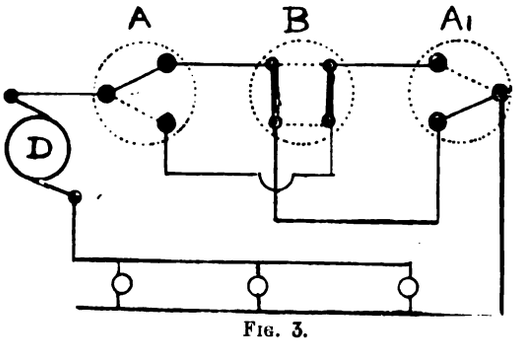

FIG. 3.

there are four terminal plates held in position by four binding terminals. This switch has both right and left

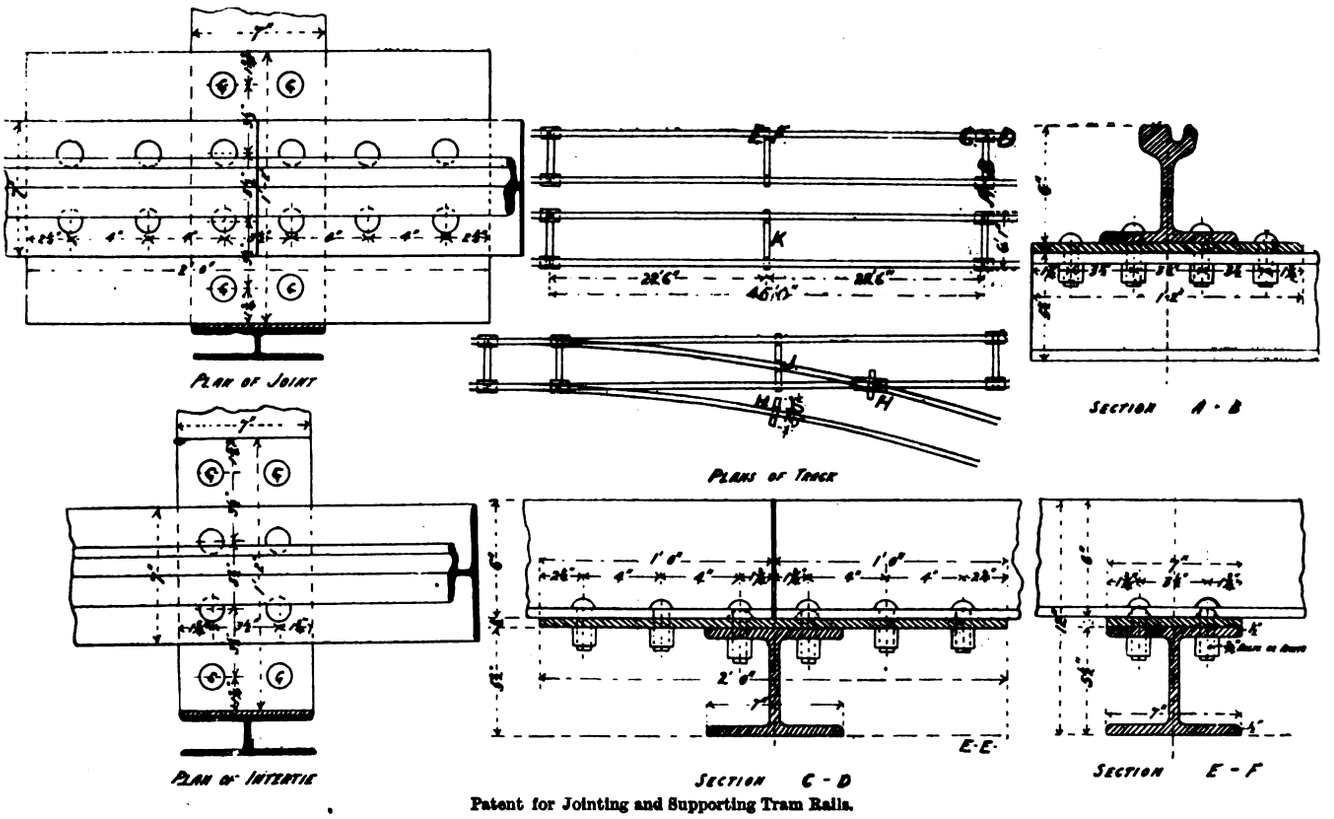
Digitized by Google

handed movements. The object of this is to short-circuit any two terminal plates. As in Fig. 1, contact is made at the points 1 and 2, also 1A and 2A, with a left-handed movement the positions taken up on the terminal plates would be 1 and 1A, also 2 and 2A. These consecutive movements switch the lamp on or off. Fig. 2 is an ordinary two-way tumbler switch, which is too well known to require description here. Diagram 3 illustrates all necessary connections; A and A_1 are the two-way switches, and B the variable-circuit switch. The connections show the lamps as being switched on, but a reversal of any switch will extinguish them. By using the variable-circuit switch for the intermediate positions and the two-way for the outer positions, a light or lights can be controlled from an indefinite number of points.—H J. G.

PATENT FOR JOINTING AND SUPPORTING TRAMRAILS.

We are indebted to Mr. W. C. Sample, a member of the city surveyor's staff, Sheffield, for the following particulars of a patent method of jointing and supporting tramrails for which provisional protection has been obtained.

It is claimed by the patentees that the adoption of their method will render the use of fishplates and tie-bars unnecessary, and will prevent the vibration so common in tramrails laid according to present methods, which is so detrimental to the wear of the rails, and cause the displacement and consequent expense in the maintenance and repair of the paving. It will also secure greater uniformity of track than is possible under present conditions, as the transverse girder embedded in concrete will secure the one rail firmly to the other.



Patent for Jointing and Supporting Tram Rails.

The patent consists of a transverse girder passing between and under the tramrails, and carrying two plates. The plates in turn support and are secured to the tramrails at the joints and also at the centre of the rails, which may be of any length and laid to any gauge. The plates on the transverse girder will be bolted or riveted to same at the points marked G on plan, and will be so fixed before arrival on the site of the works. The necessary bolt or rivet holes will be drilled or punched in the plates, girders, and tramrails in their correct positions at the works, so that the drilling of further holes on the site of the works will be rendered unnecessary. In double junctions and on curves where the joints of the tramrails do not come opposite one another the transverse girders can, if necessary, be shortened (as shown at H on plan), though this will be avoided as much as possible, and the transverse girder carried from rail to rail. Cases will occur in which the plates to carry points and rails will vary in shape and size, and in which the transverse girder will have to carry more than two plates and rails (as shown at J on plan), but the patent will be equally applicable to these and similar cases.

Justice needs that both be heard."

REPULSION MOTOR.

SIR,—In his article on a "New Single-Phase Motor" in your current issue, Herr L. Schüler describes as the subject of a recent English patent a type of machine which is started as a repulsion motor and converted during running into an induction motor by three slip-rings with resistances between them, which are gradually cut out. It will interest your readers to learn that nearly three years ago I introduced this very device for the same purpose on an experimental motor at the Central Technical College.—

Yours, etc. WILLIAM CRAMP, A.M.I.E.E.,
Lecturer on Electrical Design.

Central Technical College, S.W., Sept. 8, 1903.

APPOINTMENTS VACANT.

Engineer-in-Charge, Darlington Corporation, £78 per annum, 14th inst.

Designer, well up in both alternating and continuous currents. See advertisement in last issue.

Resident Engineer, Morecambe Borough Council, £150, rising to £200, Sept. 14.

Second Engineer-in-Charge, Bermondsey Borough Council, £125, Sept. 15. See advertisement in last issue.

Switchboard Attendant, Aston Manor Urban District Council. Sept. 18. See advertisement.

Assistant Instructor, City and Guilds of London Institute, salary commencing at £150. See advertisement.

Electrical Engineer for mine work abroad. See advertisement.

Bound Volumes of "THE ELECTRICAL ENGINEER," containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume, January to July, 1903, now ready.

THE BRITISH ASSOCIATION.

The annual meeting of the British Association for the Promotion of Science is again with us, and this year Southport is the favoured town to be invaded by scientific experts. It is to be hoped that the benefits conferred by this choice of a meeting place will be mutual, and that Southport will give in health a fair return for what it receives in enlightenment. The meeting was opened on Wednesday last with a most able address by Sir Norman Lockyer, in which a strong appeal is made for organising national scientific effort. The president attributes to the lack of scientific knowledge in this country our present backward position as compared with our neighbours in industrial progress. With the increased stress of competition with other manufacturing nations, he claims that it is only by organising on a national scale our scientific efforts that we can maintain our position and be amongst the countries to survive. His advocacy of a practical step to be taken is in the direction of increasing the number of our universities and their equipment. As will be seen from a condensation of the address in this issue, he treats the matter in the same way that our navy was treated in 1888 in order that we might maintain our supremacy on the high seas. Sir Norman Lockyer asks from the Government the modest sum of twenty-four millions sterling to build, equip, and endow eight new universities in the United Kingdom, but we are afraid that in the present state of politics there is little hope that the influence of the members of the British Association will be able to abstract such a sum from the custodians of the national exchequer. The arguments as to our relative position with Germany and the United States as regards means of education, deal with the subject in a more general way than was done in the presidential address delivered by Dr. John Perry before the Mechanical Section last year. The addresses in the individual sections this year are highly interesting. The one which mostly concerns our readers is that delivered by Mr. Charles Hawkesley before Section G. In this a good *résumé* is given of progress made in various departments of applied engineering. An interesting fact which may not be generally known is that Sir Frederick Bramwell has organised a paper to be read on prime movers at the meeting of the British Association in 1931. It was in 1881 that Sir Frederick predicted at York that the steam-engine as known at the present day would become a thing of the past, and that fifty years from then he doubted whether those who would gather together at the 1931 meeting would speak of the steam-engine except as in the nature of a curiosity to be found in the museum. This opinion is to form the text of the paper in 1931, and Sir Frederick left fifty pounds for investment in 2½ per cent. cumulative consols, the resultant sum to be paid to the author of the paper. In the same address a full description is given of progress in the electrical equipment of railways and of the good work which the railways operated by electricity are doing at the present time. The last part of the address deals with the question of water supply, of which its author is one of our greatest experts. For originality, however, the address before the Mathematical and Physical Section, read by Prof. Chas. Vernon Boys, takes, perhaps, the leading position this year. In it he speaks in the following way of the discovery of radium and its properties: "Of the events of the last year one stands out beyond all others, not only for its intrinsic importance and revolutionary possibilities, but for the excitement that it has raised among the general public. The discovery by Prof. and Madame Curie of what seems to be the everlasting production of heat in easily measurable quantity by a minute amount of a radium compound is so amazing, that

Digitized by Google

even now that many of us have had the opportunity of seeing with our own eyes the heated thermometer, we hardly are able to believe what we see. This, which can barely be distinguished from the discovery of perpetual motion, which it is an axiom of science to call impossible, has left every chemist and physicist in a state of bewilderment. Added to this, Sir William Crookes has an experiment, characteristic of him, if I may say so, in which a particle of radium keeps a screen bombarded for ever, so it seems, each collision producing a microscopic flash of light, the dancing and multitude of which forcibly compel the imagination to follow the reasoning faculties, and realise the existence of atomic tumult. Thanks to the industry and genius of J. J. Thomson, Rutherford, and Soddy, Sir William and Lady Huggins, Dewar, and Ramsay, and others in this country, besides Prof. and Madame Curie and a host of others abroad, this mystery is being attacked, and theories are being invented to account for the marvellous results of observation; but the theories themselves would a few years ago have seemed more wonderful and incredible than the facts, as we believe them to be, do to-day. An atom of radium can constantly produce an emanation. That is something like a gas, which escapes and carries with it wonderful properties; but the atom, the thing which cannot be divided, remains, and retains its weight. The emanation is truly wonderful. It is self-luminous, it is condensed by extreme cold and vaporises again, it can be watched as it oozes through stop-cocks or hurries through tubes, but in amount it is so small that it has not yet been weighed. Sir William Ramsay has treated it with a chemical cruelty that would well nigh have annihilated the most refractory or permanent known element, but this evanescent emanation comes out of an ordeal undimmed and undiminished." In the conclusion of this address Prof. Boys speaks favourably of the change which is being brought about in our public school life by the introduction of scientific instruction. From these addresses and from the programme which appears elsewhere in this issue, it will be gathered that the 1903 meeting of the British Association is likely to be a remarkable one in an already brilliant record.

THE BRITISH ASSOCIATION.

Under favourable auspices the seventy-third session of the British Association for the Promotion of Science was opened at Southport on Wednesday night, under the presidency of Sir Norman Lockyer, K.C.B., LL.D., F.R.S. Prior to the evening assembly, at which the president's inaugural address was delivered, the General Committee held a meeting, when Prof. Dewar, the retiring president, announced that the council of the association are in favour of accepting the invitation to hold the 1905 convention in South Africa. He stated that the Governments of the South African Colonies have undertaken to make a grant of £6,000 towards the expenses, and that the directors of the Union Castle Line have been equally generous in agreeing to a reduction of 30 per cent. in the fares to South Africa for officials and 25 per cent. for other members of the association. Prof. Dewar also announced that Mr. Balfour, the Prime Minister, has consented to his nomination as president for 1904, when the association meets at Cambridge.

Following we are able to give a *résumé* of the principal arrangements in several of the sections as provisionally fixed.

SECTION G (ENGINEERING).

THURSDAY, SEPT. 10, 11.30.—President's Address; C. A. Brereton, "King Edward VII. Bridge over the River Thames between Brentford and Kew"; J. Harrison, "Illustration of Graphical Analysis."

FRIDAY, SEPT. 11, 10 A.M.—J. H. Reynolds, "The Equipment of the Manchester Municipal Technical Institute"; "Report of the Committee on the Resistance of Road Vehicles to Traction"; T. Clarkson, "Steam Traction on Common Roads"; Lieut.-Colonel Crompton, "The Problem of Modern Street Traffic — opening a General Discussion on the Subject."

SATURDAY, SEPT. 12.—The section will not sit. Excursions to the Manchester Institute of Technology, the Westinghouse Company's works at Trafford Park.

MONDAY, SEPT. 14, 10 A.M.—"The Report of Committee on Small Screw Gauges"; J. Campbell Brown, "On the Nature and Quality of some Potable Waters in South-West Lancashire"; W. B. Woodhouse, "Protective Devices for High-Tension Electric Systems"; J. B. C. Kershaw, "Aluminium as an Electrical Conductor"; E. Wilson, "The Electrical Conductivity of certain Aluminium Alloys as affected by Exposure to London Atmosphere"; E. Wilson, "A Method for Finding the Efficiency of Series Motors"; B. Hopkinson, "The Parallel Running of Alternators"; W. Cramp, "The Single-Phase Repulsion Motor"; J. N. Shoolbred, "Electric Traction"; W. J. Goodrich, "Twenty-five Years' Progress in Final and Sanitary Refuse Disposal."

TUESDAY, SEPT. 15, 10 A.M.—F. B. Behr, "High-Speed Express Monorails and the Manchester and Liverpool Express Railway"; A. M. Bell, "Liquid Fuel"; J. Parry, "Water Supply of South-West Lancashire"; H. R Mill, "Rate of Fall of Rain at Seathwaite"; J. M. Shoolbred, "Tidal Regimé in the Mersey"; R. Pearson, "History of the Discovery of Natural Gas in Sussex"; G Forbes, "Further Experiences with the Infantry Range Finder."

WEDNESDAY, SEPT. 16, 10 A.M.—J. Aitken, "A Few Remarks on the Effect of Traffic and Weather on Macadamised Roads"; E. J. Izod, "Pendulum Apparatus for Testing Steel as regards Brittleness"; C. H. Wingfield, "Permanent Set in Cast Iron as bearing on the Design of Piston-Ring Springs"; H. E Wimperis, "A Further Note on Gas-Engine Explosion"; J. W. Thomas, "Ventilation of Tube Railways"; W. Odell, "Preliminary Experiments of Air Friction"; L. Bairstow and A. D. Alexander, "Experiments in Gas Explosions"; J. Morroco, "A New Form of Mirror Extensometer"; W. G. Popplewell, "Smoke Abatement."

SECTION A (MATHEMATICAL AND PHYSICAL SCIENCE).

THURSDAY, SEPT. 10, 10 A.M.—Address of Mr. C. V. Boys, F.R.S., president of the section; Lord Kelvin, "On Electrotherial Theory of the Velocity of Light in Gases, Liquids, and Solids"; 11 a.m., Prof. J. Rutherford, "On the Nature of the Emanations from Radioactive Substances" (discussion, in which Lord Kelvin, Principal Sir Oliver Lodge, Drs. Elster and Geitel, Prof. Schuster, Prof. J. J. Thomson, Prof. Dewar, Mr. Soddy, Prof. Armstrong, and C. T. R. Wilson will take part.)

FRIDAY, SEPT. 11, 10.30 A.M.—Address of Dr. W. N. Shaw, chairman of the department for astronomy and meteorology, "Methods of Meteorological Investigation"; Sir N. Lockyer, "On Simultaneous Solar and Terrestrial Changes"; Prof. A. Schuster, "Cosmical Rodioactivity" (discussion of two preceding papers); Dr. A. Buchan, "On the Relation of the Rainfall of Scotland to the Sunspot Periods, 1855-98"; Prof. J. M. Pernter, "Observations sur la Radiation aux Observatoires principaux"; Prof. Hildebrandsson, "On the General Circulation of the Atmosphere"; Prof. H. L. Callendar, "On Self-Recording Instruments"; Dr. K. Grossman and J. Lomas, "On the Origin and Forms of Hoar Frost, with Lantern Illustrations"; J. Swinburne, "On the Treatment of the Thermodynamics of Irreversible Processes" (discussion in which Prof. J. Perry will take part); J. E. Petavel, "On the Explosive Pressure and Rate of Combustion of Cordite"; R. T. Glazebrook, "Report of Committee on Electrical Standards"; G. Beilby, "On Granular Structure in Solids."

MONDAY, SEPT. 14, 10.30 A.M.—The section will meet in two departments.

Department of Pure Mathematics.

Harold Hilton, "On Spherical Curves"; W. H. Young, "On the Classification of Discontinuous Functions and the

Digitized by Google

Distribution of their Points of Continuity"; Lieutenant-Colonel A. Cunningham and H. J. Woodall, "On Primes."

Department of Astronomy and Meteorology.

Prof. H. H. Turner, "Was the New Star in Gemini shining previously as a very faint star?" J. Milne, "Report of the Seismological Committee"; D. Burns, "Phenomena accompanying the Volcanic Eruptions in the West Indies"; J. Milne, "The Inside of the Earth"; A. R. Hinks, "Exhibition of Photographs from Yerkes Observatory"; Dr. W. J. S. Lockyer, "Relation between Prominences, Sunspots, and Coronæ"; "Report of the Kite Committee"; A. L. Rotch, "Kite Observations at Blue Hill, 1900 2," with discussion; Prof. A. Schuster, "Radiation from a Foggy Atmosphere"; Dr. A. Buchan, "Diurnal Variation of Temperature in the Levant and its Relation to Radiation"; Dr. W. J. S. Lockyer, "Spectra of Lightning."

TUESDAY, SEPT. 15, 10.30 A.M.—"Report of the Committee on Underground Temperature"; "Report of the Committee on Solar Radiation"; R. S. Hutton and J. E. Petavel, "Note on Carbon and Iron Arc Spectra at High Gaseous Pressures"; Prof. R. A. Sampson, "Eclipse Observations of Jupiter's Satellites: A Study of the Ordinary Observations in Comparison with the Photometric Observations of Harvard"; Rev. A. L. Cortie, "Solar Prominences and Terrestrial Magnetism"; Dr. A. Schuster, "Wave Propagation in a Dispersive Medium." 12.30 p.m.—Prof Henrici, "On the Use of Vectorial Methods in Physics, Vector Algebra being the Natural Form of Mathematics for Expressing Relations between Physical Quantities" (discussion). There will be an open meeting of the International Meteorological Committee to discuss hours of observation and international telegraphy.

WEDNESDAY, SEPT. 16, 10.30.—"Report of Falmouth Observatory Committee"; Prof. J. M. Pernter, "Emploie de l'Hygrometre à cheveu au lieu du Psychrometre"; Dr. A. Buchan, "Report of the Ben Nevis Committee"; A. L. Rotch, "A Study of Audibility as affected by the Meteorological Conditions at Blue Hill during 1901"; H. R. Mill, "Mean Rainfall"; Prof. E. W. Marchant and G. W. Worrall, "On the Use of Capacities as Multipliers for Electrolytic Voltmeters in Alternating-Current Circuits"; P. H. Powell, "Considerations of Some Points in the Design and Working of Ballistic Galvanometers."

SECTION F (ECONOMIC SCIENCE AND STATISTICS).

THURSDAY, SEPT. 10.—Presidential address of E. W. Brabrook, chief registrar of friendly societies.

FRIDAY, SEPT. 11.—Discussion on "The Wealth of the Country and what should be done with it," opened by Sir Robert Giffen.

MONDAY, SEPT. 14.—Papers and discussion on the economic aspects of the fiscal controversy as follows: Dr. E. Cannan, "Modern Economics and Free Trade"; Prof. W. Cunningham, "Failures to Attain the Ideals of Free Traders"; A. L. Bowley, "Statistical Methods and the Fiscal Controversy,"; B. Etlinger, "Comparative Statistics of our Trade with our Colonies, U.S.A., and the Protected Countries of Europe"; and probably papers on "History of Retaliation," "History of Commercial Relations with Canada," and "Statistics on Production."

THURSDAY.—Final report of committee on "The Economic Effect of Legislation Regulating Women's Labour"; Mrs. Bosanquet, "Physical Deterioration and the Poverty Line."

The following other papers will probably also be read before this section: S. H. Turner, "Depreciation and Sinking Funds in Municipal Undertakings"; Dr. Ginsburg, "The Growth of Rates"; also a paper on "Garden Cities."

SECTION L (EDUCATIONAL SCIENCE).

THURSDAY AND FRIDAY, SEPT. 10 AND 11.—Discussion on "School Curricula," based on a series of short papers. Introductory papers have been promised by Miss Burstall and M. E. Sadler, J. L. Paton, W. L. Fletcher (Liverpool Institute), John Adams, T. E. Page, and others. A joint meeting with the Geographical Section will be held to discuss the "Teaching of Geography." In addition to the above subjects, there will also be discussions on the reports of committees on the conditions of health essential to the carrying on of the work of instruction in schools; the teaching of natural science in elementary schools; the influence exercised by universities and examining bodies on secondary school curricula, and also of the schools on university requirements; the teaching of botany in schools.

On Saturday, the 12th, at 8 p.m., Dr. J. S. Flett, London, will deliver a lecture to working-men on the subject of "Martinique and St. Vincent: The Eruptions of 1902," with lantern slides.

Among the many diverting and instructive excursions which have been arranged in connection with the meeting are the following, which we think will particularly appeal to members of the engineering profession: On Saturday, the 12th, the place of visit is Manchester, where, among others, the works of the British Westinghouse Company will be open to inspection. The members of the party, which, by the way, is limited to 250, will have an opportunity of expressing an opinion on the electric tramway system of the city, as the arrangements provide for two car rides in the direction of Trafford Park. Lunch will be partaken of at the Westinghouse works, and the excursion will occupy the whole day. On Wednesday, the 16th, a visit to Port Sunlight to inspect Messrs. Lever Bros.' soap works and model village, and to Liverpool for the Diamond Match Works should prove of interest, but in each case the number of the party is limited. The British Insulated and Helsby Cables, Limited, have invited a party not exceeding 100 to visit their works at Prescot for Thursday, the 17th, and on the same day an opportunity will be given to visit a couple of coal pits—the Hulton Park coal pit at Atherton and the Abram coal pit, near Wigan. Among other places of engineering interest which will be opened to inspection during the week are the Blowick Electricity Works; the works of Messrs. Dobson and Barlow, Limited, machine makers and engineers, Bolton; the Manchester Municipal School of Technology; the ss. "Lucania," Liverpool; and the L. and Y. Railway Company's works, Horwich.

RADIUM AND OTHER RADIOACTIVE SUBSTANCES WITH A CONSIDERATION OF PHOSPHORESCENT AND FLUORESCENT SUBSTANCES. THE PROPERTIES AND APPLICATIONS OF SELENIUM AND THE TREATMENT OF DISEASE BY THE ULTRA-VIOLET LIGHT.*

BY WILLIAM J. HAMMER.

(Continued from page 357.)

It is well known that in the case of the radiophone, if a beam of sunlight be thus intercepted by a blackened perforated revolving disc, a musical note, varying in pitch with the speed of the disc, will be produced in a rubber tube held at the opposite side of the disc. I have here one of the original forms of radiophones. A piece of apparatus has been devised consisting of a disc with slits near the edge, which is placed near an incandescent lamp and a selenium cell. If the selenium cell is connected to a telephone and battery, and the disc is rapidly revolved, a musical note will be produced in the telephone, the pitch of which will correspond to the speed of the revolving disc. Mr. Giltay has recently written me suggesting a very pretty experiment in this line, in which a double-vaned Crookes radiometer is placed between a selenium cell and an arc light shielded by an alum cell. The light from the arc lamp causes the radiometer to revolve intermittently screening the selenium cell and producing a musical note in the telephone attached thereto, the pitch of which is in accordance with the speed of revolution of the radiometer. I have here to-night two forms of flame telephone transmitters, one of which was presented to me by Mr. Ruhmer, and the other I have purchased from Mr. Giltray, which I have mounted as you see it here and as illus-

* A lecture delivered at a meeting of the American Institute of Electrical Engineers and the American Electrochemical Society, New York, April 17, 1903.

Digitized by Google

trated in Fig. 20 (about 24 volts are required, depending upon the selenium cell). In each case you will note that I have an acetylene generator, which conveys gas to the interior of an otherwise empty telephone transmitter. The diaphragm of these transmitters is made of pigskin or a similar material. A tiny pipe runs from the back of the transmitter, and ends in one case to a single acetylene jet, and in the other case to three acetylene jets. By talking against the pigskin diaphragm the gas inside is made to vibrate, and produces a manometric flame. This flame throws its light upon a selenium cell, to which is connected a battery and a pair of very sensitive telephones between 100 and 200 ohms for each cell of battery, in which the sounds spoken into the transmitter are most perfectly reproduced. A thin sheet of paper inserted between the flame and the selenium cell serves to cut off all sound. It is self-evident that these telephone receivers might be at any distant point. I have worked them over considerable distances.

In Fig. 21 are shown a number of most interesting applications of the selenium cell in conjunction with a battery and relay, used for starting a motor, ringing a bell,

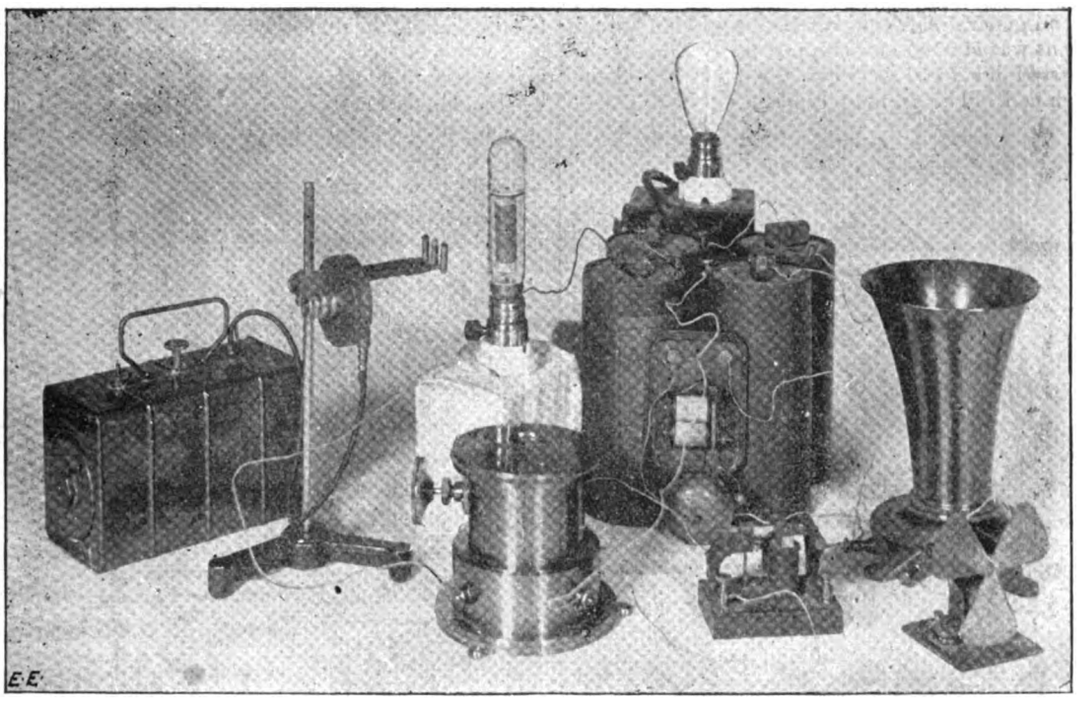

FIG. 21.—Acetylene Flame Apparatus, Ruhmer Selenium Cell, Relays and Battery for Operating, Electric Lamp, Bell, Motor, and Horn. (A 3-h.p. Motor and Generator were also similarly operated and a cannon fired).

firing a cannon, blowing a horn, and lighting incandescent lamps, all of which experiments I shall hope to show you in actual operation, as I have had them working most successfully in my laboratory; and you will see that by merely passing my hand before the selenium cell I can start and stop the motor, turn the light on and off, and ring the bell and blow the horn, or I can fire this cannon, start my phonograph talking, etc. I am indebted to the courtesy of the Marconi Company for the large relay used in certain of these experiments. I have here also a 3-h.p. motor driving a 1½-kw. generator and supplying these lamps which have been courteously supplied by the General

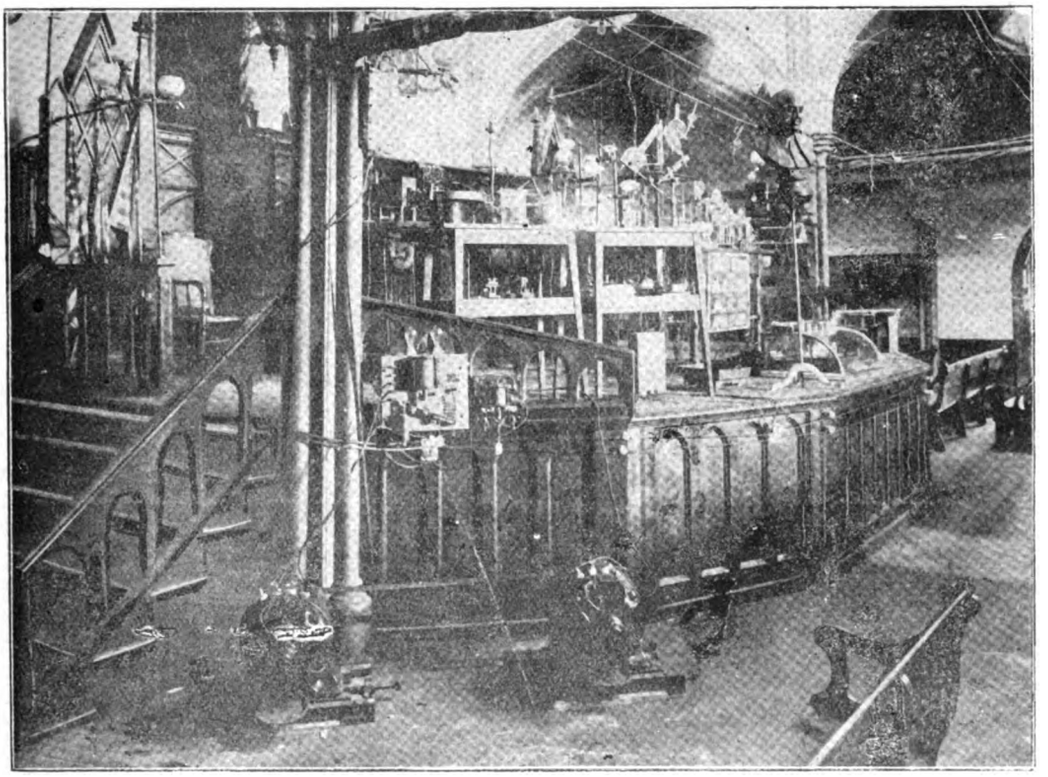

FIG. 22.—3-h.p. Motor and Generator supplying Bank of Lamps and operated by shielding with the hand a Selenium Cell from an Acetylene Flame.

Digitized by Google

Electric Company; and by means of this selenium cell, relay, battery, and a motor starter, for which I am indebted to the Cutler-Hammer Company, I hope to be enabled to start and stop the motor by merely passing my hand before the selenium cell. In Fig. 22 is shown a portion of the stage setting at the lecture, and shows in the foreground the 3-h.p. motor and generator which supplied a bank of lamps, and which plant was started and stopped many times when the author passed his hand between the acetylene flame and a selenium cell. The frontispiece is a general view of

FIG. 23.—Pintsch Gas Buoy controlled by a Ruhmer Selenium Cell, Battery, and Switch Mechanism.

the stage setting in the College of the City of New York, and was taken shortly before Mr. Hammer's lecture.

In 1886 the writer attended a convention of the Edison Association of Illuminating Companies at Rochester, New York, and during a discussion of contract systems *versus* meter systems, he gave his experience as chief inspector of central stations of the Edison Company in dealing with the difficulties met with in supplying light by contract; and he then described a practical method of utilising selenium cells to control relays and magnets which would

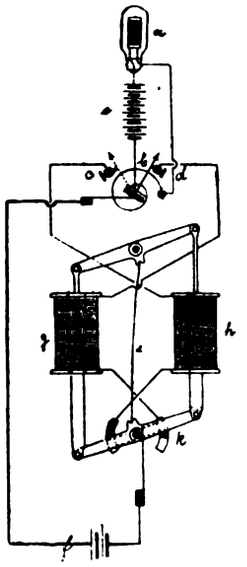

FIG. 24.—Diagram of Circuits of "Selenium" Buoy.

throw off the electric light on the approach of day and on again at night, thus solving the difficulty of street-lighting and other circuits intended to operate only at night. On Feb. 12, 1890, in a paper on some experiments with selenium cells, Mr. Shelford Bidwell showed a relay operated by a selenium cell, which threw on an electric lamp and rang a bell, and he suggested the protection of safes and strong rooms by selenium cells, which would be affected by the light from a burglar's lantern, thus giving an alarm. He also spoke of their being used to give notice of the extinction of railway signal lamps and ship lights, and stated the following: "But I do not at present attach any serious importance to such practical applications of these devices. I regard them simply as offering somewhat attractive illustrations of the effect of light upon the resistance of selenium." This is an important statement from the greatest authority on the subject of selenium, but to-day it will not hold good. I hold in my hand a small vial containing some "thermit," which was discovered by Dr. Goldschmidt. It consists of oxide of iron, such as one would get off of a blacksmith's anvil or from the

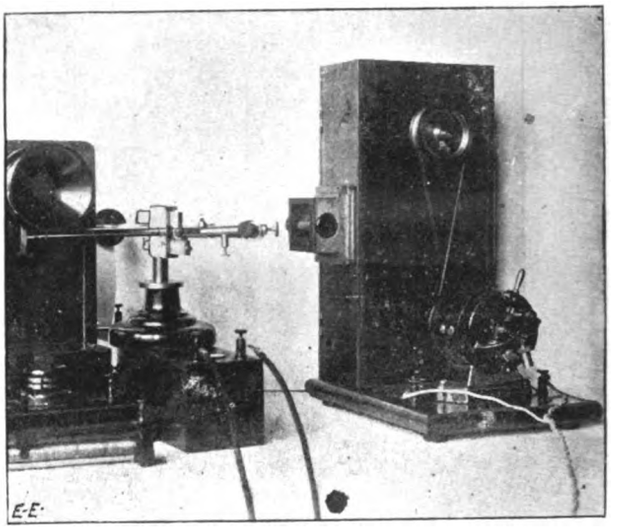

FIG. 25.—Ernest Ruhmer's Photographophone, showing Exterior View, together with Telephone Transmitter and Arc Lamp.

rolls of a rolling mill, and is mixed with powdered metallic aluminium. A red-hot iron or molten cast iron poured into this mixture produces no effect, but if a little barium preparation or magnesium powder be placed on top of this mixture and touched off by a match, an extraordinary reaction takes place, producing a temperature of about 3,000deg. C., and the mechanical equivalent of a kilo (2·2lb.) of thermit is about 1,730 horse-

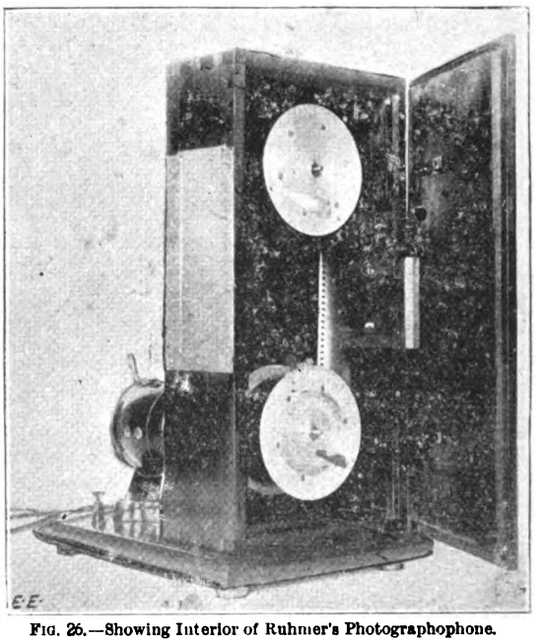

FIG. 26.—Showing Interior of Ruhmer's Photographophone.

power seconds, or 1,273 kilowatt-seconds. I have seen some very interesting experiments made in welding girder rails, pipes, etc., by this process, and have here some interesting samples of manganese, chromium, ferro-titanium, and other metals prepared in this way. I have also seen steel safes in which enormous holes had been burned by employing thermit, and it would be possible for a burglar to carry some thermit in his pocket and burn a hole in a safe large enough to insert his arm and extract the valuables. I also saw in Germany last summer

Digitized by Google

a substance called "anti-thermit," which it is intended to place in the lining of safes to prevent the reaction taking place, thus protecting the safe. But a simple plan would be to place a selenium cell in or near the safe, so that the moment the reaction was started a signal would be given to the police in a similar manner, as suggested by Mr. Bidwell in the case of the burglar's bullseye lantern. An important commercial application of the selenium cell has recently been made by Mr. Ernest Ruhmer in connection with his electrically controlled buoy illustrated in Fig. 23.

. Pintsch has constructed a large number of buoys containing compressed gas, which would last from one month to upwards of a year; but it was heretofore necessary to burn these lights day and night, it being often impracticable, by reason of distance at which they were placed and frequency of storms, etc., to switch off the gas so that it would not burn during the daytime. Mr. Ruhmer has placed one of his selenium cells in the top of such a buoy connected with a switching device, which, as soon as the sun rises in the morning, causes the selenium cell to reduce its resistance, this causing the switching device to turn off the gas, which is again turned on upon the increase of resistance of the selenium cell by the approach of nightfall, or if desired in the case of a storm coming up. A buoy containing sufficient gas for one month could thus be made to answer without recharge for from three to five months. The arrangements of the circuits as originally devised by Mr. Ruhmer is shown in Fig. 24. The voltmeter needle has been replaced by a relay, and the apparatus simplified. A single dry cell is interpolated in the selenium cell circuit, as usually employed on the buoy, and this cell will last a year or more.

(To be continued.)

FORTHCOMING EVENTS.

Municipal and County Engineers.—Meeting at Hastings on September 11 and 12.

British Association.—Seventy-third annual meeting, Sept. 9-17, Southport.

Sanitary Institute.—Sept. 16, lecture by Dr. E. J. Steegmann, "Natural Forces: Light, Heat, Electricity; Chemistry."

THE BRITISH ASSOCIATION.

The following is a somewhat abridged reproduction of the presidential address delivered by Sir Norman Lockyer, K.C.B., LL.D., F.R.S., correspondant de l'Institut de France, at Southport on Wednesday evening last. The President said:

"My first duty to-night is a sad one. I have to refer to a great loss which this nation and this association have sustained. By the death of the great Englishman and great statesman who has just passed away we members of the British Association are deprived of one of the most illustrious of our past-presidents. We have to mourn the loss of an enthusiastic student of science. We recognise that as Prime Minister he was mindful of the interests of science, and that to him we owe a more general recognition on the part of the State of the value to the nation of the work of scientific men. On all these grounds you will join in the expression of respectful sympathy with Lord Salisbury's family in their great personal loss which your council has embodied this morning in a resolution of condolence. Last year, when this friend of science ceased to be Prime Minister, he was succeeded by another statesman who also has given many proofs of his devotion to philosophical studies, and has shown in many utterances that he has a clear understanding of the real place of science in modern civilisation. We, then, have good grounds for hoping that the improvement in the position of science in this country which we owe to the one will also be the care of his successor, who has honoured the association by accepting the unanimous nomination of your council to be your president next year, an acceptance which adds a new lustre to this chair. On this we may congratulate ourselves all the more, because I think, although it is not generally recognised, that the century into which we have now well entered may be more momentous than any which has preceded it, and that the present history of the world is being so largely moulded by the influence of brain power, which in these modern days has to do with natural as well as human forces and laws, that statesmen and politicians will have in the future to pay more regard to education and science as empire builders and empire guarders than they have paid in the past.

"The nineteenth century will ever be known as the one in which the influences of science were first fully realised in civilised communities; the scientific progress was so gigantic that it seems rash to predict that any of its successors can be more important in the life of any nation. Britain in the middle of the last century was certainly the country which gained most by the advent of science, for she was then in full possession of those material gifts of Nature, coal and iron, the combined winning and utilisation of which, in the production of machinery and in other ways, soon made her the richest country in the world, the seat and throne of invention and manufacture, as Mr. Carnegie has called her. Being the great producers and exporters of all kinds of manufactured goods, we became eventually, with our iron ships, the great carriers, and hence the supremacy of our mercantile marine and our present command of the sea. The most fundamental change wrought by the early applications of science was in relation to producing and carrying power. With the winning of mineral wealth and the production of machinery in other countries, and cheap and rapid transit between nations, our superiority as depending upon our first use of vast material resources was reduced. Science, which is above all things cosmopolitan—planetary, not national—internationalises such resources at once. In every market of the world

> 'things of beauty, things of use,
> Which one fair planet can produce,
> Brought from under every star,'

were soon to be found. Hence the first great effect of the general progress of science was relatively to diminish the initial supremacy of Britain due to the first use of *material* resources, which, indeed, was the real source of our national wealth and place among the nations. The unfortunate thing was that, while the foundations of our superiority depending upon our *material resources* were being thus sapped by a cause *which was beyond our control*, our statesmen and our universities were blind leaders of the blind, and our other asset, our mental resources, which was within our control, was culpably neglected. So little did the bulk of our statesmen know of the part science was playing in the modern world and of the real basis of the nation's activities, that they imagined political and fiscal problems to be the only matters of importance. Nor, indeed, are we very much better off to-day. In the important discussions recently raised by Mr. Chamberlain next to nothing has been said of the effect of the progress of science on prices. The whole course of the modern world is attributed to the presence or absence of taxes on certain commodities in certain countries. The fact that the great fall in the price of food-stuffs in England did not come till some 30 or 40 years after the removal of the corn duty between 1847 and 1849 gives them no pause; for them new inventions, railways, and steamships are negligible quantities; the vast increase in the world's wealth, in free trade and protected countries alike, comes merely, according to them, in response to some *political* shibboleth. We now know, from what has occurred in other states, that if our Ministers had been more wise and our universities more numerous and efficient, our *mental resources* would have been developed by improvements in educational method, by the introduction of science into schools, and, more important than all the rest, by the teaching of science by experiment, observation, and research, and not from books. It is because this was not done that we have fallen behind other nations in properly applying science to industry, so that our applications of science to industry are relatively less important than they were. But this is by no means all; we have lacked the strengthening of the national life produced by fostering the scientific spirit among all classes and along all lines of the nation's activity; many of the responsible authorities know little and care less about science; we have not learned that it is the duty of a state to organise its forces as carefully for peace as for war; that universities and other teaching centres are as important as battleships or big battalions—are, in fact, essential parts of a modern State's machinery, and, as such, to be equally aided and as efficiently organised to secure its future well-being.

"Now the objects of the British Association as laid down by its founders 72 years ago are 'To give a stronger impulse and a more systematic direction to scientific enquiry—to promote the intercourse of those who cultivate science in different parts of the British Empire with one another and with foreign philosophers—to obtain a more general attention to the objects of science and a removal of any disadvantages of a public kind which impede its progress.' In the main, my predecessors in this chair, to which you have done me the honour to call me, have dealt, and with great benefit to science, with the objects first named. But at a critical time like the present I find it imperative to depart from the course so generally followed by my predecessors and to deal with the last object named, for unless by some means or other we 'obtain a more general attention to the objects of science and a removal of any disadvantages of a public kind which impede its progress,' we

Digitized by Google

shall suffer in competition with other communities in which science is more generally utilised for the purposes of the national life."

Sir Norman Lockyer proceeded to quote the opinions of our leading statesmen to show that our industries are suffering in the present international competition. Thus: "Mr. Chamberlain's views were stated in the following words: 'I do not think it is necessary for me to say anything as to the urgency and necessity of scientific training. . . . It is not too much to say that the existence of this country as the great commercial nation depends upon it. . . . It depends very much upon what we are doing now, at the beginning of the twentieth century, whether at its end we shall continue to maintain our supremacy, or even equality, with our great commercial and manufacturing rivals.' All this refers to our industries. We are suffering because trade no longer follows the flag as in the old days, but because trade follows the brains, and our manufacturers are too apt to be careless in securing them. In one chemical establishment in Germany 400 doctors of science, the best the universities there can turn out, have been employed at different times in late years. In the United States the most successful students in the higher teaching centres are snapped up the moment they have finished their course of training and put into charge of large concerns, so that the idea has got abroad that youth is the password of success in American industry. It has been forgotten that the latest product of the highest scientific education must necessarily be young, and that it is the training, and not the age, which determines his employment. In Britain, on the other hand, apprentices who can pay high premiums are too often preferred to those who are well educated, and the old rule-of-thumb processes are preferred to new developments—a conservatism too often depending upon the master's own want of knowledge."

This led to the consideration of the necessity for a body dealing with the organisation of science, and to the fact that the British Association was such a body. The President on this point said: "A careful study of the early history of the association leads me to the belief that the function I am now dwelling on was strongly in the minds of the founders; but be this as it may, let me point out how admirably the organisation is framed to enable men of science to influence public opinion and so to bring pressure to bear upon Governments which follow public opinion: (1) Unlike all the other chief metropolitan societies, its outlook is not limited to any branch or branches of science. (2) We have a wide and numerous fellowship, including both the leaders and the lovers of science, in which all branches of science are and always have been included with the utmost catholicity—a condition which renders strong committees possible on any subject. (3) An annual meeting at a time when people can pay attention to the deliberations, and when the newspapers can print reports. (4) The possibility of beating up recruits and establishing local committees in different localities, even in the King's dominions beyond the seas, since the place of meeting changes from year to year, and is not limited to these islands. We not only, then, have a scientific Parliament competent to deal with all matters, including those of national importance, relating to science, but machinery for influencing all new councils and committees dealing with local matters, the functions of which are daily becoming more important. The machinery might consist of our corresponding societies. We already have affiliated to us 70 societies, with a membership of 25,000. Were this number increased so as to include every scientific society in the Empire, metropolitan and provincial, we might eventually hope for a membership of half a million. We in this Empire certainly need to organise science as much as in Germany they find the need to organise a navy. The German Navy League, which has branches even in our Colonies, already has a membership of 630,000, and its income is nearly £20,000 a year. A British Science League of 500,000, with 6d. subscription, would give us £12,000 a year, quite enough to begin with. I for one believe that the British Association would be a vast gainer by such an expansion of one of its existing functions. Increased authority and prestige would follow its increased utility. The meetings would possess a new interest; there would be new subjects for reports; missionary work, less needed than formerly, would be replaced by efforts much more suited to the real wants of the time. This magnificent, strong, and complicated organisation would become a living force, working throughout the year instead of practically lying idle, useless, and rusting for 51 weeks out of the 52 so far as its close association with its members is concerned. If this suggestion in any way commends itself to you, then, when you begin your work in your sections or General Committee, see to it that a body is appointed to enquire how the thing can be done.

"There is another matter I should like to see referred to the committee I have spoken of, if it please you to appoint it. The British Association—which, as I have already pointed out, is now the chief body in the Empire which deals with the totality of science—is, I believe, the only organisation of any consequence which is without a charter, and which has not his Majesty the King as patron." The first work of such an organisation, in Sir Norman Lockyer's opinion, is that of providing better university teaching, more opportunities for research, and many more well-endowed universities. By comparison with Germany and the United States, we were lamentably behind in this matter, and the President attributed this largely to the small State aid afforded. Thus: "If we take the 12 English university colleges, the forerunners of universities unless we are to perish from lack of knowledge, we find that private effort during 60 years has found less than £4,000,000—that is, £2,000,000 for buildings and £40,000 a year income. This gives us an average of £166,000 for buildings and £3,300 for yearly income. In the United States, during the last few years, universities and colleges have received more than £40,000,000 from this source alone; private effort supplied nearly £70,000,000 in the years 1898-1900. Next consider the amount of State aid to universities afforded in Germany. The buildings of the new University of Strassburg have already cost nearly a million—that is, about as much as has yet been found by private effort for buildings in Manchester, Liverpool, Birmingham, Bristol, Newcastle, and Sheffield. The Government annual endowment of the same German university is more than £49,000. This is what private endowment does for us in England, against State endowment in Germany. But the State does really concede the principle; its present contribution to our universities and colleges amounts to £155,600 a year. No capital sum, however, is taken for buildings. The State endowment of the University of Berlin in 1891-2 amounted to £168,777. When, then, we consider the large endowments of university education both in the United States and Germany, it is obvious that State aid only can make any valid competition possible with either. To compete on equal grounds with other nations we must have more universities. But this is not all—we want a far better endowment of all the existing ones, not forgetting better opportunities for research on the part of both professors and students. The buildings of the most modern university in Germany have cost a million. For upkeep the yearly sums found, chiefly by the State, for German universities of different grades, taking the incomes of seven out of the 22 universities as examples, are: first class—Berlin, £130,000; second class—Bonn and Göttingen, £56,000; third class—Königsberg and Strassburg, £48,000; fourth class—Heidelburg and Marburg, £37,000. Thus, if Leeds, which is to have a university, is content with the fourth-class German standard, a rate must be levied of 7d. in the £ for yearly expenses, independent of all buildings. But the facts are that our towns are already at the breaking strain. During the last 50 years, in spite of enormous increases in rateable values, the rates have gone up from about 2s. to about 7s. in the £ for real *local* purposes. But no university can be a merely local institution."

Sir Norman Lockyer then called for an effort from the Government similar to that made in 1888, when it was found that our navy was getting insufficient to compare favourably with those of two rival States if combined together. That year £21,500,000 was voted for the navy. To bring our universities into line with those of our competitors only eight new ones were needed, and some £24,000,000 would be required for their construction and endowment. As to the question of how is this money to be raised, the President said: "I reply, with hesitation, *Duplicate the navy bill of* 1888-9; do at once for brain power what we so successfully did then for sea power. Let £24,000,000 be set apart from one asset, our national wealth, to increase the other, brain power. Let it be assigned and borrowed as it is wanted; there will be a capital sum for new buildings to be erected in the next five or ten years, the interest of the remainder to go towards increased annual endowments. There need be no difficulty about allocating money to the various institutions. Let each university make up its mind as to which rank of the German universities it wishes to emulate. When this claim has been agreed to, the sums necessary to provide the buildings and teaching staff of that that class of university should be granted without demur. It is the case of battleships over again, and money need not be spent more freely in one case than in the other. Let me at once say that this sum is not to be regarded as practically gone when spent, as in the case of a short-lived ironclad. *It is a loan* which will bear a high rate of interest. This is not my opinion merely; it is the opinion of those concerned in great industrial enterprises and fully alive to the origin and effects of the present condition of things.

"When dealing with our universities, I referred to the importance of research, as it is now generally acknowledged to be the most powerful engine of education that we possess. But education, after all, is but a means to the end, which, from the national point of view, is the application of old and the production of new knowledge. Its national importance apart from education is now so generally recognised that in all civilised nations except our own means of research are being daily more amply provided for all students after they have passed through their university career; and, more than this, for all who can increase the country's renown or prosperity by

Digitized by Google

the making of new knowledge, upon which not only commercial progress, but all intellectual advance must depend. Years ago we had Faraday apparently wasting his energies and time in playing with needles; electricity now fills the world. To-day men of science in all lands are studying the emanations of radium — no research could be more abstract, but who knows what advance in human thought may follow or what gigantic world-transforming superstructure may eventually be raised on the minute foundation they are laying? If we so organise our teaching forces that we can use them at all stages, from the gutter to the university, to sift out for us potential Faradays—to utilise the mental products which otherwise would be wasted—it is only by enabling such men to continue their learning after their teaching is over that we shall be able to secure the greatest advantage which any educational system can afford."

After dealing with the need of a Scientific National Council an able address was concluded in the following words:

"To sum up, then. My earnest appeal to you is to gird up your loins and see to it that the science of the British Empire shall no longer remain unorganised. I have endeavoured to point out to you how the nation at present suffers from the absence of a powerful, continuous, reasoned expression of scientific opinion, urging in season and out of season that we shall be armed as other nations are, with efficient universities and facilities for research to uphold the flag of Britain in the domain of learning and discovery, and which they alone can bring. I have also endeavoured to show how, when this is done, the nation will still be less strong than it need be if there be not added to our many existing councils another, to secure that even during peace the benefits which a proper co-ordination of scientific effort in the nation's interest can bring shall not be neglected as they are at present. Lest some of you may think that the scientific organisation which I trust you will determine to found would risk success in working on such large lines, let me remind you that in 1859, when the late Prince Consort occupied this chair, he referred to 'impediments' to scientific progress, and said, 'they are often such as can only be successfully dealt with by the powerful arm of the State or the long purse of the nation.' If the Prince Consort had lived to continue his advocacy of science, our position to-day would have been very different. His early death was as bad for Britain as the loss of a great campaign. If we cannot make up what we have lost matters cannot mend. I have done what I feel to be my duty in bringing the present condition of things before you. It is now your duty, if you agree with me, to see that it be put right. You can if you will."

TRADE NOTICES AND NOVELTIES.

"Luna" Nernst Lamps.

A new type of Nernst lamp, called the "Luna," intended more especially to take the place of small arcs, is being introduced by the Electrical Company, Limited, 122 and 124, Charing Cross-road, London, W.C. The feature chiefly remarkable about this lamp is its very high efficiency. The one-ampere 100-volt size has a candle-power of 105, while the sizes taking one ampere at 250 volts, two amperes at 100 volts, and two amperes at 150 volts, yield respectively about 285 c.p., 210 c.p., and 320 c.p. In other words, the "Luna" Nernst lamp consumes less than one watt per candle-power. The principal improvement which the lamp combines is a new form of burner, the construction of which is shown in one of the illustrations herewith. By the use of a flat heating coil the partial screening of the light, which was unavoidable with the helical form of coil hitherto employed, is eliminated, and the efficiency of the burner thus increased. Among the other advantages claimed for the "Luna" Nernst over small arc lamps may be mentioned better diffusion of light, suitability for any direct-current voltage between 100 and 260, longer life, and low initial cost. At present, we understand, this lamp can be supplied for direct current only.

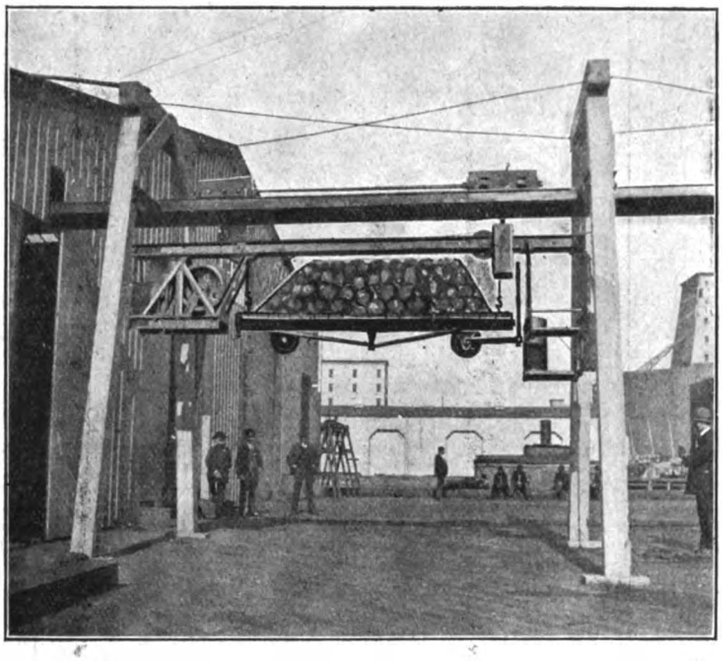
Telpherage in Goods Yards.

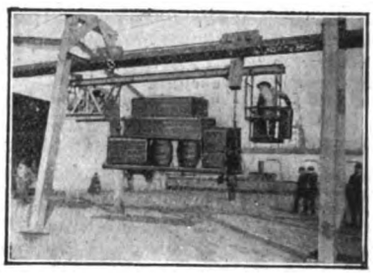
The above question is dealt with in Circular 104 issued by Messrs. Siemens Bros. and Co., Limited. The system described is one which lends itself to many useful applications, and will doubtless come rapidly into vogue for the purpose which it is primarily intended to fulfil—namely, the handling of miscellaneous goods at terminal stations. The accompanying illustrations are reproduced from this circular, to which we are also indebted for the following explanatory matter. It is well known that one chief source of expense in connection with goods traffic arises from the fact that on the average trucks are at work for a very small proportion of their total time, being obliged to remain idle for long periods in goods yards waiting their turn for unloading. Telpherage overcomes this defect by providing a means for unloading and loading trucks at any position in the yards, so as to obviate the necessity for their being taken to the goods station for that purpose. The work which telpherage can readily undertake with advantage may be divided into three classes—viz.: (1) the removal of goods from trucks standing on the rails to warehouses or goods sheds; (2) the transference of goods to wagons or trucks for local distribution; (3) the removal of goods to other rails for reloading in other trucks. In doing this, telpherage replaces to a very large extent the most costly of all labour—viz., manual labour—by an electrical substitute which is at once flexible, easily controlled, and cheap. The telpher line is supported upon posts or bents, or suspended from overhead beams, as circumstances may determine. The locomotive power is furnished by a double telpher, to which is attached an electric hoist. Suspended below the hoist is a carrier which is usually of the platform type, but may be of any convenient form, such, for example, as a sling, bucket, or

Digitized by Google

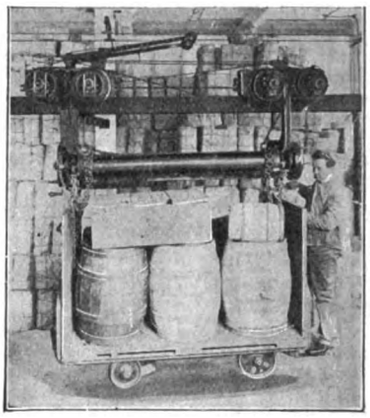
hook. In the accompanying diagram a telpher is shown brought to rest opposite the opening of a goods truck. After the carrier has been loaded it is raised by the hoist and conveyed by the telpher to the warehouse or other destination. The telpherman controls both hoist and telpher by means of switches. Hogsheads may be carried separately or in trains made up of telphers and trailers up to loads of 20,000lb. either automatically or in charge of a telpherman, the hoisting the line run parallel with the walls. In some instances it is desirable for the track to pass through the centre, with branch or gravity line to the centre, or, as is occasionally preferable, to have two side tracks and one or more movable tracks. It is claimed that the transference of goods from railway trucks or warehouses to wagons for local distribution, or from wagons to warehouses, or directly to the trucks, is done much more satisfactorily by a well-designed system of telpherage than by



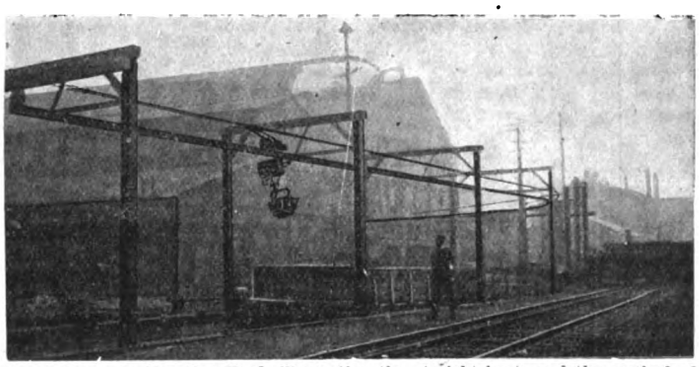
An Electric Hoist attached to a Telpher elevating a loaded truck for transport by the Telpher.



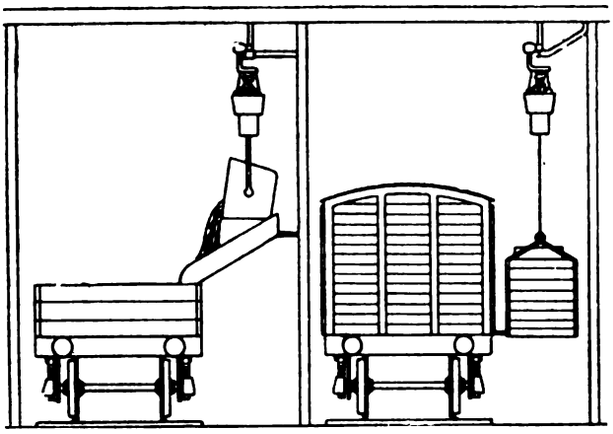
A Load of Miscellaneous Goods approaching a warehouse. The Telpherman's seat is carried by an extension of the Telpher frame.



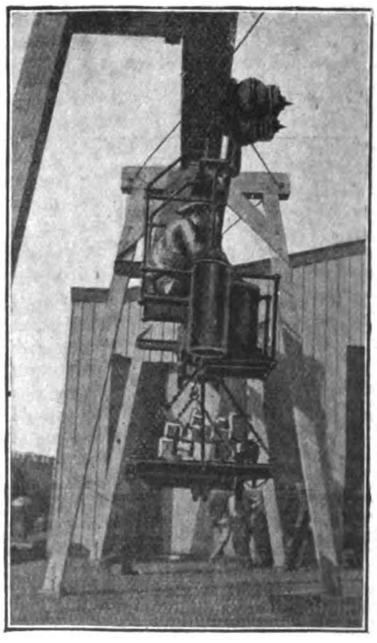
The Telpherman stands at one end of the truck and assists in loading and unloading.



Track Curve in Shunting Yard, illustrating the straight bents and the method of supporting the track and double trolley wire. The line is worked automatically.



An End Elevation of trucks standing on different tracks and served by different Telpher lines.



Load on a trolley in course of being transhipped.

as well as the conveying being done electrically. The construction of the telpher tracks needs little further explanation than the illustrations herewith supply. They are arranged, as shown, in such a manner and at such an elevation as to pass above the wagons and to dispense with the necessity of employing manual labour for the operations of loading and unloading. In interiors it is in most instances desirable to use steel girder rails. The precise form of track, of course, depends greatly upon the local conditions. Usually it is convenient to make any other method, and that the handling of goods to be transhipped is greatly facilitated. The speed of the telpher on straight level stretches of the track may be 800ft. to 1,500ft. per minute, or higher if circumstances permit. Taking into consideration the total work done in a working day, including hoisting, it is found in practice that the average expenditure of power is only about 1 h.p. per ton of average load. Many other advantages are claimed, but for further information we must refer the reader to the source of the above.

ABERDEEN ELECTRICITY UNDERTAKING.

Mr. J. Alex. Bell, the borough electrical engineer, has presented to the Electric Lighting Committee his report on the progress of the above undertaking during the year ending July 31, 1903. He states that with the exception of some lighting switchboard panels, and the erection of the motor-driven pump for the supply of condensing water from the Dee, the whole of the works contemplated in the original contracts are now complete at the Ferryhill station. The committee have now had a full year's working of the whole of the tramways electrically equipped, and that department has consequently become a larger consumer. Two hundred and nine additional consumers have been coupled during the year, making the total number now coupled 1,159. Again, good progress has been made with motor-using consumers; 81 new motors, of an aggregate horse-power of 328, have been connected during the 12 months, 57 of these being hired out from the Corporation. These additions bring the total number of motors on the mains up to 302, representing 1,160 h.p. The units sold for motors during the last four years are as follows: year ending July 31, 1900, 42,326; 1901, 67,244; 1902, 137,486; 1903, 275,038. It will thus be seen that the 1903 and 1902 consumpts have each been 100 per cent. over the consumpt for the previous year. Electrical heating has increased by an equivalent of 387 33-watt lamps; 115 private arc lamps have been added during the year, making the total coupled to date, 350; and 46 public arc lamps have been added, making a total, including the harbour, of 281. There are now coupled to the mains for lighting, heating, cooking, and motors, not including traction, an equivalent of 126,327 33 watt (8-c.p.) lamps. Extension of mains during the year has given an additional frontage of three odd miles of supply. During the year there have been removed from Cotton-street and fitted up at Ferryhill station two 110-kw. and one 200-kw. sets. These three sets were thoroughly overhauled when diamantled. All station plant is in good order, and the capacity of the two stations at present stands as follows: Cotton-street, 760 kw., or 1,270 h.p.; Dee Village, 1,680 kw., or 2,700 kw. A further 700-h.p. set is on order for Ferryhill, which will be delivered in September. The total costs per unit sold, not including interest, depreciation, and sinking fund, come out this year to 1·25d. This is the lowest figure yet reached. Due to the increased tramway consumpt, and to the additional day load obtained from the use of motors, the load factor this year is 17·4 per cent., whereas last year it was only 14·9 per cent. The average price obtained per unit for private supply works out at 3·69d., as against 4·19d. for last year. This is due to the increased number of units sold at 3d. and 1d. for power, and the reduction made in the price per unit to lighting consumers. This latter reduction has affected the revenue to the extent of £1,029. Mr. Bell does not recommend the committee to make any alteration in the present charges for supply, as he thinks they should have another 12 months' working before any further reduction is made.

Below we give an abstract of the accounts for the 12 months ended July 31 last, on which date the capital expenditure stood at £194,079.

Quantity not accounted for			250,157

Number of public lamps, 187 arcs.

ST. PANCRAS ELECTRICITY ACCOUNTS.

The following is the report of Mr. Albert E. Pycraft, chief clerk to the St. Pancras Borough Council, on the working of the electric lighting department during the year ended March 31, 1903, the capital expenditure to that date being £423,500. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are also appended:

Loans have been received during the year amounting to £40,000, making the total loans sanctioned and borrowed £375,620, of which the sum of £33,243. 17s. 5d. has been repaid. The expenditure on account of capital during the year was £45,514. 5s., making a total capital expenditure at March 31, 1903, of £423,500 12s. 8d. The gross revenue for the year amounts to £68,372. 2s. 7d., and the net revenue £32,275. 16s. 11d., which after meeting charges for interest and repayment of loans, etc., leaves a credit balance of £16,818. 0s. 6d. on the year's trading. In making comparison with past years it should be recorded that of this balance a sum of £2,344 is due for accrued interest which has not been taken to account this year in deference to the wishes of the district auditor, who states "that interest only which has become due for payment or has been actually paid should be taken account of." It should also be borne in mind that in the last statement of accounts the income taken to account was not for a full period, by reason of the earlier reading of consumers' meters, and there was a consequent shortage of revenue of about £2,250, to which I drew attention in my last report, whereas the present accounts are for an exact period of 52 weeks' income and expenditure. The increase in revenue from private supply over the previous year is £3,717. 3s., equivalent to 18·5 per cent., which I think may be regarded as satisfactory. The following table shows the progress of the electricity undertaking since the commencement:

Year ending Dec.	No. of consumers.	Current sold to consumers (not including public street-lighting). 3d. per unit. £	s.	d.	4d., 5d., and 6d. per unit. £	s.	d.	No. of lamps, etc., applied for. Incandescent. 16 c.p.	Arc.	Motors.

Stores on hand	1,286	15	11
	£402,484	12	0

Mr. Albert Gay, in his report on the above accounts, says he is disappointed with the result. A net deficit of £1,740 does not appear very encouraging. On going into the figures, however, the reasons for this deficit become obvious. He finds that the average increase in the number of units sold year by year during past years is about 370,000, while the total increase in the year under review as compared with the previous year is only 178,314, which would amount to over £3,000. The reduction in price, and the abolition of meter rents, which came into operation on Jan. 1 last, accounts for a fall in the revenue of £435, while the rates and taxes having been increased from £1,400 to £1,800 is accountable for a further £400. With regard to the cost per unit, he regrets to say that this has increased from 2·71d. to 2·97d., or practically ¼d. per unit, the chief items being repairs, rates and taxes, coal. Unfortunately, the repairs necessary to buildings, machinery, and mains have been exceedingly heavy during the past year, having increased from £1,671 in 1902 to £3,852 last year. This, and the increase in rates and taxes, virtually make up the difference of ¼d. per unit in the costs, a slight increase in the cost of coal accounting for the balance. The above items summarised show results as follows: (1) reduction in price, £435; (2) increase due to enhanced price of coal, £512; (3) increase in rates and taxes, £400; (4) increase in cost of repairs, £2,281—£3,628; and but for these items there would have been a profit of £1,888. Mr. Gay has not the slightest doubt that the accounts for the current year will be far more satisfactory.

LEGAL INTELLIGENCE.

ELECTRIC TRAMWAYS TRUST.

In the Vacation Court on Wednesday Mr. Justice Walton heard the petition of W. Bratby for a winding-up order against the Electric Tramways Trust, Limited.

Mr. Mulligan said the company was registered on Dec. 21, 1900, at which time it had a capital of only £100; but the business had so increased since then that the present authorised capital was £60,000. Of this, there had been issued £2,167. The petitioner was a creditor for £516, and his debt was admitted. It was due upon bills accepted by the company, and which matured in July last. The company had passed extraordinary resolutions to wind up voluntarily.

Mr. Bramwell Davis, for the company, said there were no assets, not even enough to pay the costs of the petition. The British Motor Traction Company and the British Electric Street Tramways Company, which held shares in the company, were both in liquidation.

His Lordship granted a supervision order for winding up, with liberty to apply in chambers for an additional liquidator.

FERRANTI LIMITED.

Before Mr. Justice Walton in the Vacation Court on Wednesday, **Mr. Bramwell Davis, K.C.**, said that in the matter of Ferranti Limited—Poole *v.* Stirling—it was a case in which his Lordship had already appointed the *ex parte*, a receiver and manager, with leave to borrow £2,000. He (counsel) appeared for one of the trustees for the debenture holders (Mr. William Jones), and also for Parr's Bank, who hold second debentures for £30,000, and who were not parties to the action at that moment. His application was that Mr. Whittaker should be joined with Mr. Tate as receiver and manager of the company's property and business. Mr. Jones, in his affidavit, set out that this was a very large electric business, carried on at Manchester, and it was absolutely necessary for someone on the spot, like Mr. Whittaker, to supervise and carry on the business.

Mr. Justice Walton made the appointment as now asked, with leave to borrow £20,000, less the sum of £2,000 already borrowed, and with leave to apply £2,000 to meet the current weekly wages bill.

COMPANIES' MEETINGS AND REPORTS.

ELECTRIC RAILWAY AND TRAMWAY CARRIAGE WORKS.

The report of the directors to be submitted to the ordinary general meeting of the shareholders on 24th inst. states that the works have been efficiently maintained during the year as regards buildings and machinery, the cost of which has been charged against revenue. After paying debenture interest amounting to £2,500, and charging £5,096. 3s. 9d. for depreciation, the profit for the year is £16,594. 14s. 11d., to which must be added £2,832. 3s. 8d. brought from last year, making a total of £19,426. 18s. 7d. The directors recommend that this amount be dealt with as follows: to carry to general reserve fund, £2,000; to pay a dividend of 8 per cent., less income tax, for the year ending June 30, 1903, £12,000; to carry forward to next year, £5,426. 18s. 7d.—total, £19,426. 18s. 7d.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Macao.—The Colonial Office at Lisbon invite tenders for the electric lighting of Macao. Tenders by Oct. 21.

Lisbon.—The Public Works Department require tenders for the public electric lighting of Macao. Tenders by Oct. 21.

Bucharest.—The Government Railways require tenders for the installation of electric lighting and plant for their workshops. Tenders by Oct. 10.

Paris.—The Post and Telegraph Department, Rue de Grenelles 103, invite tenders for (1) 190,000 ko. bronze or copper wire and 94,000 joints, and (2) 12 kilometre submarine telegraph cable.

Transvaal Colony.—The Chairman of the Tender Board, Pretoria, requires tenders for installing and working the electric lighting of Potchefstrom for about five years. Tenders by Oct. 30.

Kirkcaldy.—The Corporation invite tenders for supply of all fittings for installing the electric light into the memorial halls in Bennochy-road. Tenders by Sept. 12. See advertisement.

Croydon.—The Council invite tenders (1) for the building works and (2) for the smith and ironfounders' work in connection with the extension of the electricity works, Factory-lane, Croydon. Tenders by Sept. 14. See advertisement.

Dublin.—The Port and Docks Board invite tenders for the supply of a 100-ton electric crane. Specification can be obtained at the office of the engineer to the Board, Mr. John P. Griffith, M.I.C.E., Eastwall, Dublin. Tenders by Oct. 5.

London, E.—The Whitechapel Guardians invite tenders for electric lighting of a portion of the infirmary. Specifications, etc., may be obtained from Mr. F. J. Tootell, clerk, Union Offices, 74, Vallance-road, N.E. Tenders by 12th inst.

London, E.—The Whitechapel Guardians invite tenders for electric lighting of a portion of the infirmary. Specifications, etc., from Mr. F. J. Tootell, clerk, Union Offices, 74, Vallance-road, N.E. Tenders must be sent in by Sept. 12.

Huddersfield.—The Corporation invite tenders for the supply and delivery of about 30 tons of steel tramway rails (girder section), with fishplates, tierods, bolts, trolley poles, bracket arms, overhead-line material, &c. Tenders by Sept. 16. See advertisement.

Shanghai.—The French Colony propose to instal motor-propelled tramways. Tenders may be sent by Oct. 31, 1903, to Secrétariat de la Municipalité Française de Shanghai. Particulars may be obtained from l'Office National du Commerce Extérieur, Rue Feydeau, 3, Paris.

Rotherham.—The Tramways Committee invite tenders for supply of an electric watering car and track sweeper. Full particulars may be obtained from Mr. Grant, Tram Depot, Rotherham. Tenders to Mr. H. Hampton Copnall, town clerk, Town Hall, Rotherham, by 18th inst.

Brussels.—The Post and Telegraph Department require tenders for 111,500 ko. galvanised iron wire, 5,100 ko. wire cable, 1,875 ko. copper wire, 532,900m. copper wire, 153,650 insulators, etc. Specification No. 200 at above. Tenders by 11 a.m. on Sept. 16 at the Bourse.

Rochdale.—The Guardians invite tenders for certain new underground cables and switchboard alterations and additions required at the workhouse, Dearnley. Specifications, etc., may be obtained from Messrs. Shepherd and Watney, Greek-street-chambers, Leeds. Tenders by 26th inst.

Russia.—The Russian Minister of the Interior has sanctioned a plan for the reconstruction of three lines of municipal tramways—namely, those in Newsky, Sadovaia, and Wassiliostrow districts. Each car is to provide for two classes of travellers, and will accommodate 52 persons.

Utrecht.—The Town Council will receive tenders for supply and erection of a central electric establishment for lighting, power supply, and working tramways. Contract, conditions, etc., to be obtained at the "Gemeente Secretaire" of Utrecht, on payment of 5fl. (8s. 4d.). Tenders by Oct. 1.

Southend-on-Sea.—The Corporation invite tenders for steam dynamo, boiler, and condenser. Specification, etc., may be obtained from Mr. W. E. J. Heenan, M.I.E.E., borough electrical engineer and general manager, Southend-on-Sea. Tenders by noon on Sept. 14. See advertisement.

Brighton.—The Town Council invite tenders for the (1) supply of steel girder tramrails, fishplates, etc.; (2) tramcars; (3) points and crossings and other fittings. Specifications, etc., may be obtained from Mr. Francis J. Tillstone, town clerk, Town Hall, Brighton. Tenders by 10.30 a.m. on Oct. 5.

Leeds.—Tenders are invited for concrete engine and dynamo foundations in Whitehall-road, for the Electric Lighting Committee. Plans, etc., may be obtained at the office of Messrs. Milnes and France, 99, Swan-arcade, Bradford. Tenders by 15th inst. to Mr. W. J. Jeeves, town clerk, Leeds.

West Ham.—The Guardians invite tenders for the supply of various articles to the workhouse infirmary and schools for 12 months from Sept. 29, including asbestos goods, electrical fittings, engineers' sundries, etc. Tenders to the Clerk's Office, Union Workhouse, Leytonstone, N.E., by 10 a.m. on Sept. 16.

Madrid.—The Telegraph Section of Posts and Telegraph Department, Madrid, invite tenders for telegraph and telephone apparatus (Morse receivers, Morse manipulators, switches, Ericcson instruments, etc.) of a total estimated value of about £2,190. Tenders by 19th inst. A provisional deposit of 5 per cent. is required.

Glasgow.—The Corporation invite tenders for the supply and erection of electric cables, main switches, distributing boxes, and other accessories required for Baltic-street baths and wash-houses. Specifications, etc., may be obtained from Mr. J. Lindsay, clerk, City Chambers, Glasgow. Tenders by 10 a.m. on 16th inst.

Johannesburg.—The Municipality require tenders for gas generating plant or for steam generating plant and for gas motors or steam motors, with electric generators and accessories. Particulars may be obtained from the Town Clerk, Johannesburg, or from Messrs. Mordey and Dawbarn, 82, Victoria-street. Tenders by Oct. 19.

Launceston (Tasmania).—The Mayor and Aldermen invite tenders for the supply of 500 or more electric meters. Particulars may be obtained on application to Mr. William Corin, city electrical engineer, Launceston, Tasmania, or to Messrs. John Terry and Co., 7, Great Winchester-street, London, E.C. Tenders by Sept. 28.

Cienfuegos (Cuba).—The Municipal Authorities require tenders for the installation and working of electric lighting. They will pay an annual subsidy of 24,000 piastres for 150 arc lamps of 1,500 c.p. each and 350 incandescent lamps of 50 to 100 c.p. each for street lighting, and 16 to 25 lamps in public buildings. Tenders by 1 p.m. on Sept. 28.

Edinburgh.—The Council invite tenders for the following works in connection with the proposed extension of Macdonald-road electric power station: (1) building works, including excavator, mason, brick, joiner, slater, plasterer, plumber, and glazier's work; and (2) smith and ironfounder's work. Tenders must be sent to Mr. R. Morham, city architect, by 10 a.m. on Sept. 14.

London, S.E.—The London County Council invite tenders for the supply, delivery, and erection in the electricity generating station to be established by the Council at Greenwich of four 5,000-h.p. vertical-horizontal steam-engines, each suitable for driving a three-phase generator. Particulars, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 6.

Bradford.—The Corporation invite tenders for the construction of about 13 miles of light railways and tramways in connection with the Angram storage reservoir works. Plans may be seen and specifications, etc., obtained at the office of Mr. James Watson, M.I.C.E., waterworks engineer, Town Hall, Bradford. Tenders to Mr. Frederick Stevens, town clerk, Town Hall, Bradford, by 10 a.m. on Oct. 1.

Birmingham.—The Tramways Committee require the names of contractors who are desirous of tendering for the supply and delivery of materials and fittings as follows: (Section A) manganese steel points and crossings; (B) tapered steel side poles and bracket arms; (C) suspension ears, pull-offs, section insulators, and other overhead materials; (D) hard-drawn copper trolley wire and stranded steel span wire. Mr. John Price, city engineer, Council House, Birmingham.

Stoke-upon-Trent.—The Corporation invite tenders for the supply and erection of the following plant in connection with the proposed electricity and destructor works: (Contract 10, Section A) pipework; (B) non-conducting covering; (C) water-softening plant. Persons are at liberty to tender for any single section. Specifications, etc., can be obtained from Mr. P. J. S. Tiddeman, Field-place, Stoke-upon-Trent. Tenders to Mr. Jno. B. Ashwell, town clerk, Town Hall, Stoke-upon-Trent, by 5 p.m. on Sept. 11.

Bermondsey.—The Borough Council invite tenders for (Contract No. 12) the construction, supply, and erection of two dust-destructor cells, with furnaces, flues, etc., and storage bins, one water-tube boiler and brickwork settings, one water storage tank, with supports for same, and extensions to the steam, feed, and exhaust piping system; (13) the construction, supply, and erection of two 300 kw. steam generators, two 20-kw. feeder boosters, one 15 kw. motor-balancer, and sundry switchgear and connecting cables. Specifications can be obtained from Mr. Fredk. Ryall, town clerk, and may also be inspected (but not obtained) at the offices of the engineers, Messrs. Kincaid, Waller, Manville, and Dawson, 29, Great George-street, Westminster. Tenders by Sept. 21. See advertisement.

London, E.C.—Tenders will be received until noon on Sept. 28 (a for the supply of Swedish, Norwegian, or Finland red fir telegraph poles, to be delivered in London, at Northumberland Dock (River Tyne), West Hartlepool, Hull, or Grimsby, at Leven, Fifeshire, and at Swansea, Cardiff, or Newport; and (b) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot, as may be directed. The poles to be felled during the winter of 1903-4, and to be delivered during the following summer at the port at which the creosoting is to be performed. Butt sections, 2in. thick, stamped with the shipper's mark, from not less than three poles, to show the quality of timber offered, must precede or accompany the tender of any person who has not already supplied the Postmaster-General with poles. Forms of tender may be obtained from Mr. S. C. Hoolley, controller of stores, Stores Department, 17-19, Bedford-street, London, W.C.

RESULTS OF TENDERS.

Preston (Lancs.).—The Town Council have accepted the tender of T. B. Garnett, Preston, at £11,000, for the construction of a tramway car-shed.

Colchester.—The Electric Light Committee have accepted Messrs. Statter's tender to supply certain additions to the traction switchboard at a cost of £99.

Pietermaritzburg.—The tender of Messrs. Strong and Moore has been accepted for the laying down of the permanent way for the electric tramway system at £16,856.

West Ham.—The Town Council have accepted the tender of the British Thomson-Houston Company, Limited, Rugby, at £2,183, for traction switchboard, etc., complete with electrical equipment.

Johannesburg. — The Hadfield Steelfoundry Company have secured the contract for points and crossings for the tramways at £5,355 8s. 7d., f.o.b. British port; whilst Messrs. Askham Bros. and Wilson (p.p. Edgar Allen and Co., Limited, Sheffield), through the Brush Electrical Engineering Company, are to supply the tiebars, sole joists, bolts, etc., at £3,333, f.o.b. The bulk of the contract was secured by the Brush Company, who for grooved rails represented the interests of the Société Anonyme d'Ougrée, Belgium.

London.—The Metropolitan Asylums Board have received the following tenders for electric lighting of receiving home for children:

Buchanan and Curwen, 64, Victoria - street, S.W. (accepted)	£398	0	0
Wenham and Waters, Limited, Paragon Works, Croydon	407	0	0
V. G. Middleton, Broadway-chambers, Westminster, S.W.	443	0	0
Eastlakes, Limited, 4 and 5A, Cowley-street, Westminster, S.W.	450	0	0
Drake and Gorham, 66, Victoria-street, S.W.	496	0	0
Hayward-Tyler and Co., 90 and 92, Whitecross-street, E.C.	503	16	6

London, W.—The Chiswick Urban District Council have received the following tenders for gas-driven sewage pumping plant, compressors, and electric lighting sets:—

Bilbie, Hobson, and Co.	£6,500	0	0
Campbell Gas-Engine Company, Limited	3,513	7	6
Crossley Bros., Limited	3,304	0	0
Drysdale and Co.	1,930	0	0
J. and H. Gwynne, Limited	5,305	0	0
Gwynne and Co.	3,527	0	0
Pollock, Whyte, and Waddel	3,202	0	0
Sir Hiram Maxim Electrical Engineering Company (accepted)	3,197	2	0
D. Stewart and Co. (1902), Limited	2,772	0	0
Tangyes, Limited	4,470	0	0
J. Wolstenholme and Son	3,562	10	0

BUSINESS NOTES.

LIGHTING AND GENERAL.

Crewe.—Arc lamps are to be placed in the principal streets.

Nelson.—The Town Council have decided upon cable extensions at a cost of £250.

Halifax.—Sanction has been obtained for a loan of £19,000 for electric supply.

Accrington.—The borough accountant has been authorised to raise £6,890 for electric lighting.

Holland.—It is proposed to expend £4,000 in installing the electric light at the County Council asylum.

Wednesbury.—The Town Council have been authorised to raise a loan of £11,000 for electric lighting purposes.

Farnham.—The local gas company have offered to take over the order obtained by the Urban District Council.

Sheffield.—The Council propose to extend the electric lighting mains in various directions at a cost of £1,303.

Yarmouth.—The Guardians have decided that the electric light be installed at the workhouse at a cost of £19. 10s.

Warrington.—The Town Council have received sanction to the borrowing of £18,600 for the purpose of electric lighting.

Consett.—The Urban District Council have referred to a committee the question of lighting the district by gas or electricity.

Batley.—The Town Council intend to apply for sanction to borrow an additional £5,000 for the extension of the electric cable.

Lytham.—The Council are collecting information as to the cost of producing electric current by gas power as compared with steam.

Llandilo.—An enquiry is to be held into the Urban District Council's application for power to borrow £1,300 for additional plant.

Morpeth.—Plans for the erection of a power station on the Low Stanners for the Northern Electric Supply Company have been passed by the Town Council.

Bexley.—The District Council intend to apply for sanction to borrow £1,760 for purposes of public and private electric lighting in the East Wickham ward.

Penmaenmawr.—The District Council are conferring with Messrs. Lacey and Sillar, of Manchester, consulting engineers, *re* a report upon an electrical installation.

Hythe.—The Folkestone Electric Lighting Company have now taken over the whole of the public lighting of the town. It is proposed to provide a number of extra power lamps.

Dumbarton.—The Clyde Valley Electric Power Company intend to apply to the Board of Trade for an electric lighting order for parts of the parishes of Bonhill, Cardross, and Dumbarton.

Blaydon.—The Urban District Council are conferring with the Priestman Power Company, who are desirous of taking over the Council's responsibilities under their provisional order.

Mansfield Woodhouse.—Application is to be made by the Council for a provisional order to authorise the supply of electricity for public and private purposes within the urban authority's district.

Newport.—The Electricity Committee have decided that it would be contrary to the policy of the Council to accept the gas company's offer, and recommend that the scheme for arc lighting be proceeded with.

Personal.—The following appointments have been made in connection with the Bexley Council's electricity undertaking: senior charge engineer, Mr. H. Knorr; junior charge engineer, Mr. J. D. Laws.

Perth.—The Electric Lighting Committee are considering a request for a service in Kinnoull district. The Electric Committee propose to apply for powers in the new omnibus Bill to let out small motors on hire.

Brighton.—It has been resolved that as an experiment for one year the charge for the supply of electricity to premises controlled by a time switch be 1d. per unit from 8 o'clock, instead of from 10 o'clock in the evening.

Portsmouth.—The last electric light accounts show a net profit of £3,000, which will help to swell the reserve fund. The profit on the committee's operations during the year was £14,079, of which £11,079 went for interest on loans, etc.

Gloucester.—An enquiry has been held into an application of the Corporation to borrow £25,000 for purposes of their electricity undertaking, including the provision of the additional plant required for supplying power for the proposed light railway.

Bann Motor Company, Limited.—This company has been registered with a capital of £12,500, £2,500 being preference shares, for the purpose of dealing in all sorts of steam, electric, or other engines and motors. Registered office: Portadown, co. Armagh.

Yardley.—The Rural District Council have appointed a special committee for the purpose of consulting the British Electric Traction Company as to the lighting of the main roads in the parish of Yardley with electric light, and ascertaining the cost of same.

Eccles.—The Council have reduced the charge for energy supplied for the borough distributing mains for motor or power purposes. During the past three months the apparent loss has only been £229, whilst for the same period in 1902 it was £372, and in 1901 £515.

Ripon.—The Council will oppose the Empire Electric Light and Power Company, Romford, who intend to apply for an electric lighting order for the city in the next session of Parliament. The Council will probably apply for an extension of their electric lighting order.

Colchester.—At the last Council meeting the report of the Electric Light and Power Committee, which included a recommendation that certain tenders amounting to £99 be accepted, subject to the Local Government Board's sanction to a loan of £7,000 being obtained, was adopted.

Darlington.—The minutes of the Electric Lighting and Tramways Committee submitted to the last Town Council meeting showed a considerable increase in the number of units generated in the electricity department, and applications had also been received from 30 intending consumers.

Bognor.—The Urban District Council have adopted the scheme of the Industrial Engineering Company for installing electric plant in the town subject to an agreement and to the Board of Trade's approval of the same, and to the Local Goverment Board agreeing to the Council leasing the land.

Kirkcaldy.—The Tramway and Electric Lighting Committee have decided to lay electric lighting mains throughout Commercial-street, a sufficient number of connections having been guaranteed to warrant the committee undertaking the extension. The street is also to be lit with arc lamps.

Leicester.—Tenders will be advertised for plant for the electric lighting of the North Evington Hospital. The cost will be approximately £7,000. The Corporation will do the wiring at net cost, and Mr. Colson, the borough electrical engineer, has promised to superintend the work.

Glasgow.—The Electricity Committee have resolved to recommend that the department be authorised to supply electric motors on hire. A small motor, it is stated, may be let for about £3 per annum, while a motor of 25 h.p., which would cost £250 to purchase, may be rented for about £20 per annum.

Swansea.—The demand for electricity has increased by 94 per cent., 139,000 units being sold in the quarter ending June 30 last, as compared with 71,000 units during the corresponding period of last year. With regard to the proposed electric lighting of Morristown a canvass of the district affected is to be made.

Loughborough.—Last month the borough surveyor was given permission to act jointly with Mr. C. H. Gadsby, the electrical engineer, in preparing the architectural work in connection with the electricity power station. The resolution granting such permission was, however, rescinded at the last Town Council meeting.

St. Annes.—The electrical engineer in his last report states that the number of units sold to July 31 was 104,489, against 27,489 in 1902; the maximum load for lighting was 111 kw., against 93 kw., and for traction 220 kw.; the number of consumers is 194, against 113. A number of new electric lighting mains are to be laid.

Digitized by Google

Whitby.—The Urban District Council are raising £2,500 for the extension of the cable in Fishburn Park and for a mechanical stoker. The Finance Committee in their last report state that the receipts from private consumers of the Council's electric light would amount to £500, as compared with £250 for the preceding half-year.

Automatic Fire Alarms.—Honorariums of £50, £30, and £20 are respectively offered for (1) the best form of and quickest operating thermostat for closed circuits; (2) a means of "testing back" from a fire station to a factory to distinguish from or ascertain if the fall of a drop indicator is caused by heat, or by short-circuit, or tampering, etc. Further particulars appear in our advertisement columns.

Automatic Signalling.—In consequence of the heavy rains of last week, the electrified portion of the District Railway was flooded in two places. The water partially submerged the running and negative rails. We are informed that, in spite of this, the track circuits of the Westinghouse automatic signal, with which this line is equipped, were not in any way affected, and the trains were signalled without a hitch.

Clydebank.—The poll to decide whether the burgh should or should not carry out its own electric light provisional order, combined with the building of a dust destructor, resulted as follows: Number of papers issued, 3,183; returned, 1,459; 1,104 against, and 355 for. This means that the order will be acquired by the Clyde Valley Electric Power Company, who are laying down a considerable amount of plant at Yoker.

West Hartlepool.—The following scale of charges for current for motors has been adopted: for less than 150 units per horse-power installed per quarter, at 2d. per unit; 151 units, and not exceeding 200 installed per quarter, at 1¾d. per unit; 201 units, and not exceeding 250 installed per quarter, at 1⅝d. per unit; 251 units, and not exceeding 300 installed per quarter, at 1½d. per unit; 301 and above installed per quarter, at 1¼d. per unit.

Gainsborough.—The question of procuring an electric lighting order was considered at the Council meeting, and it was agreed to make an application for a provisional order to produce and supply electricity within the urban area. The suggested streets upon which lines should be laid were Church-street (portion), Market-place, Silver-street, Bridge-street (portion), Market-street, Beaumont-street, and Trinity-street. The estimated cost is £12,000.

Lowestoft.—The electrical engineer in his last report states that there have been five new consumers connected up to the mains during the month, which, with extra lamps, represents 150 8-c.p. lamps added during the month. There are now 418 consumers, representing 23,347 8-c.p. lamps connected to the mains. The engineer has been instructed to communicate with free wiring companies and obtain tenders and report thereon to a future meeting.

Salford.—Application is to be made for permission to charge the sum of £34,443. 16s. 9d. over expended on the main building of the electricity works, machinery and plant, and mains, etc., against the borrowing power of £43,282 granted for feeding cables, section boxes, and electrical equipment for the tramways, but not used; and if such permission be declined, to apply for additional sanction to borrow the sum of £34,444, or such further sum as may be found necessary to cover the excess expenditure.

Dundee.—An immediate start is to be made by the North British Railway Company with the installation of electric lighting at the platforms and buildings connected with Tay Bridge Station, the goods yard, and the lyes, where extensive shunting operations are regularly carried on. The supply, it is understood, will be drawn from the Corporation works. The necessary plant will be furnished by the North British depôt, and the work of installation will devolve upon the engineers in the company's employ

New Issue.—The Weston-super-Mare and District Supply are issuing £35,000 4½ per cent. first mortgage debenture stock and 34,930 6 per cent. cumulative preference shares of £1 each. This company was formed in 1899 to take over the Weston-super-Mare Electric Lighting Order, 1891, granted to the Urban District Council of Weston-super-Mare. The company have since obtained the Weston-super-Mare Tramways Orders, 1900 and 1901, authorising the construction of tramways about four miles in length, of which nearly three miles have been constructed. The generating station was opened in May, 1901, and the tramways in May, 1902.

The Electrical Rugby Football Championship.—The long-deferred match between Glover's and Chloride was played off on Wednesday on the Broughton Rangers' ground at Manchester, and resulted in the "Cables" boosting the "Accumulators" by two tries to one. The game was chiefly remarkable for the number of personal injuries sustained, the losers having one man's shoulder broken within the first 10 minutes. The tries for the winners were scored by Horton and Brady, and Causer scored the losers' point. Both works closed early for the game, and despite the bad weather a large number of electrical works were represented among the spectators.

Bury.—The engineer (Mr. L. P. Greig) in his last report states that the new engine and dynamo have been erected and grouted down upon the foundations, and as soon as the closing pieces of the piping have been received, the engine and dynamo could be run on the load, which was increasing rapidly. The condensing plant had been running, and had effectually done away with the boom of the exhaust steam. It was suggested that the committee hold their next meeting at the works in order to inspect the whole of the new plant while in operation. The committee have resolved to place an additional lamp in Cotton-lane, and also to hold the next meeting of the committee at the works. The remuneration of the two assistant engineers has been increased by 5s. per week each.

Teddington.—The Twickenham and Teddington Electric Supply Company, who have leased the order for the supply of electric light obtained by the Teddington District Council, commenced the laying of the cable on Monday from Normansfield, Kingston-road, towards St. Albans. The company have deposited plans for laying cable in nearly the whole of the roads contained in the specified area. The company have already recouped the District Council the cost of obtaining the order, which amounted to upwards of £300, and besides undertaking to pay a rental of £100 a year, they have granted favourable terms for street-lighting. Purchase terms have also been arranged under which, we understand, the District Council may acquire the undertaking at the end of 7, 14, or 21 years, if they think fit.

Mountain Ash.—The Ocean Coal Company have erected at their Treharris Colliery an electric pump, displacing the old Cornish pump formerly used at the colliery, and relieving the use of several boilers, which undoubtedly will repay the owners for their enterprising outlay. The pump was supplied by Messrs. Ernest Scott and Mountain, Limited, Newcastle-on-Tyne, who were represented in the erection of same by Mr. Scott, agent, of Cardiff, the firm's local representative; and Mr. G. Gillender, the erector. The plant consists of a horizontal long-stroke compound 300-h.p. engine; a 170-kw. continuous-current dynamo, driven by ropes from the engine; main switchboard, with instruments and switches, shaft, and underground cable; 170-h.p. electric motor for driving the pump; and set of Scott and Mountain's special high-lift, three-throw ram pumps to deliver 250 gallons per minute against 1,500ft. head. The old pump will be kept in reserve in case of emergency.

Strike.—The Central News says the men employed by the Westinghouse Electric Company on the new electric generating station at Neasden, now in course of construction for the Metropolitan Railway, went out on strike in a bunch on Monday morning. The Westinghouse Company state that the men appealed for higher wages, and this being refused, all the employés, who number over 300, struck work. According to statements made by the men, it appears that there had been considerable friction between Mr. Huntingdon, the manager of the Westinghouse Company, and the workmen. The men allege that since the commencement of the work their manager has used the American system of driving. Their special grievance is, they aver, that unless they are at their places on the scaffold, etc., and start work the moment the hooter sounds, continuing to work right up to the last minute, they are dismissed. All the original staff of men are still out on strike, but the company have since filled their places by taking on an entirely fresh staff.

Cheltenham.—At the last monthly meeting of the Town Council the position of the electric undertaking was discussed, and it was said that in eight years there had been an absolute loss of £17,000. Alderman Norman, chairman of the Lighting Committee, replied that this sum of £17,000 had never come out of the ratepayers' pockets. It stood to a suspense account, and was balanced by £10,010 in the sinking fund and another £24,425 now awaiting investment. He went into an exhaustive explanation of the causes of the accumulation of the so-called "losses," one of which was the increased interest now payable on money borrowed from the bank compared with that paid on loans when the installation was put in, and showed that during the eight years the undertaking had made a profit of £21,038 over and above its working expenses. Had the concern been in the hands of a private company it would, on this basis, have earned a dividend of 4·88 or nearly 5 per cent. He repudiated the charge of mismanagement, and showed that the Cheltenham station cost in capital expenditure £3 per kilowatt less than the average throughout the country, and that its working expenses were only 1·57d. per unit, as compared with 2·10d. elsewhere.

Paper Mills.—The British Westinghouse Electric and Manufacturing Company are installing plant for the electrical driving of the mills of the Donside Paper Company, Aberdeen. The plant will include one Babcock and Wilcox boiler, fitted with chain-grate stoker, superheater, and economiser, which will supply steam at 200lb. steam pressure to a Browett and Lindley triple-expansion engine. This will in turn drive a 375-kw. Westinghouse double-current generator, giving on the alternate-current side three-phase current at 220 volts, 25 periods, and on the direct-current side current at 125 volts. Continuous current will be used for the variable-speed motors, of which about 75 kw. will be installed. All other motors will be of the Westinghouse polyphase induction type. These will include five 50-h.p. motors for the beaters and breakers, one 35-h.p. for driving a Marshall breaker, and three smaller motors driving the starching plant and edge runners. One 75-h.p. variable-speed motor will drive the dry end of the paper-making machine and a 30-h.p. motor the wet end. In addition to these, all the pumps will be electrically driven, as will also the finishing house, ink grinders, and so forth. It is anticipated that the electric driving will effect a very large economy in coal consumption, and a further consideration, which has no doubt proved of much importance in this case, is the flexibility of electricity as compared with mechanical driving in view of certain extensions contemplated in these mills.

TRACTION.

Liverpool.—The Board of Trade have sanctioned increased speeds on several of the tram routes.

Swansea.—Plans for the proposed tramway extensions have been approved and tenders will shortly be invited.

Hampton Wick.—Preparations are being made for the early construction of the proposed tramway through this district.

Perth.—At a meeting of the Town Council held on Monday it was agreed to borrow £17,000, the purchase price of the tramway company's undertaking.

Digitized by Google

Mont Blanc.—It is proposed to construct an electric railway up Mont Blanc, utilising water power in the generation of the electricity.

Accrington.—The Town Council and the Tramways Comwany are discussing the question of the conversion of the local tramway system from steam to electricity.

Stockton.—The Rural District Council have decided to support any movement in favour of inducing the tramways company to extend their system to Haverton Hill.

Bury.—With reference to the question of the tramway purchase, Sir Frederick Bramwell will next week inspect the lines in the district on behalf of the Board of Trade.

Soothill Upper.—The Tramways Committee have arranged an interview with Mr. Paris, of the tramways company, with reference to the suggested Dewsbury Moor extension.

Leeds.—The system of ½d. fares on the tramways has been considerably extended. A new route from Malvern-road, Beeston Hill, to Kirkstall-road was opened for traffic on Monday.

Londonderry.—There is a proposal for the construction of an electric railway from Londonderry to Moville, and formal application is to be made to the Lord-Lieutenant in Council for an order.

Nottingham.—The present state of the money market and of the borough finances have been accepted by the Tramways Committee as reasons for delaying the construction of the London-road tramway for a time.

Chesterfield.—The Town Council on Tuesday adopted a scheme of tramways prepared by Mr. Goodyer, an expert, in conjunction with the resident engineer, Mr. Acland, for the borough, the estimated cost being £87,000.

Burnley.—At the last meeting of the Town Council the new by-laws permitting overcrowding in the trams to the extent of 10 persons inside were opposed, but after further discussion the by-laws were approved.

Woking.—The proposals for a system of light railways in Woking and Bagshot districts are gaining favourable reception locally, and the scheme is being pushed on energetically, with a view to an early application for an order.

Birkenhead.—The Corporation tramways annual report shows a gross profit of £22,509 on a car mileage of 1,279,037, and a net profit, after payment of interest and sinking fund, of £3,598, which has been placed to the renewals fund.

Colchester.—The Town Council have resolved that the Board of Trade be asked to sanction the inclusion of £887, half the cost of widening Middleborough and North Station road, in the loan of £61,164 sanctioned by the Board for tramway purposes

Rochdale.—The Town Council have adopted a resolution to give the requisite notice to the tramway company to purchase that part of the undertaking constructed in Rochdale borough under the Manchester, Bury, and Rochdale Tramways Extension Order of 1882.

Cardiff.—At the meeting of the Town Council on Monday it will be moved that the Tramways Committee be instructed to proceed with the work of constructing a new line from Talygarn-street, Cathays, along Crwys-road, so as to make a connection with the Castle-road route.

Nelson.—At the last meeting of the Town Council it was resolved that application be made to the Local Government Board for sanction to the borrowing of £25,000 for the purposes of the electricity department. The money is required for extension of plant in connection with the light railways.

Leicester Light Railways.—The Light Railway Commissioners have submitted to the Board of Trade for confirmation the order made by them for the construction of light railways in the borough of Leicester and in the rural districts of Barrow-upon-Soar, and of Market Bosworth in the county of Leicestershire.

Burton.—The Highways Committee having charge of the tramways, recommend the Council to grant workmen's tickets at the rate of 12 for 10d. for use on the cars any route, any distance, between 5.30 a.m. and 7.30 a.m. and between 5 p.m. and 6.30 p.m.; also that children under 12 ride on any single route for 1d.

Railway Motors.—A correspondent calls our attention to a printer's error in our "note" under this heading in last week's issue. It was stated that the North-Eastern Railway has commenced its service of motor 'buses in North Holderness, between Beverley and "Belford." The last-named place should have read "Beeford."

Darlington.—The question of the price to be charged for electrical energy to be supplied for the light railways has been referred to a sub-committee for consideration and report. Prof. Kennedy has been invited by the Tramways Committee to inspect the new permanent way which has been laid down in connection with the electric traction scheme.

Glasgow.—A special committee has been appointed to consider the report of Mr. Young, already published, and to report on the whole question of ½d. tramway fares. A proposal will be brought before the Town Council in favour of adopting a larger size of car. The whole question of the future extension of the tramways has been remitted to a sub-committee.

Darwen.—The Corporation tramways department has commenced a new express parcel delivery service, under which parcels will be delivered and carried over several sections. The committee have also started a new scale of parcel rates, including delivery within half a mile of the tram route; also for delivery within Darwen or Blackburn within one mile of the tram route.

Leigh.—The recommendation of the Tramways Committee, that a sub-committee be appointed to report as to whether the tramways within the borough should be constructed with a view to their being worked by the Corporation or leased to a company, was approved at the last meeting of the Town Council, and the sub-committee were authorised to engage expert assistance.

Herefordshire.—At the last meeting of the Ross Rural District Council the scheme for providing the county of Hereford with a system of light railways was discussed, and a resolution passed asking each council affected by the proposal to appoint three delegates to attend a meeting which the chairman of the County Council (or, failing him, the Mayor of Hereford), should be requested to convene to discuss the question.

Durban.—The Corporation have completed their "outer" circle of tramways, and passengers are now able to make a complete circuit of the town without disembarking. Since the installation of electric trams, some 15 months ago, the old horse cars have almost fallen into desuetude, and at the present time only about half a-dozen are running. In a few months the horse trams will be entirely swept away and replaced by electric cars.

"Tube" Breakdown.—Much inconvenience was caused about seven o'clock on Tuesday evening by an obstruction on the Twopenny Tube. A train was running between the Bank and the Post Office Station when a coach left the metals, bringing the whole train to an abrupt standstill. All the passengers reached the Bank Station without mishap of any kind. Traffic was considerably delayed between the Bank and British Museum Stations.

Lowestoft.—The general manager reports as follows: total receipts for the six weeks ending Sept. 1 amount to £2,294. 13s. 1d.; passengers carried, 494,623; miles run, 32,958; average receipts per day, £54. 12s. 7d.; average receipts per car per day, £5. 2s. 7d.; average miles run per car per day, 73 56; average receipts per car per mile, 16·70d. Four new cars are being obtained by the committee, and the car-shed is to be extended by one bay in consequence.

Newcastle.—At a meeting of the Finance Committee of the Corporation last Thursday, the 3rd inst., it was reported that the total amount paid for tramway construction was £962,000. Of this sum, £87,000 had been borrowed. Application was being made to the Local Government Board for power to borrow an additional £128,000 for tramway purposes and street improvements. The town clerk was instructed to press this matter forward, that the amount required may be obtained.

Batley.—In reply to questions at the last meeting of the Town Council, the Mayor said he could give no information as to when the trams would be running. No communication had been received from the British Electric Traction Company, who alleged that their cars were not adapted for the Batley lines. There was not sufficient bite, it was said, on the wheels, and if the company ran their cars some accident might occur. Everything was ready so far as they (the Corporation) were concerned.

Eastbourne.—After hearing a deputation urging the introduction of electric trams in the town, the Town Council at their last meeting rejected by 17 votes to 9 a proposal to promote a Tramways Bill in the next session of Parliament. A resolution in favour of calling a town's meeting was also thrown out. We understand that the reason for the Council's attitude in this matter is the fact that they have already decided to give the motor 'bus service, which has been running for only a month or two, a fair trial.

Scarborough.—Under the Tramway Act (1902) the Corporation can subscribe £10,000 towards the company's undertaking. If they do this, or only take £5,000 worth of shares, the mayor becomes *ex officio* director of the company. The Corporation has also the right to purchase the undertaking in 1926 as a going concern without any provision as to percentage. If in any year the undertaking pays a dividend of more than 4 per cent., then the company have to pay to the Corporation a percentage of the profits.

Wolverhampton.—The negotiations which have been going on between the Corporation and the Lorain Steel Company for some two months with reference to the 11 odd miles of tramway which have been equipped on the Lorain surface-contact system are reported to have concluded without an agreement being arrived at. It is stated that the Corporation's offer of £15,000 for the lines has been rejected by the company, who have decided to abide by their claim of £25,000. The matter is to be considered at a full meeting of the Town Council to-day (Friday), but failing agreement, we presume the whole question will be submitted to arbitration.

Additional Traffic Returns.—Anglo-Argentine, £1,234 increase; Barcelona Ensanche y Gracia, £218 increase; Barcelona, £81 increase; Brisbane, £14 increase (month of August, £11,736, increase £294); British Columbia Electric (month of March), gross earnings £10,352, net income £2,658; Buenos Ayres and Belgrano Electric, £431 decrease (month of August, £13,431, increase £533); Calcutta, £375 increase; Cape Town (month of April), receipts £16,003, expenditure £8,313; Isle of Thanet Electric, £193 decrease; Mexico Electric (month of August), receipts £48,600; expenses, £27,900; Perth Electric, £161 increase; Port Elizabeth (month of April), receipts £4,292, expenditure £2,281.

Newport.—It will be proposed at the next meeting of the Town Council that the fares on the electric tramways be altered so as to be ½d. fares on the Malpas-road route from the terminus to High-street, instead of 1d. from the terminus to the centre. At the last meeting Alderman Moses, in bringing up the report of the Tramways and Electricity Committee, referred to a statement that had been made that the tramways were being worked at a loss of £100 per week. An estimate had been prepared, in which the fullest allowance had been made for expenses, which showed that in the five ordinary weeks in which the full service had been running there was a balance of income over expenditure of £11 per week. He asked the Council to give the committee fair play, so that they might have an opportunity to show what the tramways could do now they had been placed upon a substantial business basis.

Digitized by Google

Bolton.—The question of English *v.* Belgian rails was discussed at the last meeting of the Town Council, on a proposal of the committee to accept a Belgian tender for rails. An amendment in favour of accepting the tender of a British firm was ultimately carried by 35 votes to 18.

Portsmouth.—The summary of the tramway accounts for the year ending March 31 last is just to hand, and shows a balance of £6,918. 10s. 8d. to be disposed of. There was an actual balance on the working of £46,988. Of this £32,847 went to the sinking fund and in interest, and after paying other charges £13,064 remained. As the year started with a deficit of £6,146, the actual sum left for disposal is the one stated above. If the committee are wise, it will be retained as a provision for renewal of plant in the time to come.

Sunderland.—The Tramways Committee have recently been making application to the Board of Trade for permission to run at higher speeds than those generally prevailing in the borough. The highest speed at present sanctioned in the town is 10 miles an hour, but this is only in the more thinly-populated parts, and the speeds vary from that figure down to as low as six and even four miles an hour. As this is only the pace of a walk, the committee have felt themselves handicapped in their desire to give a quick service to all parts of the town.

Finsbury.—With regard to the proposal of the London County Council to adopt the overhead system of electric traction from High-street, Islington, *via* Liverpool-road, to Holloway-road, because of certain structural difficulties in connection with the conduit system, the Borough Council have resolved to inform the London County Council that whilst this Council have no desire to raise any difficulty in regard to the electrification of the tramway service, they regard that portion of the borough referred to as unsuited to the adoption of the overhead system, by reason of the narrowness of the thoroughfare.

West Bromwich.—There is an agitation amongst the working classes here in favour of the running of early morning workmen's cars, and also the trial of the system of ½d. fares. Large numbers of workmen in the outlying districts who are employed by firms in Birmingham complain of difficulty in getting to their work. It is stated that the British Electric Traction Company have already given a half promise to give the ½d. fares a trial. The West Bromwich Trades Council have taken the matter up, and have decided to bring pressure to bear upon the Town Council with a view to securing these concessions.

Llanelly.—At the monthly meeting of the Borough Council on Monday a letter was read from the British Insulated Wire and Cable Company repudiating all knowledge of any agreement entered into with the Council for the payment of costs incurred by the Council in respect of the opposition to the Carmarthen Power Bill and other matters. It had been understood by the Council that all these costs would be paid by the Wire Company. Mr. Tom Hughes said that the traction matters in the town had now got into a disgraceful state, and the best thing was to hold a special meeting to consider the position. This was agreed to.

Devonport.—Much surprise is expressed locally that those tramway extensions which have recently received the sanction of the Board of Trade, have not yet been opened for traffic. For the delay, apparently, blame attaches neither to the Corporation Tramways Committee nor to the Devonport and District Tramways Company, who will work the lines in connection with their present system. Up to the present the electric cables have not been tested, and until this is done the company will not open the extensions for public traffic. The lines from St. Budeaux Station to Saltash Passage and from Milehouse to the borough boundary have not yet been officially inspected.

Paris "Tube" Railway.—Parisians, says the *Standard's* correspondent, are but slowly recovering their confidence in the tube railway. Before the terrible accident at the Couronnes Station, the number of passengers carried were from Aug. 1 to 10 between 271,000 and 343,000. On Aug. 11 it fell to 155,000, and whilst the lowest figure since per day has been 143,000, the highest was only 204,000 this day week. Thus, during the first week in August, before the accident, the average per day was 297,000 passengers. From the 11th to the 16th the average fell to 148,000. During the next week, on the 23rd, it rose to 179,000, and last week the average per day was 197,000 passengers.

West Manchester Light Railway.—A meeting of the Davyhulme and Flixton Parochial Committees has been held to consider the plans submitted by the promoters for the construction of the West Manchester light railway, which is to connect the railways at the docks in Trafford Park with Irlam Locks. Hitherto the Davyhulme Committee have intimated that they object to the plans, inasmuch as it is proposed that the lines shall cross the main roads of Davyhulme and Flixton on the level. The Parochial Committee hold that the new railway crossing these roads on the level will cause a great inconvenience to the local traffic, to say nothing of the danger that will arise when the tramlines are laid.

Crewe.—At a meeting of the Electric Lighting and Light Railways Committee the town clerk read a letter from Messrs. Rowcliffe and Co., solicitors, Manchester, stating their intention to make application on behalf of clients in the next session of Parliament for an Act to construct tramways from Macclesfield to Congleton, Sandbach, and thence to the boundary of the borough of Crewe, and if the Council were prepared to favourably consider a scheme for continuing the line from Crewe to Nantwich by Willaston and back through Ledge Field they would be prepared to discuss the matter further, and suggesting that an interview between the engineers and a sub-committee of the Council might be arranged. Another poll on the whole question of the tramways has been asked for.

Bradford-Halifax.—For some considerable time there has been no service of tramcars between Buttershaw and Shelf, the steam cars having been stopped to enable the electrification of the line to be proceeded with expeditiously. That work has now been completed, and already electric cars are running through from Bradford to Shelf. Commencing on Monday last the cars ran direct from Stanningley to Shelf at half-hour intervals. These cars are to be run in connection with the Halifax and Shelf service, so that it will be possible to travel from Leeds to Halifax with only two changes. The cost of the journey from Bradford to Shelf will be 3d. Accordingly, at the cost of 1s. an interesting circular tour may be made from Bradford to Halifax by Queensbury, returning from Halfax by Shelf.

Bradford.—At Tuesday's meeting of the City Council the members were asked to agree to a resolution of the Waterworks Committee to accept the terms mentioned in a provisional agreement made between the Nidd Valley Railway Company, Power and Traction, Limited, and the Corporation for the purchase of the Nidd Valley light railway order, giving power to the Corporation to construct and work a light railway from Pateley Bridge to Lofthouse, with the requisite borrowing power. With respect to the proposed increase of the salary of the tramways manager (Mr. C. J. Spencer) from £500 to £700 per annum, as recommended by the Tramways Committee, an amendment was moved to the effect that the committee's recommendation be rescinded, on the ground that the salary of the tramways manager was fixed for five years by an agreement dated July 20, 1900. The amendment was ultimately defeated by 29 votes to 22.

York.—Speaking on the question of the proposed purchase by the Corporation at the half-yearly meeting of the York Tramways Company on Tuesday, the Chairman said the company "would be prepared to meet them (the Corporation) very fairly, but they thought the Corporation were rather acting the 'dog in the manger' policy, because the Corporation had absolutely refused to allow the company to either work the tramways by electricity or extend them to the suburbs. The company thought that was very unreasonable, and not in the interests of the Corporation, because if they had worked the tramway by electricity they would have been a very large customer for the purchase of electricity, which would have made a considerable difference in the accounts of the Electric Lighting Committee of the Corporation. The directors thought the position a very unfortunate one, certainly not in the interests of the company or the Corporation."

Dewsbury.—Reference was made at the last meeting of the Town Council to the decision of the committee not to entertain, at present, the application of Soothill Upper to co-operate with the Corporation in a scheme for the construction of tramways from Dewsbury Market-place, *via* Crackenedge-lane to Hanging Heaton and Shaw Cross, but it was explained that the reason the committee had come to the decision they had done was because there would be insufficient time to go into the details necessary for the provisional order so far as Soothill Upper was concerned. A special meeting of the Town Council is to be held on the 1st prox. for the purpose of considering the desirability of applying to the Board of Trade for a provisional order to empower the Corporation to construct electric tramways, commencing in Vicarage-road, near the parish church, and passing along Long-causeway, through the Market-place, and up Wakefield-road to the borough boundary, where they will join the yet to be constructed lines of Earlsheaton and Ossett.

South London.—In the electrification of the tramways in South London fresh developments of the work of an important character have been commenced. In Southwark Bridge-road a number of men have begun to tear up the eastern side of the roadway, a temporary line having been previously laid down on the western side. The new portion of the line which is being laid down in the Marshalsea-road, to connect the lines between the Borough High-street and Southwark Bridge-road, is also being proceeded with rapidly, while in that portion of Southwark Bridge-road which runs right up to the bridge itself the metals have been laid down and the necessary junction lines made for the trams to resume the return journeys. When the lines running round the Marshalsea-road and down Southwark Bridge-road nearly to the Elephant and Castle have been completed, one of the most important developments of the new electric system of trams in South London will be ready for use, and new services will be commenced which will run from Streatham and Brixton, New Cross and Camberwell, and probably Balham and Clapham, direct to the foot of Southwark Bridge. The new line along St. George's-road, between the Elephant and Castle and the Westminster Bridge-road, is also being rapidly laid down, and when completed will enable the trams from New Cross and Camberwell to proceed *via* this wide thoroughfare, and so ease the congestion along the London-road and at the Obelisk.

London Rapid Transit.—The *City Press* states that Mr. Yerkes is again on the move with one, if not two, new "tube" schemes. One of these, it is definitely stated, embodies a proposal for a "tube" which, having the Mansion House for a starting point, will proceed along the Strand, and there join up with the other railways in the Yerkes combination. Nor is the London County Council idle in the matter of prospective Bill legislation. It is generally understood that in the ensuing session the Spring-garden authorities will promote a couple of measures dealing with the vexed and difficult problem of locomotion in the Metropolis in particular, and Greater London in general. In their main features both schemes have already been submitted to Parliament for consideration, and will, therefore, come by no means as strangers to the committees in Lords and Commons. One thing is quite certain—viz., that another determined effort will be made to obtain powers to run tramways along the Embankment, and thence over Westminster Bridge. In connection with the Embankment scheme, it may also be mentioned that the Council further propose to seek for powers to extend their surface system in various directions—a step, by the way, that will necessitate the widening of several thoroughfares. Naturally, the question of the subway for trams from Theobalds-road to the Embankment, by way of Southampton-road, Aldwych, and the Strand, will again crop up when the Bill comes on for consideration. Last session,

Digitized by Google

it may be remembered, Parliament authorised the construction of the subway, but at the same time it refused powers to run tramways further than a point at the junction of the Strand with the new street now in course of formation. To give practical effect to the scope of the Embankment proposal, this decision, it will at once be seen, will have to be revised in the event of the Bill passing through both Houses, inasmuch as the one part of the scheme is essential to the other if the object aimed at is to be achieved. Happen what may, there is at least every prospect of a very determined fight between the conflicting interests at St. Stephen's in the coming year.

Johannesburg.—The special correspondent of the *Sheffield Daily Telegraph* at Johannesburg has sent his paper a long account of the proceedings of the Town Council on the 16th ult., when the subject of tenders for the tramways was under discussion. As will be seen from our "Tenders Accepted" columns, one or two English tenders were accepted for steelwork, but we regret having to record that the main order for rails will go to Belgium. The real fight lay between Messrs. P. and W. MacLellan and the Brush Electrical Company, the latter representing the interests of the Société Anoyme d'Augres for grooved rails. In a report on the tenders the town engineer, Mr. D. W. Leitch, stated: "For grooved rails and fishplates there is practically no satisfactory British tender at a reasonable rate. The lowest of such tenders is that of Messrs. MacLellan and Co. Messrs. Mordey and Dawbarn (who had also reported on the tenders) pointed out that, comparing it with the lowest foreign offer f.o.b. at port of shipment, the difference in cost is about 11 per cent. If, however, the same basis for freight charges be taken in the two cases, the difference comes down to about 3 per cent. A more important objection lies in the fact that Messrs. MacLellan's tender is for rails of much softer quality than that specified for. If British manufacturers insist on prescribing the quality of the goods which they are willing to supply, instead of making what their customers ask for, they can hardly complain if they fail to secure orders. Messrs. MacLellan also offer rails of British standard section at 2s. less per ton, but as the weight of these considerably exceeds what is specified, this alternative cannot be recommended on economical or other grounds." Discussing the tenders for Vignoles rails and fishplates, Mr. Leitch takes into account the fact that it is considered British rails are probably worth 10s. more a ton than those of Belgian manufacture, and if allowance be made for this he works out the difference between Messrs. Cammell's tender and the lowest tender at about £200 in favour of the foreign rails. During the discussion it transpired that the difference in the tender of Messrs. MacLellan and that of the Brush Company was over £3,000, but on an amendment in favour of the English tender the voting was equal, until the Chairman gave his casting vote in favour of the foreign tender.

Brighton.—By 25 votes to 22 the Town Council at their last meeting confirmed their decision at a previous meeting to construct tramways in Preston-road. The tramway along Dyke-road is to be constructed with Corporation labour, under the supervision of Mr. J. B. Holliday, the tramways manager. According to the statement of accounts for the year ended March 31, 1903, the amount authorised in loans was £221,170, all of which has been borrowed with the exception of £20,946. The total expenditure on the capital account is given at £205,041. 16s. 5d., of which sum £181,378. 4s. was expended prior to March, 1902. The revenue account provides some very interesting figures. Traffic expenses are given at £23,575. 15s. 5d.; repairs and renewals, £4,426. 19s. 10d.; management expenses, £2,676. 7s.; rates and taxes, £237. 15s.; special expenses (insurance and law), £698—making a total expenditure of £31,615 8s. 1d. On the other side, the traffic receipts show that 10,432,528 penny fares were paid, producing an income of £43,468. 17s. 4d. A further sum of £231. 6s. was received as rents of malthouses and premises in Viaduct-road, so that the total income was £43,700. 3s. 4d., which left the substantial balance of £12,084. 15s. 3d. to be transferred to the net revenue account. This account shows that last year there was an adverse balance of £3,051. 5s. 11d. The other items on the debtor side are £6,170. 15s. 11d. for interest, £1,779. 0s. 3d. sinking fund charges, and a balance of £4,134. 19s. 1d., being a surplus on the revenue account at March, 1903, to be carried to the next account. The creditor side shows that the deficiency has been paid off. The general balance-sheet shows the following liabilities: redeemable stock, £147,592. 11s. 1d.; debenture debt, £48,224; premiums on stock issued, £3,407. 8s. 11d.; floating liabilities, £11,301. 17s. 9d.; revenue account, £4,134. 19s. 1d.; surplus account (amount of loans paid off), £1,000—total, £215,660. 16s. 10d. The assets are given as follows: capital outlay, £205,041. 16s. 5d.; stores in hand, £3,472. 5s. 4d.; floating assets, £7,146. 15s. 1d.—total, £215,660. 16s. 10d. After last year's deficiency has been paid off it will be noticed there is still a balance to the good of £1,083. 13s. 2d., and it is proposed that this should be a nucleus of a special fund to be styled the depreciation and contingency reserved fund.

Underground Electrification.—A railway expert has written to the *Financial Times* with reference to the following passage, which occurred in a leading article in that paper's issue for the 8th inst. The passage read: "At one time it was not possible to regard the electrification proposals with unstinted approval. There was once a distinct danger that the Inner Circle, instead of being a self-contained system, worked in the interests of the two owning companies—the District and the Metropolitan—would become disjointed by the adoption of two distinct systems of electric traction. That danger has disappeared and a joint committee of the two Boards has been appointed to ensure uniformity in equipment, etc." The correspondent says: "My information, unfortunately, leads me seriously to doubt whether the danger of discord between the two companies in the working of the Inner Circle is so completely a thing of the past as this article states. Mr. Perks has, indeed, stated publicly quite lately that the two managements are by no means in agreement as to the future of the Circle traffic, the Metropolitan wishing greatly to increase the number of trains which run round the Circle when the electrification is complete, whilst the District authorities attach greater importance to developing the through east and west service which they have recently established in conjunction with the Tilbury Company. But this is not all. Despite the appointment of a joint committee of the two Boards to harmonise the electrification of the two lines, there is yet grave danger of a want of uniformity in their respective electrical equipments. The *Financial Times* has already chronicled the letting of the District's 'multiple-unit' contract to the British Thomson-Houston Company; but the Metropolitan, if my information be correct, had already contracted to adopt the rival system of the great Westinghouse firm. In principle, it is true, these two methods of electric train control are very similar, but there are considerable differences in mechanical details between the two, and if the Metropolitan trains are equipped with the one and the District's with the other, any interchange of rolling-stock between the two companies will be rendered quite impracticable. Also, if the joint 'electrification' committee of the two Boards be really an active body, it seems strange that the Metropolitan authorities have not kept themselves more closely in touch with the exhaustive tests of the respective merits of the Westinghouse and Thomson-Houston train-control systems which have been going on for some four months past on the Ealing and Harrow section of the District. I hear that the Metropolitan made some tests of their own at Neasden before deciding to let their contract to the Westinghouse Company, whereas the District's tests at Harrow resulted . . . in favour of the Thomson-Houston system. But surely this was a matter coming within the sphere of action of the joint committee of the two Boards, who might have been expected to have taken some steps to ascertain why similar experiments on the two lines led to such contrary conclusions. Which of two rival firms obtain a contract of this sort is no concern either of the shareholders or of the public; but that the better of the two systems should be selected, and that there should be no needless sacrifice of uniformity, are matters of vital public concern."

PROVISIONAL PATENTS, 1903.

AUG. 31.

18710. Chambers for the combustion of fuel under pressure, valves, purifiers, loading apparatus, and air-compressors in connection therewith; means for applying the gaseous products to smelting, steelmaking, and the production of electricity. David Cook, 30, Lancaster-park, Richmond.

18712. A double point for electric rails of the conduit system so that the car can always pick up the current. Alexander Cass Holbrow, Holmwood House, Grove-vale, East Dulwich, London.

18713. Automatic working of points of electric tramways. Alexander Cass Holbrow, Holmwood House, Grove-vale, East Dulwich, London.

18731. Improvements in electrical switches. Henry Crowe, 53, Chancery-lane, London.

18740. A method of actuating switches or the like. William Edward Evans, 27, Chancery-lane, London. (Allgemeine Electricitäts-Gesellschaft, Germany.) (Complete specification.)

18745. Improvements in and relating to excess indicators for use with an electric current. Llewellyn Birchall Atkinson, 1, Queen Victoria-street, London.

18754. Improvements in semi-automatic telephone systems. Ernest August Faller, 19, Holborn-viaduct, London. (Complete specification.)

18755. Improvements in or relating to electrical indicating apparatus for communicating and recording instructions. Heinrich Blender, 37, Essex-street, Strand, London. (Complete specification.)

SEPT. 1.

18818. Improvements in voltmeters and ammeters. Amos Lawrence Weekes, 55, Chancery-lane, London.

18829. Improvements in electric insulators. William Edward Langdon, John Crisp Fuller, and George Fuller, 33, Chancery-lane, London.

18841. Improvements in selective systems for electrical communication. Sylvanus Albert Reed, 55, Chancery-lane, London. (Complete specification.)

18853. Improvements in and relating to relays. James Tarbotton Armstrong and Axel Orling, 323, High Holborn, London.

18854. Improvements in and relating to telegraphic recording and perforating apparatus. James Tarbotton Armstrong and Axel Orling, 323, High Holborn, London.

18860. Improvements in and relating to electrical switches. Louis Marino Casella, 1, Queen Victoria-street, London.

18867. Improved telegraph apparatus. Oliver Imray, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Société des Telegraphes Multiplex Systeme E. Mercadier, France.) (Complete specification.)

SEPT. 2.

18907. Improvements in electrical controllers. Wallace Fairweather, 62, St. Vincent-street, Glasgow. (Diehl Manufacturing Company, United States.) (Complete specification.)

Digitized by Google

18934. Improvements in electric storage batteries or accumulators. Henry Pratt and Frederick Vince, 1, Portland-street, Wardour-street, London.

18953. Improved check or indicator applicable to the electric controllers of electrically-driven vehicles. August Richard Louis Wille, 40, Chancery-lane, London. (Complete specification.)

18953. Improvements in and relating to electrolytic manufacture of caustic soda and other products. James Ballantyne Hannay, 18, Southampton-buildings, Chancery-lane, London.

SEPT. 3.

18964. Improvements relating to the regulation of the voltage of dynamos. Charles Turnbull, jun., 34, Castle-street, Liverpool.

18980. Improvements in and connected with electrical signalling on railways and tramways. James Wood Tunstall, 10, St. George's-crescent, Liverpool.

18998. Electric current generating and motive power machine. Walter Shelverton Frost, 135, High-street, Homerton, London.

19012. Improvements in electric lampholders. Victor Zingler, 20, Sarre-road, West Hampstead, London.

19015. Improvements in contacts especially suitable for induction coils. Marconi's Wireless Telegraph Company, Limited, and Edward Priddle, 24, Southampton-buildings, Chancery-lane, London.

SEPT. 4.

19029. Improvements in switch trolley heads for electric cars. James Henry Armstrong McGuire, 221, Belle Vue-avenue, North-lane, Roundhay, Leeds.

19053. Improved method of guiding trolley heads along frogs and crossings attached to overhead wires in connection with electric railways and tramways. Horatio Cooley, 52, Luther-street, Leicester.

19054. Improvements in and applicable to overhead equipment, electric or otherwise, of railways and tramways, to work in connection with railway carriages, tramway car or cars, or vehicle or vehicles, truck, trucks, or part or parts of the same. William Pettinger West Weatherill, 33, Beech-street, Waterloo-road, Cheetham, Manchester.

19063. Improvements in and relating to electro-capillary detectors, relays, and recording apparatus. James Tarbotton Armstrong and Axel Orling, 323, High Holborn, London.

19065. Improvements in or relating to electrical measuring instruments. Charles Edwin Foster, Edwin Rudolf Grote, and Milton Victor Ely, 165, Queen Victoria-street, London.

19092. Improvements in electrical locking apparatus for railway signals. William Robert Sykes, jun., 53, Chancery-lane, London.

SEPT. 5.

19139. Improvements in incandescent gas and electric globe lamps. John Westwood Lea and John Hall Perrins, Midland Works, Bracebridge-street, Birmingham.

19142. Improved driving and speed-regulating mechanism for dynamo-electric generators when carried by railway and other vehicles. Alfred Townley Metcalf, 17, Hanover-street, Keighley.

19172. Improvements in apparatus for controlling the working of electrically-driven cars. Siemens Bros. and Co., Limited, and Francis Lydall, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

COMPLETE SPECIFICATIONS ACCEPTED.

To be published September 24, 1903.

1902.

19368. Electrodes for electrolytic purposes. Hargreaves.

19562. Emergency brakes. Lake. (General Electric Company.)

19566. Electric switch regulators. Lake. (General Electric Company.)

19655. Alternating-current meters. May.

21488. Trolley heads for electric tramcars to guide the live wire into the groove of pulley when changing the direction of car. Cook, Cook, and Partington.

21913. Alternating-current motors. Schüler and Ferranti Limited.

22327. Incandescent electric lamps. Soc. Anon. la Lampe Hollub. (Date applied for under International Convention, Nov. 30, 1901.)

22329. Electro-pneumatic controlling systems for railway vehicles. Le Tall. (Westinghouse.)

23116. Current regulators for use in connection with the charging of storage batteries and for other purposes. Niblett.

23491. Magnetic wheels. Heinze. (Date applied for under International Convention, Feb. 24, 1902.)

26106. Combined lampholders and switches for glow lamps. Davies.

23666. Maximum current registering indicators. Isabella Christina Clark, Alfred John Davies, and William Livingstone Russell (executrix and executors of Alexander Melville Clark). (Hartmann and Braun.)

26163. Electrical cut-outs. Evered and Co., Limited, and Evered.

27184. Devices for operating electrically the points on electric tramways and railways. Tierney and Malone.

27887. Magneto-electric ignitors for internal-combustion engines. Tangye Tool and Electrical Company, Limited, and Bate.

27957. Electrical apparatus for controlling signals on railways and the like permanent ways. Weiss.

28322. Telephone exchanges. Cohen.

1903.

7191. Means for protecting underground cables or conduits against being damaged. Rayner. (Wilhelmi.)

8488. Magneto-electric generators. Remy and Remy.

11738. Telephone switchboards. Lake. (Elektriak Bureau.)

12683. Underground or conduit systems for electric tramways and railways. Cope.

14888. Electric motors. Klemm and Reiss.

15929. Road vehicle for conveying electric cable drums and other cylindrical bodies. Jones, Jones, and Sedwell.

15955. Charge indicators for secondary batteries. Maxim. (Date applied for under International Convention, Aug. 4, 1902.)

16569. Field magnet for electrical machines. Hearson. (Electric itäts-Geßellschaft Alioth.)

NOTES.

Books Received. — "Governors and Governing Mechanism," by H. R. Hall (2s. 6d.), and "The Manufacture of Iron and Steel Tubes," by Edward C. R. Marks (5s.), published by the Technical Publishing Company, Manchester.

Dr. Fleming's Cantor Lectures.—Many of our readers will no doubt be interested to hear that Dr. J. A. Fleming's Cantor lectures on "Hertzian Wave Telegraphy," recently delivered before the Society of Arts," can now be had in pamphlet form at the price of 1s. a copy. Application should be made to the secretary of the society, Adelphi, W.C.

Electricity for Australian Railways.—There is considerable talk of adopting electric traction on some of the railways in the State of Victoria in the Australian Commonwealth, particularly on the suburban railway system of Melbourne. The possibilities of the proposed change from steam to electric traction have been the subject of discussion with the Railway Commissioners of that State for some time past. The matter has also come under the notice of the Victorian Parliamentary Standing Committee on Railways, and a sub-committee of that body has been appointed to make enquiries on the whole subject. The committee is now busily prosecuting its enquiries in Sydney, where, as our readers know, a large scheme of conversion from steam to electric traction on the State tramways is nearing conclusion. It is the opinion in Victorian railway circles that electricity could be advantageously adopted on several of the lines now worked by steam power.

North-East Coast Institution. — We have to acknowledge parts 8 and 9 of vol. xix. of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders. This issue, in addition to a couple of papers relating to steamship vibrations and the construction of large steel steamers, contains some valuable remarks by Mr. John Tweedy and others on education in technical science and the general training of youths. In this connection it may not be generally known that the Institution has appointed an educational committee to consider questions which may arise in regard to the education in technical science and general training of youths entered or preparing to enter engineering and shipbuilding works, to discuss such questions with public and other educational bodies, and to advise upon them. The committee has been empowered to associate itself by sub-committee or otherwise as may be arranged with similar committees of kindred institutions.

American Institute.—The latest volume of the *Transactions* of the American Institute of Electrical Engineers has just reached us. It opens with a full account of the proceedings of the 177th meeting held in New York, at which the annual report of the board of directors was presented. We are pleased to be able to record the great advance which the American Institute has made in the matter of numbers. In the past year the membership has nearly doubled, the total number of members of all grades being close on 740, compared with 390 the previous year. This increase is no doubt due to the establishment of several local sections—nine in number—all of which have been successfully launched during the past year. Among the papers which are reprinted in this volume are the following: "Experimental Basis for the Theory of the Regulation of Alternators," by Mr. B. A. Behrend; "Study of the Heyland Machine as Motor and Generator," by Mr. C. A. Adams; "Compounding of Self-Excited Alternating-Current Generators," by Mr. A. S. Garfield; "Alternating-Current Theory," by Mr. W. S. Franklin; and "Some Features of Telephone Traffic," by Mr. J. G. Wray.

Wind Power.—For more than two years two small factories, one near Leipsic, the other near Hamburg, have been driven successfully by windmills, which are also used as a means of generating electricity for lighting purposes. According to the *Elektrotechnischer Anzeiger*, the windmills have a diameter of 5m. and 5½m. respectively, and are mounted on the roof of the works. To ensure reliability the wind wheel itself has no moving parts, the speed regulation being obtained by turning the windmill so as to vary the angle under which the wind impinges upon the sails, which are built of steel sheets. This is performed by a small auxiliary wind motor, and is said to be done so quickly and accurately that the voltage of the dynamo remains practically constant throughout the range of ordinary wind pressures. An automatic switch cuts out the battery connected in parallel with the dynamo as soon as the wind falls below a certain point. In one of the cases mentioned the battery may be divided into two parallel groups when it is necessary to utilise unusually low winds.

Paris Metropolitan Railway.—Appearances incline to the belief that the question of possible reforms on the underground electric railway in Paris after the recent disaster, will lead to a state almost approaching open rupture between the Municipal Council and the railway company. We have already enumerated the various recommendations of the special committee of enquiry as to what precautions should be taken against future accident, and it seems that the Permanent Metropolitan Railway Committee of the Municipal Council have authorised the committee of enquiry to see that they are carried out. In addition, the Municipal Committee have passed a resolution in favour of the municipal officials entrusted with the control and inspection of the Metropolitan being empowered to exercise this control in a permanent fashion over the traffic and management. The relations between the two principal authorities are thus considerably strained. Although the city has a right to see that precautions are taken to prevent, as far as possible, the recurrence of serious accidents, and the city is in partnership with the company, the cost of the suggested reforms will have to be borne entirely by the latter, for the partnership exists only to the extent that the city receives about one-third of the gross receipts.

London Traffic Enquiry.—The Royal Commission which was appointed some months ago to enquire into the subject of locomotion in London generally, has already covered much of the ground of its enquiry in the Metropolis; and the great mass of evidence which it has been enabled to collect at its weekly sittings will no doubt prove of the utmost value when the time comes to make a report. The many and important sources of information on this subject of locomotion, however, have by no means been exhausted, and after the parliamentary recess the Commission will return to its labours in London. In the meantime the Commission has wisely decided to pay a visit to the States, where, it is admitted, the most up-to-date practice in electric tramway and railway work prevails. Mr. L. L. Macassey, the secretary to the Commission, is now in New York making arrangements for a tour of the principal cities in the States, and the members of the Commission forming the party leave England this week. We are sure the Commission will receive every courtesy during their American tour from engineers on the other side, and there is little doubt but that it will derive great benefit from an investigation of

Digitized by Google

the systems of traction and transport as they exist in the United States to-day.

Electrically Operated Swingbridge.—Sydney, in New South Wales, will soon be in possession of a swingbridge, operated electrically, to replace the present Pyrmont Bridge. The swing span of the new bridge, which is now under construction, will be 225ft. long and 54ft. wide, and will weigh 600 tons. The swing is of the ring bearing type, and the whole weight—some 800 tons when swinging—is distributed by an arrangement of girders to 16 points on the drum, thus ensuring an even load on 66 cast-steel rollers upon which the span travels. Two 50-h.p. motors will be provided for operation, and it is estimated they will either open or close the bridge in 60 seconds. Both slewing and end-lift motors will be carried on a platform inside the drum, the former working, through a chain of gears, a vertical shaft, on the lower end of which is a cast-steel pinion meshing with a cast-steel rack secured to the top of a pivot pier, while the end lift will be effected by means of cones on horizontal shafts worked by a 35-h.p. motor geared to a longitudinal shaft running the whole length of the pier. The whole of the operations connected with the swing span and the gate on the side span will be controlled by one man from the controller house over the footpath of the centre of the swing span. The new swing will afford two clear fairways of 70ft., as against the 57ft. 6in. and 35ft. openings as at present.

Magnetic Separation.—The use of magnets for the separation of para-magnetic particles from other materials is of considerable practical value in different manufacturing industries. The idea is employed, for instance, in attrition machines, which are used for grinding rice chaff into small particles, to be mixed with more nutritious ingredients, to make cattle food. These attrition machines consist of two metal discs turning in opposite directions, being separated by $\frac{1}{8}$in. to $\frac{3}{16}$in. The discs are indented to give a grinding surface, and with each revolving at a rate of from 1,500 to 2,000 revolutions a minute, it can readily be seen that iron or steel particles in the light chaff ground between the discs may cause sparks which would give rise to a destructive fire. To extract such particles, the chaff, before reaching the discs, is passed in close proximity to strong magnets, which attract any bits of metal with enough force to draw them from the chaff. A similar contrivance has been used in flour mills, where it is well known that a slight spark will oftentimes cause a violent explosion of the fine dust which collects in flour mills. A third application of magnetism, according to the *Western Electrician*, is adapted for paper-pulp manufacture. It is embodied in a recent invention by Charles J. Reed, of Philadelphia. To extract the particles of metallic substances from the pulp, a cylindrical shell is arranged to rotate in the pulp tank or trough. Stationary magnets within the shell are so mounted that the pulp, as it is tossed about by the rotation of the shell, comes in contact with the magnets some time during its passage, and all para-magnetic substances are thus separated from the remainder of the mass.

Colonial Patents.—Both Australia and Canada have been amending their patent laws within the past 12 months, with, however, but indifferent success. In each case the objection is placed on the same ground, the main provision being practically identical, with the exception of the term of years named. Thus, in the case of the Australian Federal Patents Bill, of which we gave some particulars last week, it is laid down that the patentee, or some person authorised by him, shall, within five years after the date thereof, commence, and after such commencement continuously carry on, in Australia the construction, manufacture or working of the invention patented in such a manner that any person desiring to use it may obtain it, or the use of it, at a reasonable price. A further proviso is that after four years the patentee shall not import the invention, or cause it to be imported in Australia. The Canadian Bill is practically in the same terms with this difference, that the period in which the patentee must commence to manufacture is limited to two years, and he is not to be allowed to import into Canada the invention for which the patent is granted after the expiration of 12 months. These conditions are so widely different from the law as it stands to-day in this country, and they are likely to so seriously affect the position of British patentees, that a good deal of opposition is being shown to the proposals. It follows from the above that an English manufacturer who obtains a patent for his product in the Australian Commonwealth must actually manufacture on the spot, and refrain from exporting the same from this country after a period of four years, or lose his patent. In the case of Canada it is even worse, the period being limited to two years for working the patent and one year for importing the article.

French Telephones.—There is a good deal of adverse criticism going on in France just at present concerning the telephone question. Probably in no other Continental country has the telephone made such advances in public and private life, and this fact perhaps largely accounts for the present inadequacy of the system. As an example the Telephone Department of the French Government shows that the receipts increased from £995 in 1885 to £930,700 in 1899. The fault seems to lie, not in the paucity of the receipts, but in the manner of their disposal. Thus the bulk of the profits goes to help the Budget, and only a small fraction is set aside for improvements and extensions. The result is a clamouring outcry on the part of the people for better facilities. These the authorities declare their inability to provide owing to lack of funds, and undoubtedly the financial question is the root of all the evil. Last April the Government introduced a Telephone Extension Bill in the Chamber of Deputies, but no action has been taken by Parliament. The proposal is to obtain a loan of nearly a quarter of a million sterling with which to carry out the much-needed improvements. The Telephone Department is confident that it could repay the amount in less than five years, but the Legislative Assembly appears to be in no hurry to discuss the proposal. As an example of the inadequacy of the present system, we may quote an instance in which a subscriber only succeeded in obtaining communication with Paris from a provincial town 24 hours after ringing up. We are assured that such instances as this are not infrequent when communication is required with the capital from one of the favourite French seaside resorts, such as Trouville. No wonder, then, that there the public is dissatisfied. In this case it is the Government that is responsible for providing the telephone service of the country, but we are curious to know what would happen if the undertaking were in the hands of the private company?

Russian Electrical Industry.—In our last issue we dealt with this subject from the point of view of the good progress which is being made in Russia in the application of electricity to commercial purposes. We endeavoured to show that its use as a motive power in factories and works, and also for lighting purposes, has already advanced with rapid strides, so much so that the bulk of the electrical machinery has to be imported, the home manufacturers being unable to meet the demand.

Digitized by Google

In the light of these facts it is a curious circumstance that the electrical industry, as an industry, is having an unfortunate experience in Russia at the present time. Most of the German electrical companies which have established branches in Russia have but a sorry tale to tell. The majority of these branches have so far resulted in heavy losses, whether conducted as sales bureaux for their original promoters or whether formed as Russian companies with workshops in that country. In this connection Prof. Salomon, general manager of the Lahmeyer Electrical Company, of Frankfort-on-the-Maine, which has incurred a loss of over £140,000 in the past two years, told the shareholders at the annual meeting the other day that all the German electrical companies with Russian branches had been disillusioned, but that scarcely anything better was expected from connections with other companies. Instead of the prospect of an early improvement in the present state of affairs, things look like going from bad to worse. It is stated that the purely Russian electrical companies have forwarded a petition to the Government praying that new branches of foreign works should no longer be permitted to be established, and that the foreign branches already located in Russia should be excluded from participating in competitions for public contracts in that country. The apprehension seems to be that if the petition receives sufficient support, the Government may be disposed to sanction the application. The result would be to practically close most of the German branches in Russia, while the position of those already formed as Russian companies would be jeopardised.

Precipitation of Colloidal Solutions.—Mr. H. Freundlich describes in a recent paper an investigation into the precipitation of colloidal solutions by electrolytes. Colloidal solutions of arsenious sulphide, ferric hydroxide, and platinum were employed in this investigation, and the precipitating power of various salts was compared by determining the concentration of the salt solution that, within a given time and under otherwise equal conditions, caused a separation of flocks large enough to be kept back completely by a filter of a standard type. For colloidal solutions exibiting anodic convection under the influence of a current (arsenious sulphide and platinum), the precipitating power of a salt is practically independent of the anion, the valency of the cathion being the determining factor. Tervalent ions are more effective than bivalent ions, and these again are more effective than univalent ones. For a colloidal solution of ferric hydroxide which exhibits colloidal convection, the valency of the anion is the chief determining factor. Further, in the case of the univalent ions, an influence of the rate of migration may be detected; thus, in the precipitation of a collodial solution exhibiting anodic convection, the acids are more effective than the salts yielding univalent cathions. Speaking generally, equivalent solutions of equally dissociated electrolytes, yielding ions of the same valency and with nearly equal rates of migration, are equally effective in the precipitation of collodial solutions. It has been shown that the precipitating effect is dependent not only on the concentration of the precipitating salt, but also on the rate at which the latter is added to the colloidal solution. This leads the author to regard the process in question as one involving the element of time (as a process of diffusion); it cannot be explained by a displacement of the statical equilibrium. As a working hypothesis, the author supposes the colloidal substance to be semipermeable to the ions, the character of the semipermeability being closely bound up with the direction of the convection (anodic or cathodic). We take the above from an abstract in the Chemical Society's *Journal*.

Aluminium Conductors.—One of the chief objections in the way of the general use of aluminium for electrical conductors is the difficulty of obtaining a satisfactory joint, but this has apparently not stood in the way of the adoption of aluminium conductors on some of the North American transmission lines. Indeed, aluminium has now almost entirely displaced copper on the three longest electrical transmission systems in that country. The longest single line in California—that from Electra power-house to San Francisco, a distance of 154 miles—uses aluminium entirely, while the 144-mile transmission line between Colgate and Oakland is accomplished with three aluminium and three copper wires. Again, the Shawinigan Falls-Montreal transmission over a distance of 85 miles is carried out with three aluminium conductors alone. In the face of these facts, Mr. Alton D. Adams in the *Engineering Magazine* claims that not only has copper lost its former place as the only conductor to be seriously considered for transmission circuits, but that aluminium has actually gained the most conspicuous place in the long-transmission work. The decisive factor in this victory of aluminium has been that of cost for a circuit of given length and resistance. From the standpoint of cross-sectional area, aluminium is inferior to copper as an electrical conductor. Comparing wires of equal sizes and lengths, the aluminium have only 60 per cent. of the conductivity of the copper. The inferiority of aluminium as an electrical conductor in terms of sectional area is more than offset by its superiority over copper in terms of weight. One pound of aluminium drawn into a wire of any length will have a sectional area 3·33 times as great as 1lb. of copper in a wire of equal length. This follows from the fact that the weight of copper is 555lb., while that of aluminium is only 167lb. per cubic foot, so that for equal weights the bulk of the latter is 3·33 times that of the former metal. Hence, for equal resistances, the weight of an aluminium is only one-half as great as that of copper wire of the same length. From this fact it is evident that when the price per pound of aluminium is any less than twice the like price of copper, the former is the cheaper metal for a transmission line of any required length and electrical resistance

Cooper-Hewitt Vapour Lamp.—A notable improvement has quite recently been added to the Cooper-Hewitt mercury vapour lamp, which has already been illustrated and described in this journal. The improvement consists of a new method of starting, and an interesting account of it is given in the *Electrical World*. Up to the present the lamps put into commercial use have been started by a high-potential kick from an inductance coil. A special quick-break switch under oil was used to make and break a circuit across the coil, the discharge of which passed through the lamp, breaking down the initial reluctance to starting. The new process of starting is known as the "tilting" method, and is somewhat similar to that employed by Arons and other early investigators, in that an absolute connection is established between the two electrodes of the lamps by means of the fluid of the electrodes themselves. In the Hewitt lamp the electrodes are placed one above the other, and a connection is established by first tipping the lamps so that there is an excess of mercury in the normal upper electrode, and then allow ing the mercury to flow by gravity in a stream down the length of the tube. This stream momentarily establishes a metallic connection between the electrodes and then breaks, usually at the bottom, where it ends in a spray. The lamp lights across the break, the luminous area rapidly extending up the tube as the stream falls away. The liquid mercury has the property of stringing out into a

Digitized by Google

long, fine, continuous stream, and lamps over 4ft. long have been lit in this manner using no more mercury than is required for their normal operation. It is usual, however, to use lamps about 2ft. long to operate on 55 or 60 volts. To operate on 110-120 volts, the lamps are connected two in series. If it is intended to light both lamps simultaneously, they are mounted in one frame and tilted together. With an apparatus of this kind, a simple rheostat and choke oil for resistance are all that is required. When the lamps are to be lighted independently, each is furnished with a resistance having in shunt across the vapour lamp another resistance which is automatically cut out when the lamp is started. Two 40-volt, 1·5-ampere incandescent lamps are used as the shunt, so that being first turned on by an ordinary switch the operation of tilting the vapour lamp may be readily accomplished in an otherwise dark place. They also serve as pilot lamps to show when the switch is left closed and the vapour lamps unlit.

Wireless Telegraphy.—Another international conference on this subject has been arranged to be held in Berlin next year, by invitation of the German Emperor. It is assumed that in the meantime further developments will be made in the art, which will enable the countries represented to view the question of an international agreement from a more practical standpoint. The recommendation agreed to at the last conference, that all coast stations would be obliged to receive and forward wireless telegrams without distinction of system, will probably remain in abeyance until a more definite conclusion can be arrived at. England and Italy have all along stood out against any such proposal, and it will be interesting to see what line of action those countries will take at the next conference. The American Press is greatly exercised over the failure of the preparations made by the Marconi and the De Forrest Wireless Telegraph Companies to send reports of the progress of the America Cup race to the shore. The managers of the two companies insist that their instruments were rendered useless by the efforts of some evil-disposed persons who transmitted at the same time nonsensical rhymes, letters of the alphabet, and meaningless expressions, so that their instruments recorded nothing but a jumble of incoherences. The president of a rival corporation, at whom these inuendoes are supposed to be aimed, retorts that the trouble arose through the transmission of their own bickerings, which, he declares, went on during the whole time of the races. Mr. Marconi, on his arrival in New York the other day, was "cornered" by the interviewers, with the result that some high-flown reports have been circulating among the English newspapers. Among other things, Mr. Marconi is stated to have said: "The four new inventions that I have made will not only make it impossible for anyone to interfere with our messages, but will obviate the necessity of sending and receiving messages from great altitudes. They also make it possible to reduce greatly the amount of current necessary for the transmission of the messages. It will also now be possible to establish a great many more stations, as the height is not so important a consideration. Because of the convexity of the earth, it was formerly necessary for us to transmit messages from a great height in order to avoid the interference of the obstructing land or water. I am of the opinion that we have now overcome every obstacle to the successful establishment of our system on a commercial basis that will prove of great value to the business and scientific world." We can only trust that Mr. Marconi's hopeful prognostications will be realised.

Large Transformer.—*Scientific American* describes in its current issue what is styled the largest transformer ever built. It has been constructed for the Pittsburg Reduction Company, and will be used at their Niagara plant for the manufacture of aluminium by the electric process. The transformer is rated at 2,000 kw., which is said to be 250 kw. more than the capacity of any other transformer. But more remarkable still is the large current which is induced in the secondary winding, it being required by the peculiarities of the aluminium process, in which the current used may be very heavy, though the voltage must be low. The primary winding of the transformer is designed to receive a current of 908 amperes at 2,200 volts, and this will be transformed in the secondary winding to a current of 40,000 amperes at 50 volts pressure. At its base the transformer measures 7ft. 2in. square, and its height is 8ft. 8in. Several details of the construction are interesting in view of the unusual capacity of the machine. The secondary winding consists of heavy laminated copper bars, a large size being required to carry the enormous current for which the transformer is built. These bars obviously cannot be bent to form coils in the ordinary sense of the word, but are connected at the top and bottom by copper plates clamped thereto. The primary winding of the transformer is made up of copper ribbon coil sections, a coil section being placed between each successive pair of bars in the secondary winding. Taps from each coil section of the primary winding are run up to a switching device called the "regulator head," whereby any number of coils may be cut in or out to change the voltage to any pressure desired, the ratio between the primary and secondary voltages being, of course, directly proportional to the number of turns in each. The iron core consists of thin sheets of soft iron built up about the coils. The upper part of the apparatus, after the core is in position, is surrounded by a coil of piping through which cold water is circulated to carry off the heat generated by hysteresis and by the resistance losses caused by the current in the conductors. An additional coil is placed above the primary winding and within the secondary winding. The entire apparatus is encased in a tank filled with oil, which circulates through the transformer and carries the heat from the lower heated sections to the top, where it is taken up by the cooling coils. The oil also serves as an insulating medium in the gaps between the coil sections and between the coils and the iron core. These parts are also separated from each other by sheets of insulating material. The transformer was built by the Stanley Electric Manufacturing Company, of America.

Electrical Coal-Cutting.—Chief interest at the recent annual meeting of the Institution of Mining Engineers held at Nottingham centred on the subject of coal-cutting by electrical methods, which was exhaustively dealt with in a paper by Mr. W. Walker. He showed that coal-cutting by machinery was developing but slowly at the present, but predicted in the near future it would become an urgent necessity. However, the introduction of such machinery could only be successfully carried out under certain conditions, such as in new collieries with thin seams, collieries with an ample area of unworked coal, and old collieries commencing the working of new seams with a fair roof. He went on to give his experience of electric coal-cutters, which had been a varied one, comprising failure on the one hand and success on the other. A Scott and Mountain machine was tried at the new London Colliery of the Digby Colliery Company. It was guaranteed to cut in the floor at the rate of 60 yards, 5ft. under, in nine hours. The distance cut per shift varied considerably. Sometimes the machine cut eight or ten yards, then 20 or 30, and on one occasion 70 yards, but a

Digitized by Google

portion of this length was cut in the coal, and the average distance was about 20 yards per shift. The output of coal, too, was very varied, owing to the short length of the cut and the break downs. The use of the machine was abandoned after an exhaustive trial. The author thinks that probably this failure was due to the character of the seam on which the machine was tried. The opening out of the Tupton Low Main, or furnace coal, seam at Digby Colliery suggested once more the trial of an electric coal-cutter. This seam was noted throughout the Erewash Valley for its hard holing, but its nature varied considerably. The seam was worked end-on, and the dip of the face, which was practically the dip of the seam, was 1 in 9. The holing was so hard and compact that six out of every ten men who were sent into the district as holers would refuse to work a second shift, and frequently holers failed to complete one stint—6ft. long by 4ft. deep—per shift. The greatest length ever holed for six days of work was 18 yards 4ft. under, and this was only performed on two occasions. After careful consideration it was decided to try a specially built Hurd machine to hole in the seam. Mr. Walker stated that this machine, which has a 4ft. parallel bar, proved a remarkable success, cutting a length of 57 yards in 2¾ hours, or at the rate of 20 yards per hour, and this with a remarkable reduction in the power used. The parallel bar was undoubtedly a great success, but he thought that there were one or two ways in which it could be improved. The Hurd machine was in use in the Tupton seam now, and was doing its work efficiently.

Electrolytic Refining of Lead.—Mr. Anson G. Betts contributes a long illustrated article to the current number of *Electrochemical Industry*, in which he gives full details concerning his lead-refining process, which is among the most interesting recent achievements in electrometallurgy. The solution of the problem found by Mr. Betts is probably the first one enabling the electrolytic process to enter into successful commercial competition with the older metallurgical methods, and the fact that the electrolytic process furnishes lead completely free of bismuth appears to be the main argument in favour of its success. An incidental advantage, which, however, is equally important, is the diminution of the danger of lead-poisoning to which the workmen are exposed. The novel feature of the process is the electrolyte, which is a solution of lead-fluosilicate, containing an excess of fluosilicic acid. It is easily prepared from inexpensive materials; it may be made to contain a considerable amount of dissolved lead; it conducts the current well, is easily handled and stored, and is non-volatile and stable under electrolysis. Mr. Betts states that the electrolyte takes up no impurities, except possibly a small part of iron or zinc. On the basis of a content of 0·01 per cent. of zinc and soluble iron in the anodes, and on the basis of 150 cubic feet of solution required for every ton of lead turned out per day by the refinery, Mr. Betts estimates that in one year the 150 cubic feet will have taken up 93lb. of iron and zinc, or about 1 per cent. These impurities can accumulate to a much greater extent than this before they become objectionable. Mr. Betts also points out that the electrolyte may be easily purified in several ways. An interesting detail of importance is the simple method by which a dense, coherent, and solid cathodic deposit of lead is obtained. The lead "trees" produced under ordinary conditions are well known. When the Betts process was first operated with the pure fluosilicate solution containing an excess of fluosilicic acid the lead grew from the cathode towards the anode, and in order to avoid short-circuits it became necessary to periodically remove the cathode and roll down the lead. This difficulty was overcome by the addition of some gelatine or glue in small quantities to the electrolyte. With this addition to the solution a dense deposit of lead is obtained, its density being greater than can be produced by rolling the crystalline deposit unless great pressure is used. Commenting editorially on the Betts method, our contemporary expresses the hope that the success thus obtained in the electrolysis of lead, generally accepted as impracticable, may give some encouragement to the employment of similar methods in the treatment of some other metals. This hope appears justified, especially in view of the fact that in the Betts process it has been found to be possible to obviate the chief difficulty—spongy deposits—by inexpensive means.

The Future of the Telephone.—Under this heading Mr. F. E. Bains, one time a prominent official in the Government Post Office service, writes a long letter to the *Times*, which is published in last Monday's issue. Taking as his text the acquisition last year by the National Telephone Company of the Tunbridge Wells municipal undertaking, Mr. Bains, who is himself a resident in that district, enters a protest against the manner in which the telephone system in Tunbridge Wells is conducted. His own personal experience has been anything but encouraging. Four months ago he formally applied to the company for a telephone service to the borough exchange, but so far no notice whatever has been taken of his application. The writer hits upon this treatment of an individual as an excuse for raising the question of the renewal of the company's license now approaching expiration, and, in short, advocates the telephone service being in the hands of the Post Office Department. Surely, he demands, it is time that a definite policy, of which the public at large could really approve, should at last be laid down for regulating the development of "that simple but mighty engine of public convenience and social order, the telephone." It has never yet had a fair chance in the 30 years of its young life. Such a policy he outlines thus: (*a*) The telephones, with a single but substantial reservation, to be constructed and worked exclusively by the Postmaster-General, under the terms of his legal monopoly; (*b*) on the expiration of the licenses to the National Telephone Company, such of the plant as may be suitable to be acquired by the Post Office at a valuation; (*c*) all incorporated towns not already equipped to be supplied with a telephone service by the Post Office, just as that office supplies them with telegraphic accommodation; (*d*) all other towns, and even considerable villages, to be similarly equipped, so far as an annual vote of Parliament allows, preference being given to such as guarantee from the rates actual working expenses; (*e*) the reservation to be that such cities and towns as have already (under license) constructed systems of their own with possibly extensions into a rural area defined, or at least agreed to, by the Postmaster-General to be confirmed in their equities, and other towns prepared to construct local systems to be licensed to do so. Probably there should be a reduction of the royalty now payable to a lower percentage, and certainly a substantially cheapened and, for local services, uniform tariff fixed by the Legislature would be a public boon. In touching on a further point, the writer admits having no exact data to go upon, but his impression is that to the public—in the main, in fact, to all users of the telephone, wholesale traders excepted—local services, which are usually swift and certain, are greatly more in request than those over long distances, which in many cases have been found to be uncertain and slow. If so, this is an argument for the rapid and effective establishment of municipal systems.

SOME NOTES ON THE DESIGN OF MAGNET SYSTEMS FOR CONTINUOUS-CURRENT MACHINES.

BY T. SQUARE.

(Concluded from page 396.)

Yokes.—Cast-iron yokes are to be preferred to cast-steel (except in cases where weight is a great disadvantage), for the following reasons: (1) Owing to the greater elasticity of cast steel, it takes up mechanical vibrations much quicker than cast iron, especially as it is only about one-half the section. These mechanical vibrations will aggravate any tendency to "buck" if such be present. (2) Cast iron being of twice the section, there will be a greater amount of eddy currents set up in it, tending to resist any change of flux, so making a more "stable" machine, especially on low fluxes. (3) Cast steel when obtained is rather uncertain in its magnetic qualities, and also very liable to large blowholes, especially in large castings. This is a very serious defect, and one which is practically absent in cast iron. These blowholes, unless they happen to be broken into during machining, often entirely escape observation until the machine has been completed and is about to be tested. We then find that it cannot be made to give its correct voltage, or that one pole is much stronger than another, etc., the only cure being to drill a series of test holes and fill up any cavities so found by means of "thermite" or some other similar mixture. (4) The cost of a cast-steel yoke is more than that of a cast-iron one, and the time required for delivery, more especially for large castings, is considerably longer, it being much more difficult to make. For these reasons most of the principal firms are now adopting the cast-iron yoke, which they can cast at their own foundry.

Most old multipolar machines used to have a *metal spool* on which the field winding was wound, and which served to keep each wire in its place. Many engineers also thought that this metal sheet encircling the pole acted somewhat as a Hutin and Leblanc amortisseur, large eddy currents being set up in it whenever the flux in the pole changed, the effect of these eddy currents being, of course, to oppose the change. This is a very useful effect, and no doubt exists to some extent, but from experiments which the writer has made it does not appear that this effect is very large. At any rate, these spools have been dispensed with on many modern machines, it being found that when the field coil had been soaked in insulating compound and dried in the vacuum oven, and finally whipped round with string and tape, the winding was quite stiff enough to withstand any knocking about it was liable to receive. On doing away with these spools also it was found that the bobbins ran cooler, and might have, of course, a slightly shorter length of mean turn.

Calculation of the Maximum Ampere-Turns per Pole Required.—In order to determine this we must first draw the open-circuit magnetisation curve of the machine, which gives us the ampere-turns required for any given flux when the machine is running on no load. The method of doing this is described fully in many text-books, and need not be entered into here. In order to find the maximum ampere-turns required on full load, we must add to the no-load value a certain number to balance the extra flux density in the air-gap and teeth on load caused by the cross-magnetising ampere-turns of the armature distorting the flux, as shown in Fig. 1. We must also add sufficient to balance the demagnetising ampere-turns of the armature if the brushes are not placed at the neutral position. As the demagnetising ampere-turns are in direct opposition to the main field, we must just add to the main field the same number of ampere-turns in order to keep the flux constant. This number is easily calculated. Let the total number of armature conductors be N, and the current in each conductor on full load be C, then

$$\frac{N\,C}{2\,p} = \text{ampere-turns per pole on armature,}$$

and if $\rho = \dfrac{\text{displacement of brushes from neutral position}}{\text{pole-pitch}}$, then

$$\frac{\rho\,N\,C}{2\,p} = \text{demagnetising ampere-turns per pole of armature.}$$

Again, if the armature is that of a large multipolar machine, with parallel or lap winding, we must also make some allowance for the circulating currents, which will undoubtedly exist owing to unavoidable small differences in the magnetic circuits, no matter how carefully the machine is balanced. If equalising rings are fitted (as is done in most modern machines to obviate the sparking caused by these circulating currents passing through the brushes, by offering a path of lower resistance), these circulating currents will naturally be of even greater dimensions than before. They increase both the demagnetising and cross-magnetising effect of the armature, but owing to the fact that they sometimes oppose the main current instead of increasing it, their effect is not so great as might be imagined. In a well-designed machine their demagnetising effect should not be more than from 6 to 12 per cent. of the armature ampere-turns per pole.

Supposing we have determined the flux we require on full load to give the machine the correct voltage at its terminals, taking into account the C R drop of the armature and brushes. Then we have from above:

A.T. per pole on full load = A.T. to give full load flux on open circuit + A.T. required for cross-magnetising + A.T. required for demagnetising + A.T. allowed to balance the effect of circulating currents.

In addition to all this, it is usual to allow a margin of from 5 to 20 per cent. more, in case the iron should not be of good quality, or the steel contains blowholes. If the machine is *shunt wound*, we should then take the maximum ampere-turns per pole as found from the above considerations, and make a first preliminary shot at the section of winding required by taking 90 to 60 ampere-turns to each square centimetre of winding section for 70deg. F. final temperature rise. The depth of winding of a coil should not exceed 6cm. to 8cm. on any machines, as a coil with a greater winding depth than this does not get rid of its heat so readily, and hence, in order to obtain a certain number of ampere-turns, we have to use a greater weight of copper. In fact, the smaller the winding depth the more efficiently is the copper used, for it not only gets rid of its heat more quickly, owing to its larger radiating surface, but also, owing to its small winding depth, the length of the mean turn of winding is smaller, and hence the watts wasted are less. We must, however, not carry this too far, as the increased length of pole required increases the size and cost of the magnetic system. The best depth of winding in any case is, of course, that in which the saving in copper obtained by still further reducing the depth of winding is just equal to the extra cost of the magnetic system. Dividing the approximate cross-section of winding obtained as above by the winding depth we have selected, we obtain the length of field coil parallel to its axis.

The ampere-turns of a shunt coil with a given voltage across its terminals depends only on the diameter of the bare wire and the length of mean turn—*i.e.*, the mean resistance of a turn. If we had only one turn, we should still get the same ampere-turns, provided we could keep the copper at the same temperature. But this would waste much more watts than a many-turn coil, and would not have nearly so much cooling surface to get rid of the heat; hence the wire would, in practice, be burnt up almost at once. In other words, the ampere-turns a coil will give depends only on the bare diameter of the wire and the length of mean turn, but the more turns we put on the less the watts wasted, and hence the more efficiently do we produce those ampere-turns; hence the cooler the bobbin will run, especially as the cooling surface is increasing with the number of turns. This can easily be seen.

Suppose we have one turn of wire of one ohm resistance with one volt across its terminals. Then the current flowing $= \dfrac{E}{R} = \dfrac{1}{1} = 1$, and ampere-turns $= 1 \times 1 = 1$ and $C^2\,R$ watts $= 1^2 \times 1 = 1$.

Now take two turns: resistance = two ohms, with still one volt across; current flowing = $\frac{1}{2}$, and ampere-turns $= \frac{1}{2} \times 2 = 1$ and $C^2\,R = (\frac{1}{2})^2 \times 2 = \frac{1}{2}$.

Or with 10 turns, resistance 10 ohms: current flow-

Digitized by Google

ing $= \frac{1}{10}$; ampere-turns $= \frac{1}{10} \times 10 = 1$; and $C^2 R$ watts $= (\frac{1}{10})^2 \times 10 = \frac{1}{10}$. We thus see that by increasing the turns from 1 to 10, while the ampere-turns have kept the same, the watts wasted have gone down in the ratio of 10 to 1. So that, in determining the best winding cross-section, we should balance the extra cost of copper against the saving in excitation watts which it effects, keeping within the specified temperature rise.

Let R = cold resistance per bobbin;
R × 1·15 = hot resistance per bobbin;
E = volts per bobbin—*i.e.*, $\frac{\text{volts of machine}}{\text{No. of poles}}$;
C = shunt current in amperes;
D = winding depth of coil in centimetres;
L = axial length of coil in centimetres;
D × L = gross winding cross-section in square centimetres;
D × L × S = net winding cross-section after allowing for slack and all insulation except that around the wires themselves (S is usually about ·7);
d = insulated diameter of wire in millimetres;
d_1 = bare diameter of wire in millimetres;
l = length of mean turn in centimetres;
σ = resistance of wire 1cm. long of diameter d_1;
W = permissible watts wasted per coil for specified temperature rise.

The length of mean turn and length of outside turn can be calculated from the following formulæ:

For Rectangular Poles (see Fig. 8)—

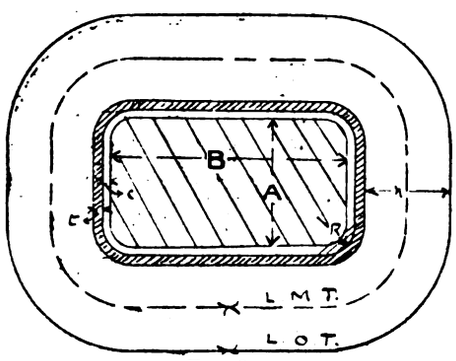

Fig. 8.

L.M.T. cm. = 2 A + 2 B + 8 c + 2 π t + π n − 1·717 R.
L.O.T. cm. = 2 A + 2 B + 8 c + 2 π t + 2 π n − 1·717 R.

For Round Poles (see Fig. 9)—

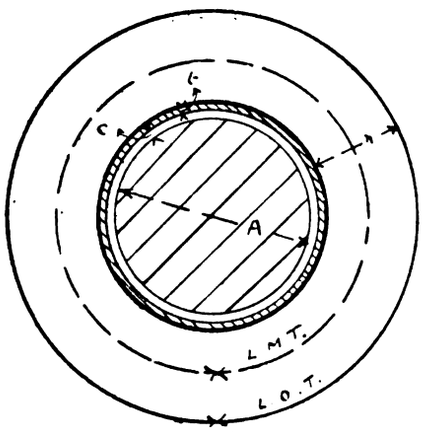

Fig. 9.

L.M.T. cm. = π (A + 2 c + 2 t + n).
L.O.T. cm. = π (A + 2 c + 2 t + 2 n),

where A and B = dimensions of pole limb in centimetres;
c = clearance between bobbin and pole limb in centimetres;
t = thickness of spool in centimetres, if any;
n = winding depth in centimetres;
R = radius to inside of spool at corner, if bobbin edges are rounded off.

The radiating surface is usually taken as the outside peripheral surface only, which is in contact with the air. It has been found from experience, that if the ratio $\frac{\text{axial length of coil}}{\text{winding depth}}$ is greater than 1·5, we can waste, taking this radiating surface, ·1 watt per square centimetre when the armature has a peripheral speed of 5m. per second; ·12 watt per square centimetre for a speed of 20m. per second. Hence we can at once work out the permissible watts, W, the radiating surface being the product of the length of outside turn of the winding and its axial length.

Now, considering one turn, we have:

Ampere-turns per coil when hot = current × turns

$$= \frac{E}{\text{Resistance} \times 1{\cdot}15} \times 1.$$

Resistance per turn

$$= \frac{(\text{Resistance of wire 1 sq. mm. section and 1em. long}) \times l}{\text{Section of wire in sq. mm.}}$$

$$= \frac{{\cdot}00017 \times l}{{\cdot}7854\, d_1^2} = \frac{l}{4{,}620 d_1^2}.$$

$$\therefore \text{ ampere-turns per coil hot} = \frac{E \times 4{,}620\, d_1^2}{l \times 1{\cdot}15};$$

or,

$$d_1 = \sqrt{\frac{\text{ampere-turns} \times l}{E \times 4{,}000}}.$$

From this formula we get the bare diameter of wire required, and knowing the thickness of insulation on the wire, we can also find the insulated diameter, d.

Now,

$$\text{turns} = \frac{D \times L \times S \times 100}{{\cdot}7854\, d^2},$$

and hence

$$\text{Resistance of coil cold} = \frac{l}{4{,}620\, d_1^2} \times \frac{D \times L \times S \times 100}{{\cdot}7854\, d^2}$$

and watts wasted per coil hot

$$= \frac{E^2}{R} = \frac{E^2 \times 4{,}620 \times d^2 d_1^2}{D \times L \times S \times l \times 127 \times 1{\cdot}15}$$

$$= \frac{E^2 \times 31{\cdot}7}{D \times L \times S \times l}.$$

If this figure is less than the permissible watts, W, we know that the temperature rise will be less than the specified in the same proportion. If the temperature rise is too high, we must alter L or D and l until we obtain a satisfactory figure.

It is sometimes required to work out the converse problem to this—*i.e.*, to find the maximum ampere-turns which can be obtained from a given winding section. We then proceed as follows:

Watts wasted = C E and $C = \frac{E}{R}$

$$\therefore \text{ watts wasted with coil hot} = \frac{E^2}{R \times 1{\cdot}15}$$

$\therefore$ minimum cold resistance of coil in order for it not to overheat $= \frac{E^2}{W \times 1{\cdot}15}$

$$\text{But cold resistance} = \frac{l}{4{,}620\, d_1^2} \times \frac{D \times L \times S \times 127}{d^2}$$

$$\therefore \text{ equating } d^2 d_1^2 = \frac{W \times l \times D \times L \times S \times 127 \times 1{\cdot}15}{E^2 \times 4{,}620}$$

or,

$$d\, d_1 = \sqrt{\frac{W \times l \times D \times L \times S}{E^2 \times 31{\cdot}7}}$$

All we have to do, therefore, is to find two diameters whose product is equal to the expression on the right, and whose difference is equal to the increase of diameter due to insulating the wire. The following table gives the thickness of double cotton covering adopted by a large firm of wire manufacturers in London:

Wire up to 1mm. in diameter, add ·2mm.
Over 1mm. and up to 1·5mm., add ·3mm.
Over 1·5mm and up to 2mm., add ·4mm.
Above 2mm., add ·5mm.

From this table it will be seen that the thickness of insulation is increased with the size of wire. This is because the larger wires, being stiffer, are more likely to

Digitized by Google

damage their insulation in the process of winding than the thin wires. It will easily be seen that if the grading is carried out systematically—*i.e.*, the ratio $\frac{\text{diameter of wire bare}}{\text{diameter of wire insulated}}$ is always roughly constant—then the weight of wire which we can get into a given space is also roughly independent of the diameter of the wire. Having determined d and d_1, we have

Maximum ampere-turns

$$= \frac{E}{R} \times \text{turns}$$

$$= \frac{E}{1{\cdot}15 \times R} + \frac{D \times L \times S \times 127}{d^2}$$

$$= \frac{E \times D \times L \times S \times 110{\cdot}5}{R \times d^2}.$$

Compound Machines.—By means of a suitable series coil we can make the difference between the volts at no load and full load vary as we like over a fairly large range. We work out the ampere-turns required at no load and full load, and then design the shunt coil to give at no load the required no-load ampere-turns. Next work out the ampere-turns of the shunt coil at full load and subtract this figure from the full-load ampere-turns required. The difference is the series ampere-turns.

The series coils on each pole are best connected in series, for if they are connected in parallel the resistance of one coil may be slightly different from another (very probably owing to a difference in the joint contacts), and the ampere-turns per pole would consequently be unevenly divided, tending to set up circulating currents, etc. This effect is, however, self-corrective to some extent, as the coil with the higher current reaches a higher temperature, which increases its resistance and so tends to reduce the current to its proper value. If the series coils are connected in series, practically the whole main current of the machine flows through each coil. This means that as the current density can rarely be allowed to exceed 1·1 amperes per square millimetre, the cross-section of copper per effective turn is rather large. For ease of manufacture, in order to make these turns easy to wind, they are made up of a great number of laminations, ·5mm. to 1·0mm. thick, all in parallel. This makes the connections between coil and coil rather bulky, and in order to have plenty of room for these, it is a good thing to place the series coil next the yoke.

The writer in these few notes has not attempted to give anything like a full description of all the considerations entering into the design of magnet systems, but has merely put forward a few points in connection with the subject which may be of interest to those engaged in designing work.

PROTECTIVE DEVICES FOR HIGH-TENSION ELECTRICAL SYSTEMS.*

BY W. B. WOODHOUSE, A.M.I.MECH.E., A.M.INST.E.E.

The extending use of high-tension polyphase transmission is resulting in a gradual standardisation of the methods adopted to protect such systems against breakdown, but there is still some considerable diversity of opinion shown. The writer proposes to discuss several points in connection with the operation of a high-tension polyphase transmission system.

Nature of System.—Power is supplied to sub-stations through underground cables; in the sub-stations the converting machinery may consist of static transformers, motor-generators, and rotary converters. The economical voltage of transmission is decided by the cost of cables; above 10,000 volts, step-up transformers are needed at the generating end, but in such schemes as are working or projected in this country 10,000 volts is the higher limit. The design of the system should be such that each part of the system is automatically disconnected in the event of a breakdown of that part; the continuity of supply being of primary importance, all parts should be duplicated. The duplication of feeders to each sub-station does not involve excessive expenditure when the generating station is at the centre of the area of supply, as in Fig. 1, wherein two feeders are shown running from the generating to each sub-station; where this is not so, as when a number of sub-stations are closely grouped, such an arrangement becomes too costly, and interconnecting cables must be run between the sub-stations to provide alternative ways of supply. Fig. 2 shows such an arrangement, which is the case more frequently met with. In the first arrangement, power always flows in the same direction along any cable; in the second, power may be required to be transmitted in either direction on any interconnector.

Stresses on the System.—In switching on an unloaded cable a wave of pressure passes along the cable and is reflected; there may be a rise of pressure to twice the working value. In switching on a transformer or an induction motor, or any apparatus with considerable inductance, the full pressure exists for the moment between adjacent coils, the greatest stress falling on the end coils. An inductive circuit has stored energy to the amount of $\frac{I^2 L}{2}$ joules, which must be dissipated when the circuit is broken. In a transmission system, such as is considered, this energy may be converted to the electrostatic form on opening circuit with a resultant rise of pressure; neglecting damping effects, the pressure may rise to a value of $E = I\sqrt{\frac{L}{C}}$, or the rise of pressure is proportional to the current flowing at the moment of interruption. Pressure rise from resonance is not likely to occur in commercial systems in this country.

Protective devices may be divided into two classes: (1) circuit breakers; (2) devices which prevent or relieve excessive rises of pressure.

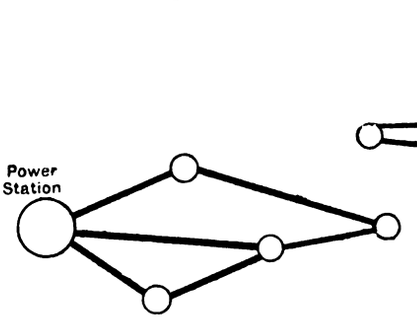

FIG. 2.

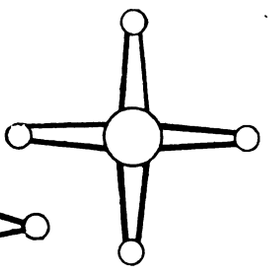

FIG. 1.

Circuit breakers are required to operate automatically (*a*) on an overload; (*b*) on a reversal of the direction in which power is flowing. The overload device should be fitted to every circuit breaker; the use of the "return current" relay is limited to generator switches and those at the sub-station ends of feeders; should one of a number of generators break down, power will flow from the sound machines to the faulty one when the switch automatically opens. In a feeder system as in Fig 1, should one of a pair of feeders break down, power will flow into the fault from both ends, the reverse current relay disconnects the sub-station end, and the overload relay the power station end. In such a system as is shown in Fig. 2, it is obvious that the interconnecting cables can only be protected by overload relays. The interval of time between the occurrence of an overload and the opening of the circuit should be inversely proportional to the magnitude of the overload, that is to say, on a moderate overload there should be a time-lag of some seconds. A little consideration will show that all circuit breakers on a system should be capable of breaking the whole power which can flow into that part of the system.

Fuses.—The use of fuses as circuit breakers on high-tension systems has followed from low-tension practice. There are two main types in common use: the one in which strips of fusible metal, 10in. or 12in long, are enclosed in a porcelain or glass tube, the arc being blown out by the heated air; the other type in which the fuse is a short wire or wires, $\frac{1}{2}$in. to $\frac{3}{4}$in. long, held in tension by springs over a pot of oil, the arc being quenched by the withdrawal of the contacts into the oil. In the first type, which finds extensive use on the Continent, the fuse strips are made of tin, aluminium, or silver. Tin is most commonly used, but aluminium has been used because its high specific heat has advantages where a large time-lag is required. The results of tests on these types

* Paper read before the British Association.

of fuses are shown in Fig. 3, in which the time taken for a fuse to blow after the application of a definite overload is marked as a point on a curve. It will be seen that the

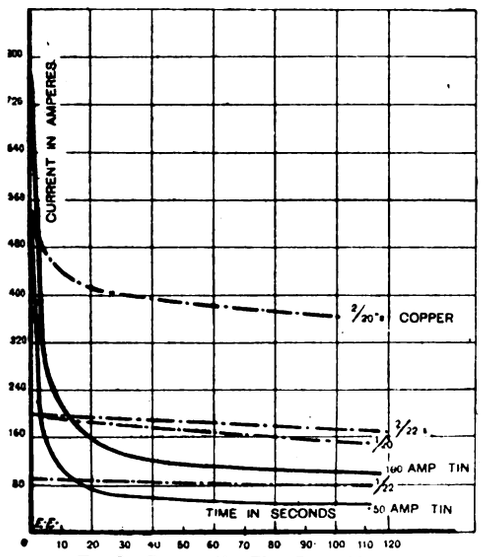

FIG 3.—Comparative Time Lags of Fuses.

second, the Ferranti type of fuse, blows almost immediately the current reaches the fusing value, whatever be the magnitude of the overload, but the long fuse takes many seconds to blow on a moderate overload, and an appreciable time even on a heavy overload; or, one has practically no time-lag, and the other has too much on heavy overloads. In the design of fuse receptacles, it must be remembered that in opening a circuit power is absorbed by the resistance of the fuse. In an inductive circuit the maximum power put into the fuse (a non-inductive receiving circuit) occurs when the resistance of the fuse is equal to the impedance of the remainder of the system, and is $\frac{k^2}{2(r+z)}$. For the same power flowing under normal conditions, the power delivered

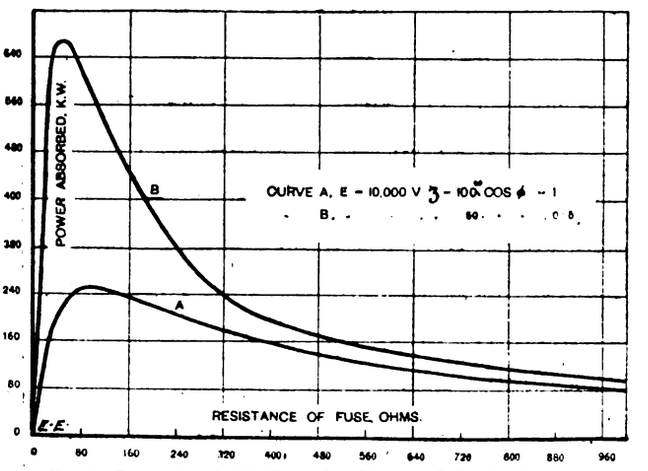

FIG. 4.—Power Absorbed in Fuse when Blown on Inductive Circuit.

to the fuse increases with a decrease of the power factor. Practical experience fully confirms this, and a fuse which takes some seconds to blow will absorb a considerable amount of energy. The exact rate of variation of the resistance of the fuse is a matter of conjecture, but Fig. 4 shows curves plotted on the assumption of a uniform increase of resistance for two cases: 1,000 kw. at 10,000 volts cos $\phi = 1$; 1,000 kw. at 10,000 volts cos $\phi = 0{\cdot}5$. The inheritance of fuses from

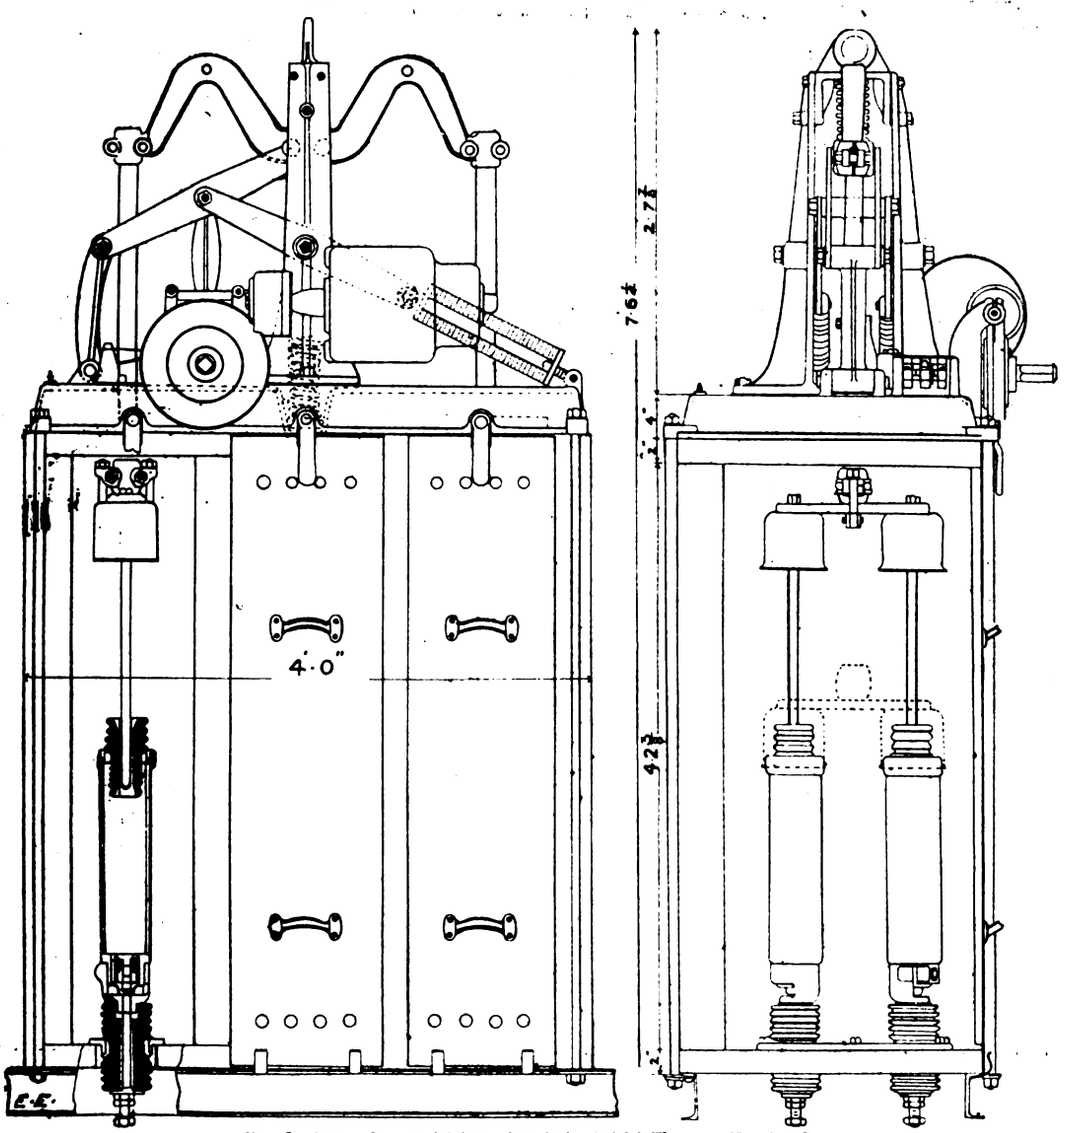

FIG. 5.—Motor-Operated Oil-Break Switch—British Thomson-Houston Co.

Digitized by Google

low-tension working has not been an unmixed blessing; they become unreliable with age, and as a switch is necessary wherever a fuse is placed, it is becoming increasingly the practice to attach an automatic relay to the switch and

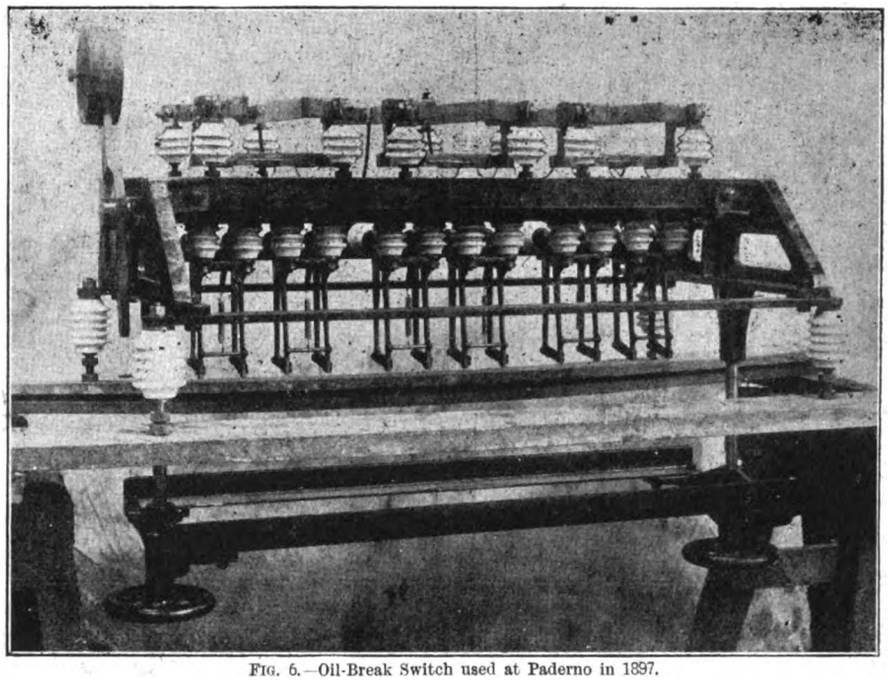

FIG. 6.—Oil-Break Switch used at Paderno in 1897.

dispense with the fuse altogether. Potential transformers for operating instruments may be excepted from the above; the breakdown of such transformers is of rare occurrence, and they are usually protected by fuses of the tube type.

Switches.—It may be laid down as an axiom that any part of a high-tension system which allows an arc to play in air is bad, on account of the dangerous pressure rises which may be occasioned. Air-break or "flare" switches are hence to be avoided. Although a time-lag is advisable on circuit breakers, yet the circuit should be opened rapidly

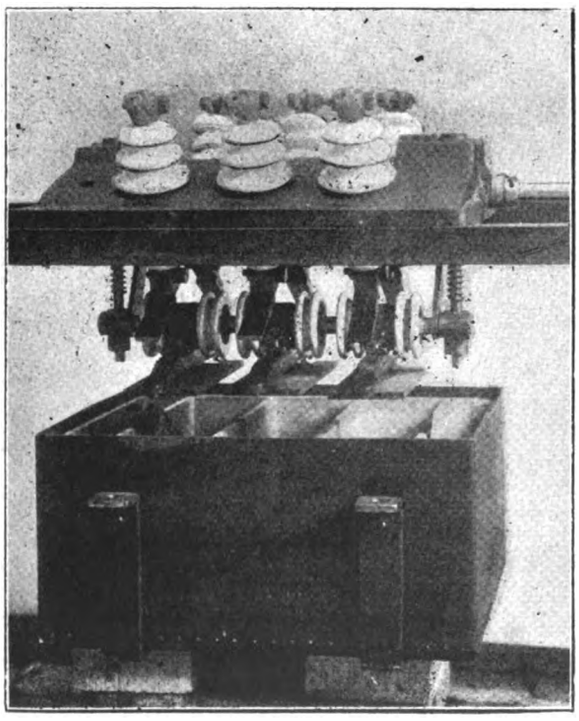

FIG. 7.—Brown-Boveri Oil-Break Switch as used at Newcastle.

when once the operation starts; it is yet more important that the opening should take place when the current passes through its zero value.* The results of many experiments seem to show that an oil-break switch does break circuit at the moment of zero current, and for this reason such switches are now generally adopted. The switchgear is so designed that each switch is in a separate fireproof chamber of metal, brick, slate, or concrete. For safety the switches, 'bus bars, etc., are placed some distance from the operator, the switches being operated by links and levers, chains, pneumatically, or electrically. In a large board the operation by means of electrical motors is the most convenient, as the "control board" may be made quite small. Control by means of direct-current motors find most favour, as the direct current is used also in the actuation of the relays, and may be supplied from a storage battery which is used for exciting. There should be no possibility of an arc

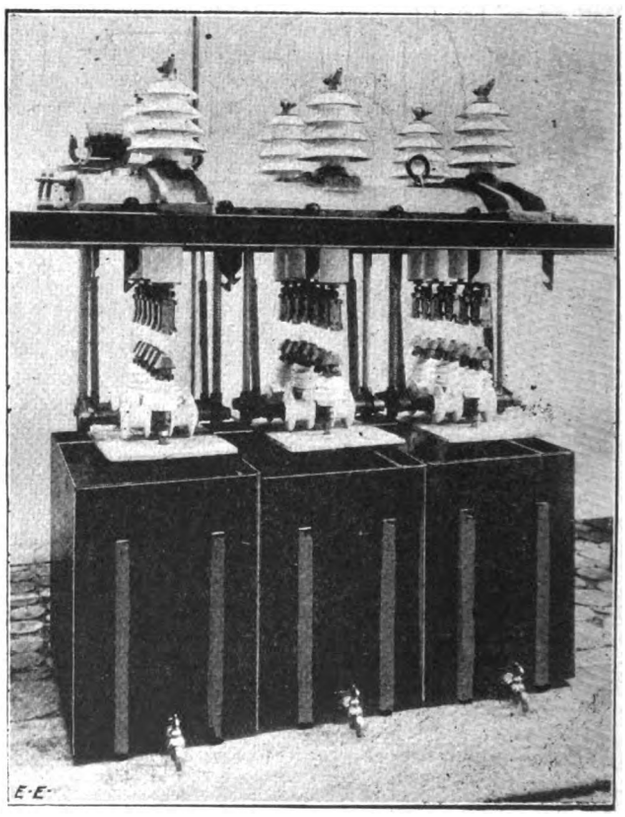

FIG. 8.—Oil-Break Switch for 40,000 volts, with Overload Release—Brown, Boveri, and Co.

on one phase of a switch passing to another phase, or to any other metal work. In switches for large currents, contacts external to the oil are sometimes fitted so that there shall be no danger from heating of a contact in the oil; these external contacts do not make or break circuit, but are in parallel with the oil-break contacts when the switch is closed. Fig. 5 is a typical example of an oil-break switch for heavy work

Digitized by Google

made by the British Thomson-Houston Company. The switch is operated by a direct-current motor seen at the top. Circuit is made or broken on each pole in two cylindrical oil vessels containing the contacts, the top contacts consisting of two rods yoked together and sliding through insulators. All the live metal parts are in compartments made of brick and soapstone slabs, connection to the operating gear being made by wooden rods. The motor works a crank through a worm gear. When the crank is on a dead centre, a spring is compressed ready to operate the switch; the slightest movement of the motor causes the spring to come into play, at the same moment a friction clutch releases the motor from the gear, the motor continues running until it has compressed the spring ready for the next operation, when an automatic switch opens the motor circuit and lights a lamp to indicate that the switch has acted. The motor is controlled by a double-throw hand switch; the automatic overload or return current relays operate by closing the motor circuit. The first oil-break switch to be put into practical use was at the Paderno power station in 1897. This was designed by Messrs. Brown, Boveri, and Co. for three-phase currents at 16,000 volts. Fig. 6 shows the general arrangement of this switch, with the oil-chamber removed. Fig. 7 shows a hand-operated switch, of which a large number are in use on the system of the Newcastle Electric Supply Company. There is one oil-chamber for the three phases, but a wooden lining partitions the chamber into three. There are six fixed

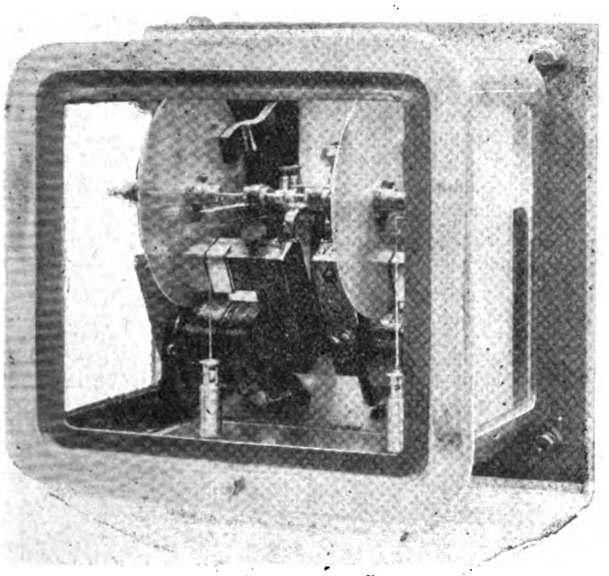

FIG. 9.—Overload Relay, with Adjustable Time Lag.

contacts, and three copper bridging pieces which are moved vertically to make or break circuit. Underneath each pair of contacts will be noticed a small board which moves up and down with the bridging pieces and churns the oil at the moment of make or break, thus minimising the danger from carbonisation of the oil. The writer has tested this type of switch severely at 6,000 volts and found it in every way satisfactory. A similar type of three-phase switch, also made by Messrs. Brown-Boveri, but for a higher voltage, is shown in Fig. 8. The oil-chambers are lowered down showing a six-fold break on each pole; the design of the insulators is especially good. To the left hand of the cover will be noticed the automatic tripping device which opens the switch in connection with an overload relay; the switch is closed by hand.

Overload Relays.—These are usually worked by series transformers in each phase, the secondary current passing through a solenoid, which actuates the tripping device A representative device for obtaining a time-lag in operation is as follows (Fig. 9): The secondary current of the series transformer passes round the windings of a magnet, between the poles of which is a copper disc capable of rotating; on the same spindle as this disc is a small drum to which a weight is connected by a fine cord. Normally the disc is stationary, the tendency to rotate being balanced by the moment of the weight; on an overload, the disc rotates and winds up the weight, which closes an auxiliary circuit and thus opens the main switch. The rate of rotation is proportional to the current flowing in the main circuit, and the time-lag may be adjusted by altering the length of the cord. Such an arrangement is very sensitive and works well.

Reverse-Current Relays.—Such devices are actuated by the secondary current of a transformer having two or more primary windings—one in series with a line, the other across two lines. Under normal condition the fluxes produced by these windings are in opposition, that of the potential coil being the stronger, but when the power flows in the reverse direction a current is generated in the secondary circuit which works the relay. Should a generator break down, in the majority of cases the current passing will be the short-circuit current of the machine (great enough to work an overload relay), but at the same time the pressure across the terminals of the alternator (and the transformer) may fall to zero, and the relay not act. For these reasons return-current indicators find more favour than relays; the indicator, usually a coloured lamp, shows which part of the system is at fault, and the switch is operated by the attendant. A very neat reverse-current indicator is that of Mr. Andrews's, described in his paper before the Institution of Electrical Engineers in March, 1903.

Devices which Prevent or Relieve Excessive Pressure Rise.—The causes of pressure rise in a system are set out above. Any device which only acts on the switching on or off of a cable is a partial safeguard, which should not be used if a complete safeguard can be found. For such a purpose as the above, series resistances (liquid) and choking coils have been used and in many cases afterwards discarded. Spark gaps which remain always connected across the cores of each cable meet every rise of pressure, from whatever cause, but

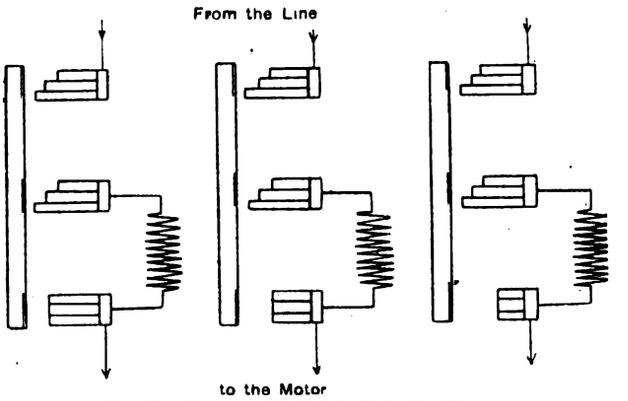

FIG. 10.—Diagram of Switch for Induction Motor.

have disadvantages. The most sensitive spark gap consists of needle points in air, the disruptive voltage being almost independent of humidity and dust, but the passage of a small spark will destroy the points. The horn arrester in which the arc is struck across the lower extremities and rises until it breaks has found extensive use. The Wurts arrester has a number of brass cylinders with knurled or smooth surfaces placed with their axes parallel and with equal gaps between them. In this type the nature and mass of the metal chills the arc which may be formed. A modification of the above consists of two concentric cylinders, the ends of the outer cylinder having conical additions. The arc is chilled as in the Wurts, and blows itself out as in the Siemens type. Series resistances are occasionally used with the idea of minimising the rush of line current which may follow a discharge. The writer has found the Wurts type to be fairly reliable, but when dealing with large rises of pressure and large powers, the discharge localises on the cylinders and forms blisters, sometimes fusing the rollers together. In all the above an arc in air may form with consequent danger to the system, and for this reason the writer has tried the effect of immersing spark gaps in oil. The disruptive strength of some mineral oils is about equal to that of air, so that the distance between the gaps need not be made smaller. The gaps are protected from dust and moisture, and the sparking distance remains constant. The arc is extinguished in the oil as in the oil-break switch, and it is reasonable to suppose that it is extinguished at the instant of zero current. On the disturbance of a system due to a sudden change of current flowing, these gaps must be capable of absorbing a considerable amount of energy, the energy of the surge,

Digitized by Google

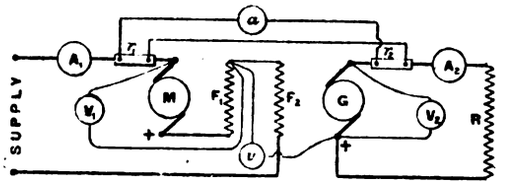
and are therefore liberally proportioned. To test the oil-immersed spark gaps, the following experiments were made. The oil-gaps were set to discharge at 8,000 volts on an inductive circuit and shunted by a pair of needle points set to discharge at 10,000 volts. On the application of 8,000 volts the gaps worked, the arc being extinguished in the oil; the applied voltage was gradually raised to 10,000, but the oil-gaps worked in every case: the needle points never came into action. The test was then repeated with both sets of gaps in air, when the needle points sometimes acted before the horns.

Switching Inductive Apparatus.—On switching on a transformer or induction motor, the full pressure may momentarily exist between adjacent end coils with consequent breakdown; this abnormal stress may be minimised by switching on slowly through a resistance. As an example Fig. 10 shows the arrangement of a switch for use with a three-phase high-tension induction motor. The switch has three extra terminals connected to water resistances; on switching on, these resistances are first put in series with the windings of the motor, then short-circuited, and lastly cut out; on switching off, the reverse operation takes place.

A METHOD FOR FINDING THE EFFICIENCY OF SERIES MOTORS.*

BY ERNEST WILSON, PROFESSOR OF ELECTRICAL ENGINEERING, KING'S COLLEGE, LONDON.

The following method has the advantage of great accuracy, and I have found it work well in practice. The figure gives a diagram of connections, in which M and G are two like machines mechanically coupled together, either through or without gearing, according as it is desired to obtain the efficiency of either machine inclusive or exclusive of gearing. In the test M runs as a motor and delivers its energy to G running as a generator.



The field coils, F_1 F_2, are placed in series with one another and with the motor armature in order that each machine may be conveniently magnetised to the same degree in any test. The input of the motor is measured on the voltmeter V_1 and ammeter A_1. The generator is loaded on a resistance, R, and its output measured on the voltmeter V_2 and the ammeter A_2. Let R_1 and R_2 be the ohmic resistances of the motor and generator armatures respectively, then $V_1 A_1 - V_2 A_2 = X$ are the total watts dissipated in the system, exclusive of the generator field coil F_2. Of these $A_1^2 (F_1 + R_1) + A_2^2 R_2 = Y$ are the ohmic resistance losses in watts, and $X - Y$ are the watts due to brush, bearing, and wind friction, eddy currents, and magnetic hysteresis. The machines are equal, and rotate at the same speed. $\frac{X - Y}{2}$ are the watts which can be debited to each machine when calculating efficiency, it being assumed that the brush contact resistance has the same value as when measured with the machines at rest, and that armature reaction does not produce inequality in the watts dissipated by eddy currents and magnetic hysteresis in the two machines. The expressions for the efficiencies are, for the motor, $\frac{X - Y}{2} + V_2 A_2 + A_2^2 R_2 / V_1 A_1$, and, for the generator, $V_2 A_2 / \frac{X - Y}{2} + A_2^2 R_2 + A_1^2 F_2 + V_2 A_2$

The above, so far, is a well-known method, and has been described by Mr. Field. The extension here described consists in the addition of two low-resistance shunts, r_1 r_2, a milli-voltmeter, a, and a voltmeter, v. By these instruments the differences $A_1 - A_2$ and $V_1 - V_2$ have been measured as direct quantities. It is easy to show that greater accuracy can be obtained by measuring A_1 and a and using the value $A_1 - a$ instead of A_2, and measuring V_1 and v and using the value $V_1 - v$ instead of V_2. For instance, let $V_1 = 500$, $A_1 = 50$, $V_2 = 450$, $A_2 = 42$, $R_1 = R_2 = F_1 = F_2 = 0{\cdot}5$ ohm, and let there be a liability for error of 1 per cent. in reading the instruments. Then the possible error in the value of $X - Y$, when V_1 V_2 A_1 A_2 are the measured quantities, is 31·9 per cent., whereas it is 1·9 per cent. when V_1 v A_1 a are the measured quantities.

* Paper read at the British Association, Southport, 1903.

THE BRITISH ASSOCIATION.

Address to the Mathematical and Physical Section.

BY CHARLES VERNON BOYS, F.R.S., PRESIDENT OF THE SECTION.

The first duty of every occupant of this chair is a sad one. Year by year the record grows of those who have devoted their lives to the development of mathematical and physical science, of those who have completed their work. The past year has added many names to the record—more, it seems, than its fair share. The names include some of the most brilliant and active of our race, of those to whom this association is deeply indebted, and also of our fellow-workmen in other countries whose loss is no less to be deplored. Lord Salisbury's devotion to the Empire, of which this is not the occasion to speak, left him but little time for those scientific pursuits in which he took so keen an interest. Once, however, as president of this association, he showed our members that, unlike the majority of our statesmen, science was not to him a phantom. His address at Oxford will remain in the memories of all who heard it. The eloquence, the humour, the satire, the subtilty provided an intellectual treat of the rarest kind. Of Sir George Gabriel Stokes and his work it is not possible for me to speak. Any attempt on my part to appreciate or gauge the value of the work of such a giant would be an impertinence. This can only fitly be done by one of our leaders, and Lord Kelvin has paid a fitting tribute in the pages of *Nature*. I can only record the fact that Stokes was for seven years secretary and twice president of this section, and in 1869 was president of the association. Dr. Gladstone, for 53 years a member of this association, was not only an unfailing attendant at our meetings, but an active member whose steady stream of original communications on subjects connecting physics and chemistry earned for him the designation of creator of physical chemistry. His investigations on spectroscopy, refractivity, and electrolytics are known to every student of physics. His researches upon early metallurgical history, while of less importance to the progress of science, are none the less interesting. An ardent apostle of education, he was for 21 years a member of the London School Board, and three years vice-chairman. Dr. Gladstone was the first president of the Physical Society. He has been president of the Chemical Society, and at the last meeting of the British Association at Southport—as also in 1872—he was president of the Chemical Section. So long ago, he said, in urging the importance of science as a factor in education, that the so-called educated classes were not only ignorant of science, but had not arrived at the knowledge of their own ignorance. It is not possible to pass on without paying a tribute, in which all who knew Dr. Gladstone will share, to his character no less than to his genius.

Sir William Roberts-Austen was probably one of the most active members that this association has known. Not only had he for many years made the subject of metals and alloys his own, but he had worked for the association in many ways. At three meetings have audiences been charmed by his fascinating and brilliant evening lectures, all relating to metals. He was president of the Chemical Section at the Cardiff meeting in 1891, and not only did he perform these duties, but he accepted the more laborious and more thankless task, for which his unfailing courtesy and tact so well fitted him, of acting as our general secretary for four years. His labours in the important field of research which he tilled were appreciated by numerous technical societies and institutions of which he was an honorary member, or had been president or vice-president. Many branches of public service had the advantage of his skill and experience, which received the official reward in 1899. Dr. Common's skill as a designer and constructor of instruments was well known. His instinct or judgment in producing planes and figured concave mirrors of great dimensions was rare, for this is an art almost unknown in the laboratory. His generosity and his valuable advice have been appreciated by many besides myself. Rev. H. W. Watson, Second Wrangler and Smith's Prizeman in 1850, was a vice-president of the British Association in 1886. Mathematical physicists are familiar with the joint work of himself and Burbury on "Generalised Co-ordinates," and with his mathematical articles. In Otto Hilger, the brother of the late Adam Hilger, who between them brought to this

Digitized by Google

country German thoroughness and French skill in instrument manufacture, we have lost one of our first and most valuable constructors. Noted for the high class of all the optical work turned out by the firm, Otto Hilger was not afraid of attacking the problem of manufacturing the Michelson echelon grating. This little bundle of glass plates requires for its success perfection and precision commensurable only with the genius of the inventor. This Otto Hilger supplied.

Dean Farrar, a life member of the British Association, whose activity lay in another direction, showed his appreciation of the value of science in education by appointing the first science master at Marlborough when he became headmaster in the year 1870. As I was a boy at the school at that time, I can speak of the incredulity with which such an announcement was at first received, and of the general feeling that such an action was akin to a joke. I was, however, by no means the only boy who hailed the news with delight. We devoured the feast of chemistry and physics put before us by Rodwell and the books which at once became available. Out of gratitude to the late Dean of Canterbury I recall this episode. James Wimshurst, the inventor of the influence machine which has carried his name into every corner of the scientific world, was not a member of this association, but he fostered and encouraged the scientific spirit in young men who by good fortune came to know him. I do not think I have heard anyone spoken of with such gratitude and appreciation as Wimshurst by men who in their younger days were allowed the run of his well-equipped workshop. James Glaisher, best known as a balloonist in the sixties, has died at the great age of 93. The balloon ascent with Coxwell on Sept. 5, 1862, when they attained the altitude of 37,000ft., will long remain in the popular imagination, not on account simply of the great altitude, but by reason of the sensational account of their having been paralysed with cold, and of their being able to stop the ever-increasing ascent only by the presence of mind of Coxwell, who, with his limbs frozen, seized the valve rope with his teeth, and so let out the gas. While this event remains in everyone's mind, the more prosaic work of Glaisher in astronomy, meteorology, and photography, when most of us were children, and many yet unborn, led to his being elected president of various learned societies. He gave one of the evening lectures of the British Association in 1863, the subject being balloon ascents. A. F. Osler, the inventor of the self-recording direction and pressure anemometer and rain-gauge, whose active meteorological work was carried out in the first half of the last century, when he contributed papers to the British Association and the Literary and Philosophical Society of Birmingham, has died at the still greater age of 95. He was vice-president of the British Association in 1865.

Of other countries, America has lost Prof. J. Willard Gibbs, a mathematical physicist whose very learned and original contributions to the knowledge of the world on the thermodynamical properties of bodies, on vectors, the kinetic theory of gases, and other abstruse subjects, have received the highest recognition that the learned societies of this country can bestow. Prof. Harkness, the astronomer, and Prof. Rood, the skilled experimental physicist of Troy, have also maintained the high standard that we now look for in American science. Germany has lost Prof. Deichmüller, professor of astronomy at Bonn, at an early age. Sweden has lost Prof. Bjerknes, whose hydrodynamical experiments showing attraction and repulsion were so much admired when he performed them at a meeting of the Physical Society some 25 years ago. Switzerland has lost Prof. C. Dufour, the astronomer; and Italy has lost Prof. Luigi Cremona, a foreign member of this association, principal of the engineering school in Rome, whose contributions to pure geometry and to its applications have made him famous.

Of the events of the last year, one stands out beyond all others, not only for its intrinsic importance and revolutionary possibilities, but for the excitement that it has raised among the general public. The discovery by Prof. and Madame Curie of what seems to be the everlasting production of heat in easily measurable quantity by a minute amount of a radium compound is so amazing that, even now that many of us have had the opportunity of seeing with our own eyes the heated thermometer, we hardly are able to believe what we see. This, which can barely be distinguished from the discovery of perpetual motion, which it is an axiom of science to call impossible, has left every chemist and physicist in a state of bewilderment. Added to this, Sir William Crookes has devised an experiment (characteristic of him, if I may say so) in which a particle of radium keeps a screen bombarded for ever, so it seems, each collision producing a microscopic flash of light, the dancing and multitude of which forcibly compel the imagination to follow the reasoning faculties, and realise the existence of atomic tumult. Thanks to the industry and genius of J. J. Thomson, Rutherford and Soddy, Sir William and Lady Huggins, Dewar and Ramsay, and others in this country, besides Prof. and Madame Curie and a host of others abroad, this mystery is being attacked, and theories are being invented to account for the marvellous results of observation; but the theories themselves would a few years ago have seemed more wonderful and incredible than the facts, as we believe them to be, do to-day. An atom of radium can constantly produce an emanation—that is, something like a gas—which escapes and carries with it wonderful properties; but the atom, the thing which cannot be divided, remains, and retains its weight. The emanation is truly wonderful. It is self-luminous; it is condensed by extreme cold and vaporises again; it can be watched as it oozes through stop-cocks or hurries through tubes, but in amount it is so small that it has not yet been weighed. Sir William Ramsay has treated it with a chemical cruelty that would well nigh have annihilated the most refractory or permanent known element; but this evanescent emanation comes out of the ordeal undimmed and undiminished. Not content with manufacturing so remarkable a substance, the radium atom sends out three kinds of rays, one kind being much the same as Röntgen rays, but wholly different in ionising power, according to the experiments of Strutt. Each of these consists of particles which are shot out, but they have different penetrative power. They are differently deflected by magnets and also by electricity, and the quantity of electricity in relation to the weight is different, and yet the atom—the same atom—remains unchanged and unchangeable. Not only this, but radium, or its emanation or its rays, must gradually create other bodies different from radium, and thus, so we are told, one at least of those new gases, which but yesterday were discovered, has its origin.

Then, again, just as these gases have no chemical properties, so the radium which produces them in some respects behaves in a manner contrary to that of all proper chemicals. It does not lose its power of creating heat even at the extreme cold of liquid air, while at the greater degree of cold of liquid hydrogen its activity is found by Prof. Dewar to be actually greater. Unlike old-fashioned chemicals which, when they are formed, have all their properties properly developed, radium and its salts take a month before they have acquired their full power (so Dewar tells us), and then, for anything we know to the contrary, proceed to manufacture heat, emanations, three kinds of rays, electricity, and gases for ever. For ever; well, perhaps not for ever, but for so long a time that the loss of weight in a year calculated, I suppose, rather than observed, is next to nothing. Prof. Rutherford believes that thorium or uranium, which act in the same kind of way, but with far less vigour, would last a million years before there was nothing left, or at least before they were worn out; while the radium, preferring a short life and a merry one, could not expect to exist for more than a few thousand years. In this time 1 grm. of radium would evolve one thousand million heat units, sufficient, if converted into work, to raise 500 tons a mile high; whereas a gramme of hydrogen, our best fuel, burned in oxygen, only yields thirty-four thousand heat units, or one thirty-thousandth part of the output of radium. I believe that this is no exaggeration of what we are told and of what is believed to be experimentally proved with regard to radium; but if the half of it is true, the term "the mystery of radium" is inadequate; the miracle of radium is the only expression that can be employed.

With all this mystery before us, which I must confess myself wholly unable to follow, I feel sure that members of the association who are interested in the work of this section will welcome the discussion, for which our secretaries have been able to arrange, and hear from the lips of Prof. Rutherford the conclusions to which his researches have at present brought him. No one is more fitted than Prof. Rutherford to open such a discussion, for no one has attacked the theoretical side with such originality and daring, or with such ingenuity of experiment. As an example of the activity of mind and of research to which the activity of radium has given rise, I may mention the fact that the last number of the *Proceedings* of the Royal Society is wholly concerned with radium, there being four papers, all of the first importance, dealing with entirely different phenomena.

It is not my purpose to review these or the subject of radium generally; I am in no way fitted to do so. But I cannot well let the present opportunity pass of referring to another mystery of which a conspicuous example is now leaving us. I refer to the mystery of the comet and its tails. What is a comet? of what does its tail consist? Gravitational astronomy has told us for many years past that, compared with the planets or their satellites, a comet does not weigh anything. It weighs pounds or, perhaps, hundreds, thousands, or millions of tons; but in comparison with inconspicuous satellites it weighs nothing. Yet some of them as they approach the sun from remote regions begin to shoot out streamers, which pour away as though repelled by the sun, not being left as a trail behind the comet, as is so often supposed. These streamers, ejected towards the sun, bend round and pour away at speeds which are enormous compared with that of the comet itself, thus producing the tail. Now, these streams separate very often, and give rise to comets with two or three tails. Let me read one paragraph from "The History of Astronomy," by Miss Clerke: "The amount of tail curvature he (Olbers) pointed out depends in each case upon the proportion borne by the velocity of the ascending particles

Digitized by Google

to that of the comet in its orbit; the swifter the outrush the straighter the approaching tail. But the velocity of the ascending particles varies with the energy of their repulsion by the sun, and this again, it may be presumed, by their quality. Thus multiple tails are developed when the same comet throws off, as it approaches perihelion, specifically distinct substances. The long straight ray which proceeded from the comet of 1807, for example, was doubtless made up of particles subject to a much more vigorous solar repulsion than these formed into the shorter curved emanation issuing from it nearly in the same direction. In the comet of 1811 he calculated that the particles expelled from the head travelled to the remote extremity of the tail in 11 minutes, indicating by this enormous rapidity of movement (comparable to that of the transmission of light) the action of a force much more powerful than the opposing one of gravity. The not uncommon phenomena of multiple envelopes, on the other hand, he explained, are due to the varying amounts of repulsion exercised by the nucleus itself on the different kinds of matter developed from it." It is impossible not to be struck by the similarity both of phenomenon described and of language used in this paragraph and in almost any of the papers on radium. I know this mere superficial similarity is worth very little, if anything; but for centuries the sky has shown us a phenomenon still not entirely understood, and the inability to remove all difficulty by the aid of radium or similar material is no reason for dismissing the idea of connection without further thought.

The comet's tail is still a mystery. Let me take the most recent explanation, which was set forth only three months ago in the *Atrophysical Journal* in the United States. Those admirable experimentalists, Nichols and Hull, have for some years been investigating the back pressure exerted by the action of light upon bodies on which it falls. In this they have followed the Russian physicist, Lebedew, but in minuteness and delicacy of measurement, and in their successful elimination of disturbances, their results are unequalled. It is sufficient to say that, difficult and minute as the experiment is, their success is such that the discrepancy between the calculated force and that which they have found is under 1 per cent. Perhaps I may express some satisfaction that in this measurement use was made of the quartz fibre. Having now definite and accurate confirmation of the existence of the force produced by the action of light, or rather radiation, Nichols and Hull proceed to examine the question as to how far such repulsion may be competent to overcome the gravitative attraction of the sun and drive away the matter which pours out from the comet. It is interesting to note here that Kepler put forward this very idea, and that Newton, the inventor of the corpuscular theory of light, looked upon the suggestion with some favour.

Coming now to this recent paper of Nichols and Hull, we find first the consideration of the relation of the attraction by gravitation, and the repulsion by light upon particles of different sizes and densities. Density has no influence on the action of light, while it is favourable to gravitation, and therefore unfavourable to tail formation. Size is favourable to both, but more to gravitation than to light, for if the diameter of a particle be doubled, one is increased eightfold and the other only four. So size favours gravitational attraction. Conversely, of course, smallness favours repulsion by light, which relatively should get greater and greater as the particles diminish in size. At last, then, a a degree of smallness may be reached in which the repulsion by light will actually be equal to the attraction by gravitation, and such a particle would remain in space, its motion unaffected by our sun. Let the diminution of size continue, and then the repulsion will be in excess, and if the law were to continue it would with sufficient diminution become relatively as large as we please. The law, however, does not continue. Schwarschild has shown that when the particles are small enough, light does not act upon them in the same way. Owing to diffraction, the effect of light is unduly great for a certain very small size of particle, while it fails almost entirely when the particle is made much smaller. Thus it is that the indefinite increase in the repulsion by light as compared with the attraction by gravitation with diminution of size of particle is checked, and when, according to theory, with a particular density of particle, the light pressure is about 20 times as great as gravitational attraction, further diminution of size ceases to favour the action of light, and it begins to fall off again. The distance of the particle from the sun has no influence upon the relation between the two kinds of forces, for they rise and fall together. Nichols and Hull, therefore, while not denying that other causes may operate, believe that light pressure is adequate to account for the phenomena, and that where the material coming from the head or comet proper is of two or three kinds, whether of density or of size of particle, the separation of the two or three tails should naturally follow. This theory presupposes that the nucleus of a comet will be able, owing to the evolution of gas under the sun's heat, to send out enormous quantities of dust, the finer and lighter the better, so long as it is not unduly small with respect to a wave-length of light. Such dust would account for any reflected solar light that the spectroscope may show, but it is not easy to see how the spectrum of hydrocarbons, of sodium, and of other metal, should be produced for lack of temperature. It is not easy to see why fortuitous dust should be graded of such sizes as to give well separated and defined tails; it is not easy to see how the dust could be produced in sufficient quantity to provide visible illumination to millions of millions of cubic miles of space through which it may be passing at ultra-planetary velocity, even though in looking through a million miles or so one grain of dust in a hundred miles might suffice to supply the light.

Other theories of the comet's tail require an electrified sun, the existence of which is explained by Arrhenius as being caused by the emission by the sun of negatively charged electrons which, picking up condensing gases as Aitkins's dust picks up moisture from the atmosphere, are driven away by the light pressure. Arrhenius believes that these acting on the matter in the tail would give rise to the bright line spectra which have been observed. The result of all this escape of negative electricity is a positively charged sun, but what limits the charge in the sun it is difficult to see, as it is, why the electrostatic attraction helped by gravitation does not ultimately stop the action. I may be displaying my ignorance, of which I am sufficiently sensible, but I am not aware of any evidence for the existence of the stream of electrified grains or drops imagined by Arrhenius. Nichols and Hull, while calling to their aid the researches of Schwarzschild to give them a repulsive force some 20 times as great as gravitative attraction, do not seem to have given due weight to the extremely small range of size of particle for which this high effect is available. The maximum effect for any wave-length according to Schwarzschild is produced when the size is such that a wave-length will just reach round it—that is, with ordinary light when the diameter is between one hundred thousandth and one hundred and fifty thousandth of an inch. If the diameter is $2\frac{1}{2}$ times the wave-length the action of light is only equal to gravity with a material of the density of water; or, again, if it is reduced to one-eighth of a wave-length it again becomes equal, and in these two cases there is no resultant action. With either larger or smaller particles gravity rapidly gets the better of light, while the high advantage of light over gravity is confined to very narrow limits. What the sifting process can be that will give rise to such a quantity of this microscopic dust we can hardly expect to be told, nor why even if the material should in some mysterious way be graded; the ungraded wave-lengths of the solar spectrum should allow of the marked separation in some instances of comets' tails. One thing, however, they do assert, and that is the light pressure can have no action on a gas, so that if what we see is considered to be gaseous, the light pressure theory must be thrown over for some other.

I cannot leave this excursion of Nichols and Hull into a speculative domain of science without expressing my admiration of the experimental work which they have accomplished, or of my appreciation of the ingenuity and daring with which they have attempted the hitherto unheard-of feat of making a comet. While the theory just referred to may be the most recent, it must not on that account be supposed to displace all that has gone before; the authors themselves do not suggest this—it is the last thing that would occur to them. They have referred to the researches of Bredechin that occupy so large a proportion of the annals of the Observatory of Moscow. It is impossible to read even a tithe of these without feeling that the subject of comets and their tails is one which Bredechin, by his amazing industry, has made his own property, and that any stranger casually passing by and taking a random shot should receive the severe penalty awarded to poachers in this country. Bredechin has dealt unmercifully—I do not say unjustly—with the author of at least one such random theory.

It is, therefore, with the greater diffidence and more urgent plea for forbearance that I venture to draw certain parallels and hazard certain suggestions which I admit freely have not reached a stage at which detailed comparisons with known comets are possible. It does not seem possible now to contemplate the phenomena of the comet, of the divided tails, of their tenuity and transparency, of the pale luminosity, partly reflected solar light, partly light as from a glowing gas; of the gradual wearing out and disappearance of those comets which constantly pay visits to solar regions, with all the mysteries of radium now so much in evidence without tracing the features in which they resemble one another. By radium, of course, I mean any material with the remarkable radioactive properties that radium exhibits with such pre-eminent splendour, whether known in the laboratory or not. How many physicists have been peering at comets through radium spectacles, or how many astronomers detect the sparkle of radium in the fairy tresses of their hirsute stars I know not. One writer, however (T. C. Chamberlin) so long ago as July, 1901, looked upon a connection between radioactive materials such as were then known and comets as at least worth considering. Chamberlin's paper in the *Astrophysical Journal* was mainly on the tidal disruption of gravitating bodies and the possible evolution of comets,

Digitized by Google

nebulæ, and meteorites, and he did not pursue this consideration in any detail; indeed, the enormous accumulation of new properties of radium was not then available.

Whatever may be imagined as to the constitution of a comet, difficulties still remain. All I suggest now is that the curious properties of radium and of similar bodies should be kept in mind. Radium at least supplies the means by which, if the increasing warmth or the tidal action of the sun should awaken its activity, Rutherford's α-rays should be shot out at the speed that he has measured of a thousand million inches a second—*i.e.*, one-twelfth the velocity of light. These α-rays, according to Rutherford, consist of helium; they weigh each twice as much as a hydrogen atom, and so the same weight of comet matter that would make one of Nicholl's and Hull's best particles—*i.e.*, one that would be just visible with a microscope—would be sufficient for about 400 millions of Rutherford's α-ray particles, an advantage surely where diffuseness seems so miraculous. These particles, shot out at a velocity one-twelfth that of light, go so fast that, if they were to start horizontally on the surface of the earth, the gravitative attraction of the earth would curve their path to the infinitesimal extent of a curve with a radius of forty thousand million miles. Yet so great is the electric charge they carry that a visible curvature can be imposed upon them in a practicable electrostatic field. Now imagine these transferred into space at a distance from the sun, for instance, equal to that of Venus. Gravity there due to the sun is only one-thousandth of what it is here, so gravity there would be, to the same extent, less able to impose visible curvature on their paths. But their electric charges are still available, and unless I have made an arithmetical blunder of a considerable order, it would require no heavy electrification of the sun to bend these rays round in a curve with a radius of 1,000 miles. An electrostatic field of under two ten-thousandths of a unit should be sufficient, a field which would be produced if the sun were only charged with a surface density of one electrostatic unit on every three square centimetres. Whether these figures are correct or not—and I know the risk of getting just thirty thousand million times too large or too small a result—does not much matter. An electrified sun, which after all others besides Arrhenius have postulated, would be sufficient to turn the rays and send them away at rapidly increasing speed so as to form the tail. The speed would in a short time reach the velocity of light if it were not for the change in properties of matter which supervenes when any such velocity is nearly reached. Thus, according to the ratio of charge to mass, particles such as Rutherford's α-rays would be sent away each with its limiting velocity, giving rise to streaks more or less well defined, and double, triple, or multiple according to the number of kinds of rays which the various radioactive materials were able to generate. Not only should streaks pointing away from the sun be formed, but any negatively charged rays such as radium is said to give out should form a tail directed towards the sun. Perhaps this might be expected to be general, but while not common, one was described by Hind in the comet of 1823-4, and three or four more have been observed. The head or coma would be the envelope of all the independent orbits, leaving the nucleus in all directions—orbits which while their velocities are still of the Rutherford order, would be hyperbolas convex to the sun. If this should not appear to be absolute nonsense, it would seem as if another difficulty should become less than it has been. I refer to the visibility, luminosity, and spectral character.

Lodge, as an interpreter of Larmor, tells us that an electrified ion subject to acceleration, whether transverse or in the line of motion, radiates energy. The streamers from the nucleus subject to the greatest acceleration may be bright almost as the nucleus itself. Then, as they have become dissipated into regions where far less acceleration becomes possible, the radiation falls off and the tail is lost in space. The observations made last month by Sir William and Lady Huggins of the spectrum given by a piece of radium in the air may have some bearing upon the luminosity of the comet. It is possible that the internal motions set up by the separate parts, each pursuing its individual orbit, may produce collisions numerous and violent enough to account for all the light that is seen, and for temperature sufficient to bring out the spectral lines that have been identified. Whether this is so or not, radioactive bodies and their emanations can produce light independently of such action; and now these observers have found that in the case of radium in air this light gives the spectrum, line by line, of nitrogen. Is it possible that the enveloping nitrogen has had its atoms so harried by the activity of the radium as to give a response hitherto only awakened by electric discharge? The ability to obtain such a response opens up a new possible interpretation of these spectra, which hitherto have been assumed, with our laboratory experience only to guide us, to have required for their production temperature above a red heat. If further observation should confirm this, the hydrogen, the hydrocarbon, and possibly even the sodium or iron spectrum that has been observed may have come from cold atoms; and it is not even quite beyond the limits of imagination to picture, not from the comet matter itself, but from loose residual and highly attenuated matter through which the comet is passing. There is one other feature of this remarkable observation of equal interest. The lines of the spectrum were not exactly in their proper place, but were all shifted towards the red end of the spectrum about twice the distance between the D lines. If only one or two lines had been so observed, a different origin might well have been suspected; but when the whole series are faithfully reproduced it is reasonable to look upon the spectrum as modified to that extent as though the works of the nitrogen atom had not only been set in movement, but had been loaded with the radium emanations.

Before dismissing these random speculations on the possible connection between radioactivity and comets I would ask your leave to refer once more to Bredechin's conclusions. He has found that it is merely necessary to postulate three kinds of matter, issuing from the nucleus with three initial velocities, and subject to repulsion from the sun with three sets of forces of repulsion—*i.e.*, as compared with ordinary gravitative attraction—for the whole of the phenomena of all sorts of comets to be very completely accounted for. His highest initial velocity is only about five miles a second, and his lowest about a quarter of a mile a second. His highest repulsion, after deducting gravitative attraction, is only 11 times gravity, and his lowest only a fifth of gravity. If, then, with such velocities and forces the phenomena can be exactly accounted for, it would seem futile to consider the possibility of initial velocities from 4,000 to 80,000 times as great and effective repulsions of a corresponding order being able to produce effects with anything in common. This is not necessarily the case, for with the comparatively slow separation of the atoms of Bredechin's matter from the nucleus, each one describing its own hyperbola convex to the sun, the tail at any moment represents the then position of any number of atoms which left the nucleus for some distance back, whereas with the enormous velocities and effective forces now discussed, the comet moves so slowly in comparison that the tail would practically represent the path at the time. It has taken me far longer to throw out this not very luminous ray than I had expected or than it is worth. I fear that it is a sort of ray in which the ratio of its dead weight to its vitalising charge is too small to enable it to penetrate the lightest screen of examination. These are the days of rays, and now before we have quite become familiar with the rays of radioactive bodies, Blondlot has presented us with N-rays, which, issuing from the mantle of an incandescent gas burner, penetrate wood or aluminium, and then increase the light without increasing the heat of hot bodies on which they fall.

Passing now from the amusement of speculation to more serious duties, I find myself confronted with the difficulties that prevent us in this country from succeeding as we used to do in the international struggle—a struggle the issue of which is daily becoming more and more a question of brains, of education, of skill and enterprise in manufacture—and finally of that great virtue extolled by the President of the United States, strenuousness. It is the duty of everyone who see the way in which we are being outstripped in the race to do what in him lies to scrape off the rust which is clogging our educational machinery. I now refer to the defects which hamper the intellectual progress of the majority of our youth. I believe the public school mathematics in this country stands on a level of its own, well below that of any other. In England, owing to our complicated system of weights and measures, which our Ministers and our Parliament dare not abolish for our own good, the scanty hours allowed for mathematics are devoted to the learning of tables which should never have to be learned at all, to compound reductions designed merely to puzzle but not to lead to any new step; and, even if our present system were not futile enough, to learning lists of antique values which serve the useful purpose of giving the boys something to do. The result is that beyond having time to acquire a few elementary algebraical rules the boy is never introduced to algebra proper; he has no idea of algebraical reasoning; his trigonometry often does not exist, and the very sound or suggestion of co-ordinate geometry or of the differential calculus, which might be well within his reach, produces a shiver of dismay. Geometry is presented for the first time in the form of Euclid, a form as repulsive to most boys as it well could be. I must confess to having been attracted and not repelled by Euclid; but the boy does not care for time. Now that I look at Euclid again I have also to confess that any lingering regard for an old friend vanishes before the archaic language and the unnecessary circumlocution. If Euclid must be retained, let it be translated into English, the English that any parent would use in explaining the ideas to his son; let it be illustrated by constant reference to real things, so as to appeal to the boy who does not revel in the abstract. Let the ideas and the terms first be presented in the form of experiments and of measurements with instruments. Let the schoolmaster dare to throw over the intolerable conservatism which prevents our doing anything ten times as well unless some item should prove to be a trifle worse; in fact, let us take some heed of the possibly

Digitized by Google

extreme, but none the less genuine and valuable, preaching of Prof. Perry. I have so far referred only to the miserable use that is made of the odd hours gradually given to what is called mathematics. Is it any use to repeat the long-standing complaint of the way in which the schoolmaster insists upon overdoing his Latin and Greek under the belief that they are at least essential to intellectual development, if, indeed, they do not supply the only stimulus? As society is constituted, they are essential to education as an extensive knowledge of Confucius is essential to an educated Chinaman, so that we may mix one with another, appreciate the works of our great authors, understand the same allusions, and have the same kind of knowledge of the development of our civilisation. Few men of science, perhaps none, wish to see all of this, some of which is essential to a general education, abolished; all that we ask is that the schoolmaster shall not continue to impose upon the community the unbalanced learning which corresponds to mathematics and science without letters. The time given to classics is exorbitant; more must be reserved for those pursuits which draw out the habit of independent thought, creation, and originality. It would be well if every schoolmaster could read an admirable article by James Swinburne on the two types of mind fostered by the two complementary types of education, but this is buried away in an inaccessible number of the *Westminster Review*.

The classic is unfortunately still in possession, and where, as is still often the case, he is innocent of any appreciation of the educational value of post-Newtonian studies, it is not surprising that he thrusts into odd moments the subjects he does not understand, and which he therefore despises, and that the boys committed to his charge and living in such an atmosphere are half ashamed of showing any interest in the scanty science which is within their reach. It is almost impossible to believe that such can be the case, but I have referred to the impression to which the appointment of the first science master at my own school gave rise. I now refer to the contribution to a discussion on education but a year or two ago by that experienced teacher, Principal Griffiths. Fortunately our public schools are not the only ones in the country. Smaller and less fashionable schools pay more attention to education and suffer less from what, in defiance of all rule, I can only call didactatorial method. I am not aware that the result of this almost total exclusion of tabooed subjects in favour of Latin and Greek is producing a standard of classical attainment in our youth greatly in advance of that to be found in other countries, but it is certain that in history, modern languages, mathematics, and science the product of our public schools is sadly deficient.

There is another point related to our deficient general scientific training on which I wish to offer some remarks, and that is in relation to manfacture. It is the fashion among some of our scientific people to talk of our manfacturers as if they were a very ignorant lot, and to suppose that one word from some professor who has never seen outside a laboratory would be sufficient to put them right. Now, in my somewhat varied experience I have had occasion to become acquainted with corners of our great manufacturing areas, and, while my experience is small and not enough to generalise upon, it is, nevertheless, several times as great as that of some who are ready to adopt the superior attitude, but have none. The loss of one industry after another is only too patent. In so far as this may be due to want of enterprise in our men of business, we are not concerned with the cause in this section; in so far as it may be due to want of that little assistance which the fiscal arrangements in other countries make possible for our rivals, again we are not concerned in this section; in so far as our patent laws are unique among those of manufacturing nations in allowing the foreigner to manufacture in his own country under the protection of our patent law, so that the most valuable school we possess—the manufactory—as well as the manufacture, is conducted to the advantage of our rivals—a point which I suppose it is unnecessary to commend to the notice of Mr. Chamberlain—with this, too, we have no concern in this section; but in so far as this, or the want of enterprise or of foresight that leads to it, is due to ignorance and to want of appreciation of scientific advance, we are very much concerned with it. If I may refer to my own limited experience, there is a lamentable contrast in the manner in which a great number of our countrymen look at any proposition put before them and that in which the alert American does. It is useless to explain that which would be self-evident to a man with a moderate knowledge of chemistry and physics such as our schools ought to supply, or for which they should at least lay the foundation, for the words have no means; they are merely words. He distrusts anything new; he has heard of a new process before that did not work out well; experience on the Continent to him is no experience at all, for he believes the inhabitants in such distant parts of the earth are not capable of knowing as well as the enlightened Englishman whether a thing is properly done or not, and so he goes on as he did before, perfectly content. This attitude would not be possible with the most elementary understanding of common principles.

But there is another side to this picture. Anyone who has discussed any scheme with the board of directors, the manager, the engineer, and the chemist of one of our great manufactories must have been struck with the concentrated ability there found in harness. It has often seemed to me that it is a great misfortune that our professors of mechanics, of physics, and of chemistry, are in so many instances precluded from a better acquaintance with the working of these great machines—a misfortune not for the works, at least directly, but for the professors, and more especially for their pupils. Nowhere are scientific problems of greater complexity constantly having to be solved than in a great manufactory; nowhere is such concentrated talent necessary as in a works organised and carried on in competition with all the world. I look upon these as our most valuable schools, and the closer the touch between them and those whose province it is to teach, the better for the teacher and the pupil.

It is, perhaps, hardly desirable to mention any one where there are so many. I am tempted to dwell upon the problem which has been at last successfully solved by Parsons, this being the joint product of the school and of the works; but there is one picture—a contrast, I will not say of light and shade, but of colour and colour—to which I must refer. I remember in my early days, in the surroundings of a classical atmosphere, the general feeling of contempt for the manufacturer, the intellectually inferior creature who only made money, but who knew nothing of τυπτω or τέτυμμαι. I am not sure that some such feeling does not still exist among those whose horizon is limited to the Latin and Greek that they have learned—or should I say limited *by* instead of *to*? This recollection came back to me when not long ago I was visiting one of the best organised and most skilfully conducted works in the country—I mean Willans and Robinson—when I remembered that another great manufactory, conducted on American lines, was near by, and when across the road I saw the walls of one of our most famous English schools. I pictured the old contrast. On the one hand, the conviction impressed upon me when a boy that there is something intellectually superior in the struggle with a paragraph of Xenophon or a page of Homer, while manufacture is merely mechanical, sordid, and base, with what I believe to be the reality on the other. I wondered in what spirit the erection of these works was viewed at the school, and to what extent the high intellectual attainment there so essential and so evident is properly appreciated. Of the last of the three headings, Strenuousness, we have plenty, but at school it is most apparent in cricket and football, and in after life in various expensive ways of murdering defenceless animals. However, a change is already beginning to be felt. The public schools no longer withhold the elements of chemistry and physics, and those who have benefited, even in small degree, are taking responsible places vacated by those who had no such opportunity. The numerous polytechnics are providing more serious instruction to thousands of our young men, and it may be hoped that in time even the official—I mean the mere official whose only conception of activity is centred in obstructing progress and enlightenment—will have some appreciation of things as well as of words.

ON THE NATURE OF THE EMANATIONS FROM RADIOACTIVE SUBSTANCES.

The discussion on the above interesting subject was opened on Thursday, the 10th, in Section A, by Prof. E. Rutherford, F.R.S.

Prof. RUTHERFORD commented on the fact that the subject of radioactivity was a comparatively new one, having been under investigation only seven or eight years. He proposed to confine himself to the nature of the rays and emanations from thorium and radium. It was first discovered that the activity of thorium was very varied and depended on air currents. It was then proved that there was a continual emission, but that the rate of emanation depended on local circumstances. It was found that the radioactivity of the emanations fell off with time. For instance, the activity was reduced to one-half after one minute, and to one-quarter after two minutes. Later experiments on radium revealed a similar action, although in this case the radioactivity was a million times more powerful. With the radium emanation the rate of decay reduced the activity by one-half in four days. The question then arose as to what were these emanations. It was clear that they were not dust, because they did not form centres of condensation of moisture. Their size had been approximately determined by the diffusion into gases, and from these experiments it was apparent that

Digitized by Google

they were roughly 100 times the hydrogen atom. They acted like a gas, in that they do not pass through mica. An experiment with 20 milligrammes of radium bromide went to show that the rate of production of the emanation was constant under all conditions, and that they could be separated from the radium suddenly by dropping the radium bromide into water or by heating it. The action was as though the emanations were occluded in the substance as a gas would be, and then given off by heat or water. In the same way tubes of celluloid through which the emanations were passed seemed to occlude them. If the emanations were passed into a tube surrounded by liquid air, they seem to be condensed and remained in the tube. They were given off again when the temperature was raised to – 150deg. C. for the radium emanations and – 120deg. C. for the emanations from thorium. This action could be watched by the eye owing to the light given off by the radioactivity of the emanations. In order to prove if the emanations had any chemical properties, they had been passed through solutions which would stop any known gas. It followed, therefore, that, if a gas, they could only belong to the inert argon family. From these emanations positively charged bodies were thrown off which were atomic in size with a velocity equal to one-tenth that of light. The mass of these bodies was twice that of the hydrogen atom, and they possessed, therefore, enormous kinetic energy. For equal mass they had about 16 hundred million times the energy of an ordinary rifle bullet mass for mass. Through the interesting experiment of Sir William Crookes, the impact of these bodies on a screen had been rendered visible. The effect was that of small spots of light like the stars in the heavens, and he believed that it was the first time that what seemed to be the action of single atoms of matter had been rendered visible. It would seem, therefore, that these emanations which behaved like a gas threw off matter at very high velocity. The most reasonable explanation of this was to suppose that the rotational atomic velocity had suddenly been set free to move off at a tangent at enormous speed. It was curious that the emanations from 14 to 15 milligrammes of radium bromide, although they gave from 2 c p. to 3 c.p., could not be collected in sufficient quantities to be either weighed or seen. It was also found that if the emanations were passed through a tube or over a body, the tube or body became radioactive. This activity also decays, and it was found that the excited radioactivity from thorium was reduced to one-half in 11 hours, and that from radium was reduced to one-half in about half an hour. This excited radioactive substance could be dissolved by certain acids, but not by all, and if the solution is evaporated the active matter remains. The law of the rate of decay of radioactivity was found to be a geometrical progression in all cases, and in spite of the influence of any known physical condition. Alterations in temperature or concentration had no effect on it. In fact, the rate of decay seemed to depend on the number of atoms thrown off, and this was only dependent on the number of atoms present. As temperature had no effect whatever, the action was not likely to be chemical. The question arose as to what became of the residue after the positive discharges had been thrown off. He believed that the residue was responsible for the deposited activity on the tubes. It would seem as though the bulk of the radium atoms were stable, and that only one or two became unstable at a time. The process of breaking up of the atom then seemed to take place in four stages. First, there was the radium; secondly, the emanation which is radioactive; thirdly, the other matter carried over with the emanation which has the power of exciting radioactivity in other substances, and is associated with the emission of particles or rays of a very penetrating kind analogous to the Röntgen rays; and, fourthly, the final break up of the atom, which seems to result in the production of helium. This production of helium seems to be a matter of time, as the tube which contains the residue does not give the helium spectrum at first. After being kept for some days the helium spectrum is easily obtained.

Sir OLIVER LODGE said he was pleased to take part in the discussion on the most interesting information which had been given by Prof. Rutherford. He considered that he clearly put forward a theory as to the breaking up of the atom which was distinctly a working hypothesis, as it covered the facts without any forcing. It had now been ascertained that the radioactive emanations thrown off by radium left behind radioactive material. We seem to be seeing substances in transition stages, and the theory put forward as to the disintegration of atoms agreed with the ideas expressed by Dr. Larmor seven years ago. Without doubt the chemist would say that if the radium atom breaks down and throws off helium, it would be correct to say that it is not an atom breaking down, but a compound breaking up. There was, however, a very strong argument against the action being due to chemical action. It was not affected by temperature. Sir Oliver Lodge then read a communication from Lord Kelvin on the subject, in which considerable doubt was thrown on parts of Prof. Rutherford's theory. Lord Kelvin considered that the continuous emission of heat pointed to energy being supplied from without by etheric waves. As a physical example of a similar action, he instanced two glasses of water, in the one of which was a piece of white cloth and in the other a piece of black cloth. If these two glasses were placed in sunlight, the one with the black cloth would get hotter that the other. He suggested that the experiment as to heat emission from radium should be repeated inside a heavy lead vessel.

Prof. H. E. ARMSTRONG, speaking as a chemist, was astonished by the imagination of the physicists. They had had no opportunity of making thorough chemical investigation into properties of radium, owing to its scarcity. He would say, however, that in the whole range of chemical knowledge there was absolutely no evidence of atomic disintegration taking place under earthly physical conditions. He looked upon radium rather as a new kind of screen for picking up radiations.

Mr. W. F. SODDY said he had been privileged to work with Prof. Rutherford in his experimental researches, and as regarded the theory put forward, it was an exceedingly simple one that covered all the facts. The properties of radium had been fully investigated by Madame Curie, who found its atomic weight to be 225, and that its properties were exceedingly like those of barium. It would seem from their experimental evidence that in the mass of radium as a whole the change was so slow as to be inappreciable, but that individual atoms were liable to a sudden change. Prof. Armstrong in a recent paper on the subject had explained that all such exothermic changes were usually explosive: that was so because such changes were usually accelerated by change of temperature. He thought that Prof. Armstrong was wrong when he said that the chemists had no evidence of atomic disintegration. When experimenting with pitchblende Madame Curie had discovered, by means of its radioactivity, the presence of such a small quantity of a substance that could not be determined by ordinary chemical means. She then succeeded in isolating the radium compound, which had distinct chemical properties. He looked upon the means by which this discovery had been made as similar to spectroscopic analysis, which was now fully recognised as a weapon of the chemist in the same way. The revealing of the presence of exceedingly small quantities of materials by their radioactive properties could justly be termed chemical evidence.

Prof. DEWAR described in detail an interesting experiment he had made on the sample of radium bromide which Monsieur and Madame Curie had used in their Royal Institution lecture. He had placed it in liquid hydrogen, which was contained in a vacuum-jacketed vessel, the whole being surrounded by liquid hydrogen. In this way the evaporation of the liquid hydrogen in the inner vessel gave a calorimetrical determination of the evolution of heat from the substance. It clearly proved that the emission of heat was independent of the temperature of the surrounding media. Indirectly, it also showed that any sample of radium bromide after being prepared took some time to make its maximum rate of heat emission as the constant, for the sample in question was considerably below that for older samples in the possession of the Curies.

There were other speakers on the subject, whom we regret we have not space to report.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

CO-OPERATION IN SCIENCE.

The Southport meeting of the British Association has now been concluded, and it is interesting to read the various opinions in the daily Press as to its success or otherwise. Unfortunately, these opinions are frequently influenced quite as much by the livers of the writers as by the actual transactions of the various sections of the association. As far as numbers are concerned, the meeting shows a distinct advance over that held last year in Belfast, but the total number of tickets issued was below that for the previous meeting at Southport some twenty years ago. It is not, however, to the numerical strength only which one must look for success in such an association, as the meeting together of the leading members of the scientific world is the real object to be attained. In this respect it seems to us that the 1903 meeting is quite equal to any of its predecessors of recent times. Quite a large number of the papers were contributed by foreign scientists, and this was particularly the case in the meteorological division of Section A. The discussion "On the Nature of the Emanations from Radioactive Substances" attracted, perhaps, more general interest than any other purely scientific subject during the meeting, and it was very unfortunate that a larger room could not have been obtained for the purpose. As it was, the room allotted to Section A was overcrowded for three and a-half hours on Thursday, the 10th, and those who listened throughout to Prof. Vernon Boys's presidential address and to the discussion on radium suffered from emanations from other than radioactive substances. It speaks volumes for the interest displayed in the subject that hardly anyone in the large audience left the room, in spite of the discomfort caused by the want of ventilation. The discussion in question was introduced by Prof. E. Rutherford, F.R.S, who came from Montreal to lay before the meeting the results of his original investigations on the properties of radium and other kindred substances. Not content with giving concisely the results of his investigations, Prof. Rutherford went further, and propounded a theory which covered the facts in question. This theory will be found in the report of the discussion reproduced elsewhere in this issue. Speaking generally, it accounts for the extraordinary properties of the radium emanations, on the supposition that an actual breaking up of individual atoms is taking place. It would seem that this is a step-by-step process, and that experiments already made enable these steps to be distinguished the one from the other. The theory also involves the production of other elements during the breaking up of the radium atom. Thus spectroscopic analysis reveals the fact that the radium emanations in some way produce helium in course of time. The vast amount of energy which is evolved from radium is accounted for by the setting free internal kinetic energy of the atoms. It will be seen from the above that Dr. Rutherford's theory is a far-reaching one, and that if supported by further experiments it will lead us in the direction of the alchemist's dream—*i.e.*, the transmutation of matter. As was to be expected, any new theory of this kind meets with considerable opposition on its introduction, and there was no exception to this in the discussion at Southport. Lord Kelvin, who unfortunately was unable to be present, forwarded a contribution on the subject, in which he suggested that the energy radiated from radium might be obtained by that substance from unknown external sources, such as etheric waves yet to be discovered. Prof. Armstrong, as an expert in chemistry, stated his opinion that there was no chemical evidence whatever of the disintegration of atoms under the physical conditions available on the earth. To this Mr. Soddy, who has

Digitized by Google

worked with Prof. Rutherford on the subject, properly replied that the investigations of Madame Curie in the isolation of very small quantities of radium from pitch-blende might properly be classed as chemical research, as radioactivity was evidence which could be used in the same way as spectroscopic analysis was by chemists. In Section G the contributions were more numerous than usual, and a number of them were most valuable. The feature of the meeting was perhaps the very great interest shown in the comparatively young section devoted to education. This section, which by order of organisation is called the "L" Section, filled at times the Cambridge Hall. On Tuesday last this room had, however, to be given up to the Economic Section for the debate on the fiscal question. This debate was very interesting, but it would have been much more useful if it could have been deferred until after the policy of the Government had been announced. As a whole the Southport meeting was, in our opinion, a great success, and it must have been most profitable to its members.

RETURN-CURRENT TROUBLES ON THE HAMBURG TRAMWAY SYSTEM AND THEIR PREVENTION.*

The return circuit on this system consisted practically entirely of the rails, bundles of bare copper wires being connected to them at various points near the supply station. Only very few distant return feeders were in use, and these carried a negligible proportion of the whole current.

Trouble with the gas-pipes first occurred in 1898, about a year after the principal part of the system came into use. The escape of gas became evident through the dying of several avenue trees through the escape of gas. Investigation showed that most of the streets in which trouble occurred had wrought-iron piping crossing the tramway track. In Fig. 1, which shows the profile of one of these

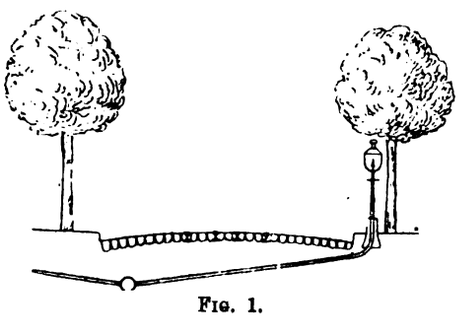

Fig. 1.

streets and is applicable to most of the others, it will be seen that the main cast-iron gas-pipe lies near to one curb, and from this main wrought-iron pipes branch off in both directions to the street lamps and houses on both sides of the road. It is only in recent years that the introduction of cement conduits carrying gas-mains on both sides of the road has enabled the wrought-iron cross pipes, which used to run at a depth of about ·7m., to be dispensed with. The powerful electrolytic action was only noticeable on those wrought-iron pipes which crossed the rails, and only at the parts under the rails. In the more dangerous neighbourhood, near the station, a few of the leaden water-mains, which also crossed the rails, but at a depth of 1·5m., showed a more advanced oxidation under the rails than at other parts, but no holes. Cast-iron pipes which crossed the rails were found to be unaffected, the older ones being protected throughout their length by a covering of oxide, which, if not entirely stopping the current, would at least greatly diminish it.

The insertion of a layer of concrete under the rails in one street to a depth of 20cm., and extending to a distance of ½m. beyond the rails on each side, had no effect in preventing electrolytic action. New tubes became appreciably attacked within six months in the worst district.

The electrolytic action was probably aided by the presence of a considerable quantity of salt in the fairly dry sandy subsoil. This salt had penetrated the soil after use on the surface for snow-melting purposes. Experiments carried out with a view to stopping the electrical action showed that tarred pipes gave more satisfaction than those covered with pitch. The pitch was applied in the form of a pitched tape wound on the pipe spirally, and the pipe became attacked spirally at the overlapping point. The current discovered badly-covered spots, and so damaged the pipes even more quickly than when they were bare, owing to the higher current densities attained. In spite of the rapid electrolisation occurring at certain points, the number of such points discovered was comparatively small, so that only a small proportion of the full tramway current, amounting to over 3,000 amperes, could have been leaking into the pipes. This was borne out by the fact that when one of the cast-iron 100mm. diameter mains in the principal street was cut for experimental purposes, a current of only about four amperes was found to pass through it.

After some further experiments, it was decided to protect the pipes by the employment of insulated returns to about the same extent as the feeders to the overhead trolley line. These returns were carried in cable troughs, and were connected to the rails at intervals by bare copper conductors embedded in asphalt in wooden troughs. For the purposes of calculation, it was found necessary to obtain some reliable figures as to rail and bond resistances, and some careful measurements of voltage drop with constant current were made on the standard steel rails in use. These were 10m. long, and had a cross-section of 6,464 square millimetres (10 square inches), and the average result obtained was ·00003 ohm per 1m. of rail without joints at a temperature of 29deg. C. Bonds between rails were made, as in practice, by means of two 8mm. diameter copper wires, and the measurements were then repeated across the bonds, but no noticeable difference from the plain rail could be noticed.

In order to obtain a record of the current distribution in the different return feeders, measurements of the potential difference existing between different feeding points were made by means of pilot wires and a voltmeter. The measurements were made during working hours, and each reading occupied one minute; the greatest deflection in each direction, or the greatest and least deflections in one direction, if all the deflections were to one side, were noted. On the strength of these measurements resistances were inserted into certain of the return feeders, and in this way considerable reductions in E.M.F. between neighbouring return feeder points were effected.

After the introduction of these return feeders and their adjustment by means of resistances, all trouble through electrolysis of pipes disappeared.

* Translation in abstract of a paper read by Freiherr V. Gaisberg at the eleventh annual meeting of the Verband Deutscher Elektrotechniker in Mannheim.

PERSONAL.

The lectureship in electrical engineering at the Hull Municipal Technical School has been filled by the appointment of Mr. G. W. Osborn Howe, M.Sc., of London. Mr. Howe has had a distinguished college career, and in 1900 was successful in obtaining the Senior Whitworth Scholarship. He graduated at the University of Durham with honours in engineering and physics. His practical experience includes six years in the shops, 18 months in designing and estimating cable work, and nine months in the calculation and design of electrical machinery, all with Messrs. Siemens Bros. and Co., Limited, London. He has further had two years of experience, chiefly in polyphase work, with Messrs. Siemens and Halske, Charlottenburg.

The salary of the electric engineer at Ayr (Mr. Marshall) has been fixed at £300. The salary of the assistant engineer (Mr. M. Henderson) has been raised from £2. 5s. to £3 a week.

Mr. Keenan, the assistant engineer at Taunton, has left, he having obtained an appointment at Torquay.

We are informed that Mr. A. Brandon, commercial manager of the Lahmeyer Electrical Company, Limited, has rejoined the staff of Messrs. Johnson and Phillips, with whom he was previously associated for about 12 years.

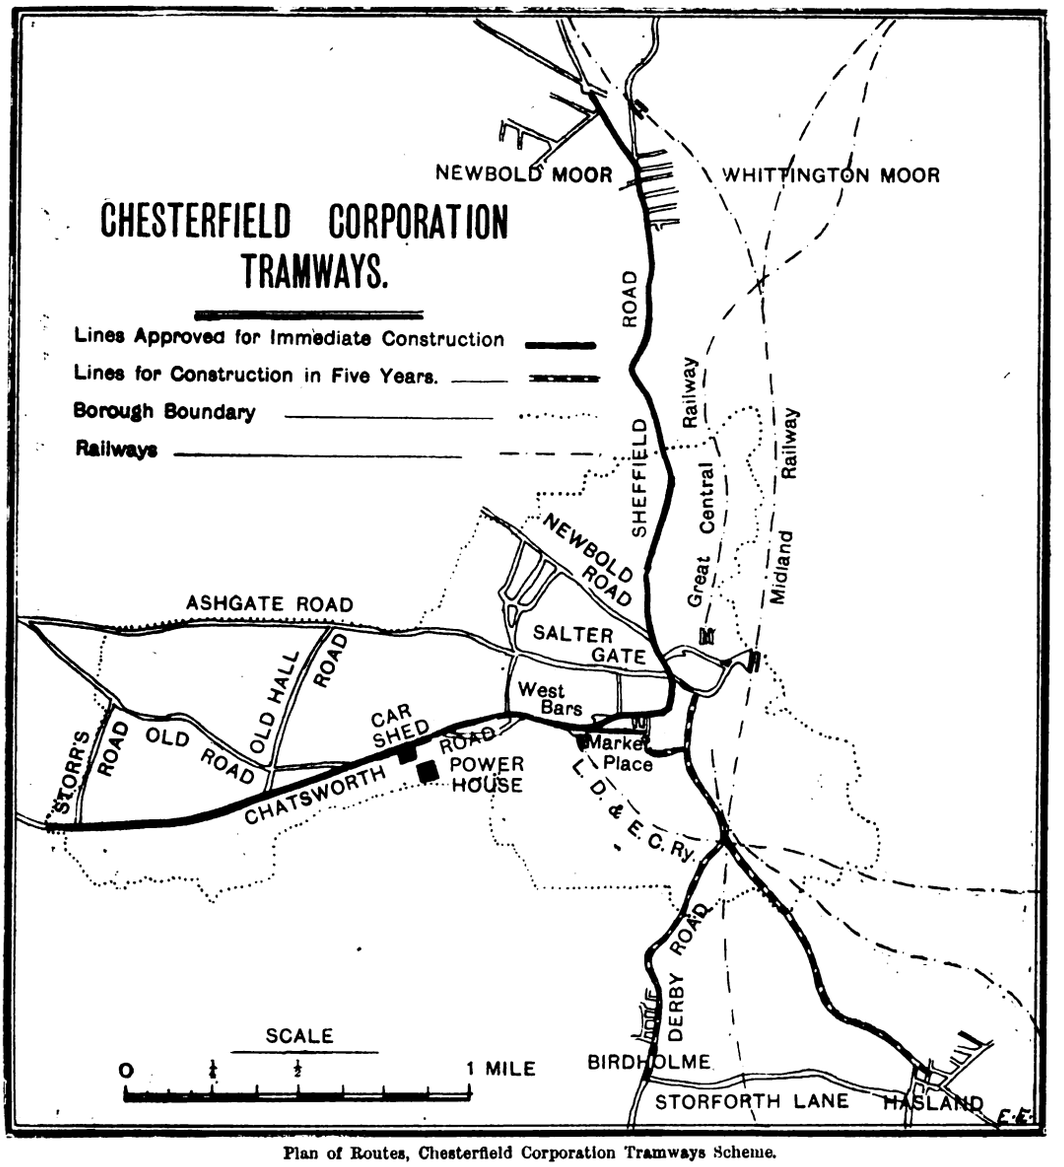
CHESTERFIELD CORPORATION TRAMWAYS SCHEME.

We are indebted to Mr. R. L. Acland, borough electrical engineer, Chesterfield, for the accompanying plan, showing the routes of the tramways which the Council have just decided to construct. The total estimated cost of these tramways, including the necessary equipment, is £86,808, of which sum £55,714 is required for the lines approved for immediate construction.



Plan of Routes, Chesterfield Corporation Tramways Scheme.

ON THE USE OF CAPACITIES AS MULTIPLIERS IN CONNECTION WITH ELECTROSTATIC VOLTMETERS ON ALTERNATING-CURRENT CIRCUITS.*

BY PROF. E. W. MARCHANT, D.SC., AND G. W. WORRALL, B.SC., LIVERPOOL UNIVERSITY.

The measurement of high potential differences necessitates the use of voltmeters more or less cumbrous and expensive, since in all electrostatic instruments there is a liability to sparking between the plates. High P.D.'s may, however, be measured by lower reading voltmeters in several ways. The only methods hitherto adopted have been by the use of non-inductive resistances connected in series with the voltmeter, either shunted or unshunted, and by the use of transformers. The first method becomes quite impracticable with high pressures on account of the large waste of power involved, while the latter method becomes equally cumbrous on account of the difficulties of insulation and the length of wire required in winding the apparatus. The experiments described below have been directed to the construction of a simple and easily made apparatus by which low-reading electrostatic voltmeters may be employed on circuits of much higher tension. The voltmeters used were of the Kelvin multicellular and Ayrton and Mather electrostatic types. The method of combining the voltmeter with the capacities is to connect a capacity in series with the voltmeter across the mains and shunt another capacity across the terminals of the voltmeter, the latter capacity being large compared with the capacity of the voltmeter. Fig. 1 is a diagram of the connections.

Consider two capacities connected in series across the mains.

Let C_1 and C_2 be the values of the capacities in farads;
R_1 and R_2 be their respective insulation resistances;
V_1 and V_2 be the respective P.D.'s between the terminals of the capacities;
E be the total P.D. between the mains;
I_R be the resistance current between the mains;
I_C be the capacity current between the mains;
I be the total current between the mains;
p be 2π (frequency per second).

$$\text{Total current in capacity 1} = V_1\sqrt{\left(\frac{1}{R_1}\right)^2 + (C_1 p)^2}$$

$$\text{Total current capacity in 2} = V_2\sqrt{\left(\frac{1}{R_2}\right)^2 + (C_2 p)^2}$$

These two currents being one and the same,

$$V_1\sqrt{\left(\frac{1}{R_1}\right)^2 + (C_1 p)^2} = V_2\sqrt{\left(\frac{1}{R_2}\right)^2 + (C_2 p)^2} = I.$$

* Paper read before the British Association, Southport meeting.

Digitized by Google

Now, $$E = \frac{I_C}{\frac{C_1 C_2}{C_1 + C_2} p} = I_R (R_1 + R_2).$$

Hence, $$I_C = E \frac{C_1 C_2}{C_1 + C_2} p, \text{ and } I_R = \frac{E}{R_1 + R_2}.$$

Now, $$I = \sqrt{I_C^2 + I_R^2} = E \sqrt{\left(\frac{C_1 C_2 p}{C_1 + C_2}\right)^2 + \left(\frac{1}{R_1 + R_2}\right)^2}$$

$$= V_2 \sqrt{\left(\frac{1}{R_2}\right)^2 + (C_2 p)^2}.$$

Hence, $$\frac{V_2}{E} = \frac{\sqrt{\left(\frac{C_1 C_2 p}{C_1 + C_2}\right)^2 + \left(\frac{1}{R_1 + R_2}\right)^2}}{\sqrt{(C_2 p)^2 + \left(\frac{1}{R_2}\right)^2}}.$$

Let $R_1 = \frac{x_1}{C_1 p}$, and $R_2 = \frac{x_2}{C_2 p}$. Then

$$\frac{V_2}{E} = \frac{\sqrt{\left(\frac{C_1 C_2 p}{C_1 + C_2}\right)^2 + \left(\frac{1}{\frac{x_1}{C_1 p} + \frac{x_2}{C_2 p}}\right)^2}}{\sqrt{(C_2 p)^2 + \left(\frac{C_2 p}{x_2}\right)^2}}$$

$$= \frac{\sqrt{\left(\frac{C_1 C_2 p}{C_1 + C_2}\right)^2 + \left(\frac{C_1 C_2 p}{x_1 C_2 + x_2 C_1}\right)^2}}{\sqrt{(C_2 p)^2 + \left(\frac{C_2 p}{x_2}\right)^2}}$$

$$= \frac{C_1}{C_1 + C_2} \frac{\sqrt{1 + \left(\frac{C_1 + C_2}{x_1 C_2 + x_2 C_1}\right)^2}}{\sqrt{1 + \left(\frac{1}{x_2}\right)^2}}$$

Expanding and neglecting higher terms—

$$\frac{V_2}{E} = \frac{C_1}{C_1 + C_2} \left\{1 + \tfrac{1}{2} \left(\frac{C_1 + C_2}{x_1 C_2 + x_2 C_1}\right)^2 - \tfrac{1}{2} \left(\frac{1}{x_2}\right)^2 + \ldots\right\} (1)$$

If x_1 and x_2 are very large—that is, if the insulation resistances of the condensers are high—then

$$\frac{V_2}{E} = \frac{C_1}{C_1 + C_2}.$$

From equation (1) it will also be seen that if $x_1 = x_2$, that is if

$$\frac{R_1}{R_2} = \frac{C_2}{C_1}; \text{ then } \frac{V_2}{E} = \frac{C_1}{C_1 + C_2}.$$

This will most probably be the case if the plates of both capacities are of the same size and the sheets of dielectric

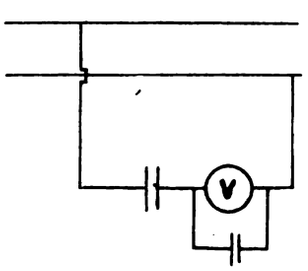


Fig. 1

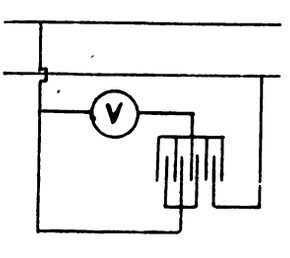

Fig. 2

of the same material, size, and thickness, the difference in the values of the capacities being produced by using different numbers of sheets, since, then, both leakage currents through the material and those over the surface of the dielectric will be proportional to the number of plates forming the condensers. If an electrostatic voltmeter, therefore, be connected across the capacity 2, its reading bears a constant ratio to the P.D. between the mains, and by varying C_1 and C_2 any desired ratio may be obtained. Several advantages, such as compactness and saving of material, are gained by forming the two capacities into a condenser, in which one of the two sets of plates is itself divided into two groups, each group connected to its own related main, one group to the voltmeter, and the voltmeter again to the undivided set, as in Fig. 2.

Two instruments have been constructed up to the present on the principles described. One suitable for measuring P.D.'s up to 300 volts on a 150-volt instrument and having a ratio of $\frac{1}{2}$, and the other suitable for P.D.'s up to 10,000 volts having a ratio of $\frac{1}{40}$. Fig. 3 is an illustration of these instruments. Fig. 4 is a diagram showing the arrangement of the low-tension instrument. This is formed of alternate sheets of mica and tinfoil of equal

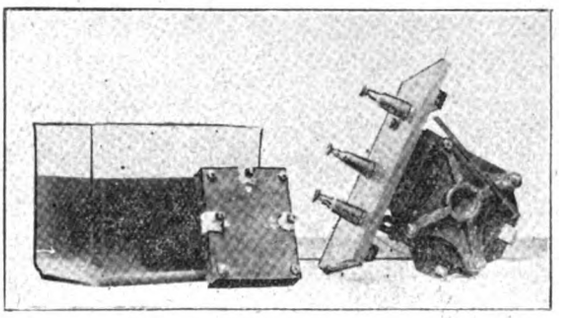

Fig. 3.

dimensions respectively, held together between strong plates of ebonite. Fig. 5 is a diagram showing the arrangement of the high-tension instrument. This is similarly formed, except that copper-foil is substituted for tinfoil, the dielectric varies in thickness directly with the tension, and the whole is clamped between brass plates. The dielectric plates in the higher-tension portion are made larger than those in the lower-tension portion to avoid sparking over the surface, and the entire instrument is suspended in oil for the same reason. The accuracy of the apparatus made has been tested by careful experiments. The measuring instruments used were calibrated at the time of the experiments by comparison with a Kelvin standard balance, and the P.D.'s for the high-tension instrument were obtained by means of a transformer of known ratio. This ratio was determined at a low P.D., and found to be 55·42 and assumed constant; thus the actual voltage

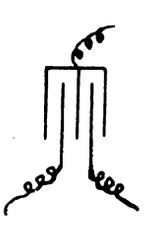

Fig. 4

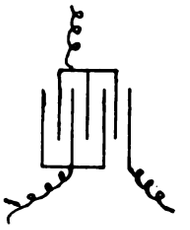

Fig. 5

in all cases given below is that measured on the primary multiplied by 55·42.

RESULTS OF EXPERIMENTS.

Low-Tension Instrument.

The ratios given above in all cases differ by less than 1 per cent. from their mean value, and in most cases agree much more closely. Any variations that exist are well within the limits of experimental error. It is hoped that this device may be of considerable practical utility, not only in simplifying the construction of high-tension voltmeters, but in laboratory and experimental work, where it frequently happens that measurements of potential have to be made with voltmeters, the best parts of whose scales are too low. The invention has been provisionally protected.

RADIUM AND OTHER RADIOACTIVE SUBSTANCES WITH A CONSIDERATION OF PHOSPHORESCENT AND FLUORESCENT SUBSTANCES. THE PROPERTIES AND APPLICATIONS OF SELENIUM AND THE TREATMENT OF DISEASE BY THE ULTRA-VIOLET LIGHT.*

BY WILLIAM J. HAMMER.

(Continued from page 357.)

With the relay it is placed in the bottom of the buoy and arranged to be absolutely waterproof. When I was in Berlin last August, one of these buoys had been in operation since the previous October, turning the light on and off every night and morning; and Mr. Ruhmer has recently written me that it is still operating successfully, as are others which he has placed near Hamburg and in the Baltic Sea. Mr. Ruhmer has also constructed an apparatus employing the selenium cell to which he has given the name "photographophone," which is one of the most remarkable pieces of scientific apparatus that it has ever been my pleasure to see. Figs. 25, 26, and 27 illustrate the general construction of the apparatus, which I shall further illustrate by accompanying lantern slides. In Fig. 28 the apparatus is shown diagrammatically, and in Fig. 27 the inventor is shown listening to the photographophone reproducing speech and music. It consists of a box containing a gelatine or celluloid film, such as employed in moving picture machines, which is driven at high speed by means of an electric motor. In the front face of the box is set a cylindrical lens about the size of one's little finger. A short distance away from the box is placed an arc lamp and a telephone. Words spoken or sung into the telephone superimpose the waves in the telephone circuit upon the current flowing in the arc light circuit, and cause a corresponding variation in the light of the arc. The rays from the arc lamp pass through the cylindrical lens already referred to, and are caused to fall in sharp white lines on the moving sensitive film. This film, upon being taken out of the box and developed, shows a series of perpendicular striations parallel to one another, which are really a photographic record of the sound waves originally entering the telephone transmitter. Where the striations are fine and close together, the pitch is high, but where they are broader and farther apart the pitch is low. Strips of the films or photograms are shown in Fig. 29. The developed film is next placed back into the box, and the motor again started. The arc lamp remains in its original position, but burns steadily as the telephone is not operated. The rays from the arc lamp passing through the lens are therefore quite uniform, and the moving gelatine strip acts as a screen to cut off these rays, allowing the light intermittently to fall upon the selenium cell at the back of the box, producing a variation in its resistance and a corresponding effect in the telephone receivers connected thereto. A battery is also interpolated in the circuit with the selenium cells and the telephones. By holding these telephones to the ear, the reproduction of the sound is perfect, as I can vouch for from personal experience with the apparatus. Mr. Ruhmer contemplates utilising this photographophone as a receiving instrument with its wireless telephone system, in which he employs a beam of light, as already described. Mr. Shelford Bidwell has also made a device for producing pictures or writing at a distance by combining the properties of selenium with the chemical telegraph.

Various inventors have endeavoured to solve the problem of seeing what goes on at a distance by employing selenium. Among these are Perosino, Senlecq, De Paiva, Cary, Sawyer, Larroque, Nipkow, Gemmill, Liesegang, Heinzerling, Edison, Stern, Jan Szczepanik, Dussaud, Otto von Bronk, Von St. Schneider, Ayrton and Perry, Korn, and others, who have proposed various methods employing images thrown on ground glass or through a photograph negative, or upon mirrors swinging synchronously, by or using revolving perforated screens, for cutting off the

FIG. 27.—Mr. Ernest Ruhmer Listening to his Photographophone.

beams of light, multiple selenium cells which would be affected by high lights and low lights of the original picture, etc., these devices affecting some method of illumination at the receiving end or producing an electro-chemical action such as is produced by the usual chemical telegraph system, or controlling an electro-pantograph system such as Gray's telautograph. These various inventions have been termed the telescope, telephote, telectroscope, and the telephotograph. But these devices have thus far reached little further than descriptive matter, drawings, and crude experiments. Various people have suggested the use of selenium cells for photometric purposes, and it is interesting to note that Mr. Latimer Clark suggested this application the evening in

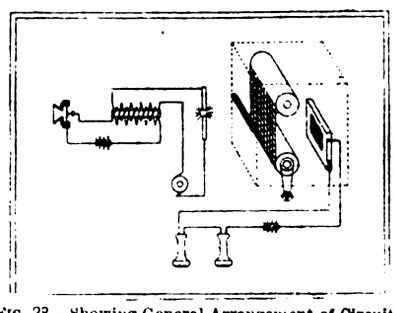

FIG. 28.—Showing General Arrangement of Circuits of Ruhmer's Photographophone

which Mr. Willoughby-Smith first brought to public notice the phenomena of variation in resistance of selenium when exposed to light, to which I have already referred. Mr. Fritts has suggested making a form of photometer which would be sensitive to lights of different colour, as well as of varying candle-power, by employing as a film on the surface of his cell a gold foil which transmits green rays, a silver foil the blue rays, and so on, and suggests that a solid transparent conducting film which would transmit all of the rays would be far better and thus remove the colour stumbling block in photometric work. Sir William Crookes has constructed an exceedingly interesting type of radiometer, in which he has coated the revolving vanes on one side with selenium, and on the other with chromic acid. He found that the white light from a sperm candle repelled

* A lecture delivered at a meeting of the American Institute of Electrical Engineers and the American Electrochemical Society, New York, April 17, 1903.

Digitized by Google

the selenium, while the yellower light of the wax candle repelled the chrome, thus indicating the relative absorptive powers of the different substances for rays of different refrangibility, resulting in mechanical motion; just as the same selective capacity operates in photography as

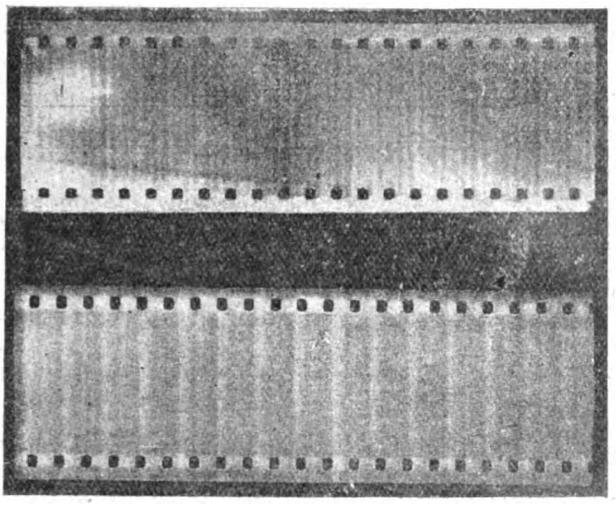

FIG. 29.—Photogram as used in Ruhmer's Photographophone (High-Pitch Tones above, Low-Pitch below).

chemical action. In 1891 Prof. Barnard, of Lick Observatory, employed a selenium cell as a device for automatically detecting comets, and Minchin has employed the selenium cell quite extensively in his astronomical investigations. In Fig. 30 is shown a curve which Mr. Ruhmer recently sent me which shows some

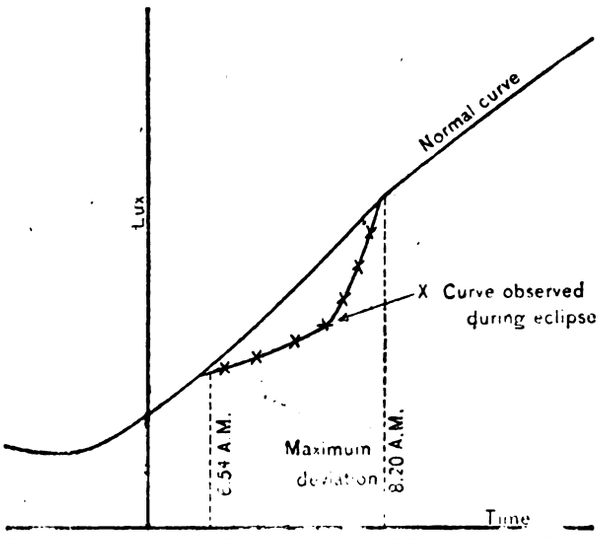

FIG. 30.—Curve taken with Ruhmer Cell during Eclipse, Oct. 31, 1902.

observations made by means of his selenium cell during an eclipse, these being the only observations which anyone was enabled to make at that time on account of stormy weather. Mr. Ruhmer has prepared an interesting paper bearing on this and other applications of the selenium cell to meteorology. He made his observations on Oct. 31, 1902.

Selenium is found in Vesuvian lava, and in natural sulphur as a sulphur selenide in the Lispari Islands. It is also found in Norway and other iron pyrites. It occurs in meteoric iron and in such rare metals as eucarite as a selenide of silver and copper in Sweden and Chili; crookesite, a selenide of copper and thallium with a little silver, from Norway; as clausthalite, a selenide of lead in the Hartz Mountains, from Zinken and Clausthal, in Inverg, Rheinberg, Saxony, Rio Tinto, Spain, Mendoza, South America; as riolite at Culebras, Mexico; as Lehrbachite, a selenide of mercury and lead from the Hartz Mountains; as zorgite, a selenide of copper and lead from Glasbach in the Hartz Mountains. Selenium, although widely distributed over the globe, occurs only in small quantities and in some instances is found in native state. Selenium is placed among the rare metals. Chemically pure crystalline selenium costs about 1dol. per gramme; and the ordinary commercial article about 10 cents per gramme. The

bibliography of selenium is quite extensive. Those interested in the subject will find an excellent paper by Mr. A. P Saunders in the *Journal of Chemistry* for June, 1900. The paper contains many references, and is entitled "Allotropic Forms of Selenium."

(To be continued.)

PRODUCTION OF CHLORINE AND CAUSTIC ALKALI.

Most of the larger paper and pulp mills have begun to instal in recent years electrolytic plants for the production of bleaching powders for their own use. All of them use diaphragm processes, but the construction of the cell varies in different plants. A patent for a new diaphragm has been granted in the States to A. B. Larihar, and assigned to the Penobscot Fibre Company, which has conducted a number of experiments with the process. The special feature of this new cell, as described in the *Electrical World*, is the cathode, which is of peculiar construction. It consists of a grating forming a complete enclosure, constituting the side walls of the cell. This grating is in sections, forming the four sides of a parallelogram and secured together at the corners by posts of angle iron. The polygonal enclosure thus formed serves not merely as the cathode, but possesses sufficient rigidity to act as the wall of the cell, supporting itself and the diaphragm which is stretched upon it, and also the cover of the cell from which the anodes depend. The grating which composes the cathode consists of a series of vertical bars or slats of soft steel. The slats are spaced uniformly apart, so that a lamellar cathode is formed which divides the solution into a great number of films which pass from the diaphragm out through the cathode into the receptacle which surrounds the cathode. The floor of the cell is formed of Portland cement. The diaphragm consists of asbestos paper, several thicknesses of which are placed around the walls of the cell so as to break joint with each other, each layer forming a lap-joint with itself. The anodes consist of a series of graphitised carbon slabs. Brine is supplied to the anterior of the cell, which represents the anodic compartment. The caustic soda solution escapes from the outside reservoir through an overflow pipe, which is adjustable, so that the surface level of the liquid in the outside reservoir may be changed at will. By maintaining the inside level (anode compartment) slightly above the outside level, it is possible to counteract the tendency of the O H ions to come over from the cathodic into the anodic compartment and there cause trouble. In this the inventor applies the old method used by Le Sueur in his early pioneer work.

APPOINTMENTS VACANT.

Junior Engineer, Dundee Town Council.

Shift Engineer, Taunton Corporation, £100, 28th inst.

Assistant Resident Engineer, Middlesex Hospital, W., 23s., 21st inst.

Chief Tramways Officer, London County Council, £1,500, 28th inst.

NEW COMPANIES REGISTERED.

British Electric Calibrated Fuse Company, Limited.—Capital, £3,000. Objects: to adopt a certain agreement, and to carry on the business of manufacturers of and dealers in electrical accessories and appliances, electricians, electrical engineers and contractors, manufacturers of rubber and rubber goods, etc.

Electro Post Railway Company, Limited (78,489).—Capital, £100. Objects: to construct, repair, maintain, and operate installations, cables, wires, and other works of every kind for the generation, supply, distribution, and employment of electricity for motive power, lighting, heating, or other purposes.

Glasgow Electric Crane and Hoist Company, Limited.—Capital, £100,000. Objects: to acquire patents and patent rights for Great Britain and Ireland granted to the Benrather Maschinenfabrik Actien-Gesellschaft, and the exclusive right for a period of 10 years to sell in Germany machinery in accordance with these patents, and to carry on in the United Kingdom, Germany, and elsewhere the business of, makers of, and dealers in electrical and hydraulic cranes, hoists, lifts, etc.

QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

QUESTIONS.

619. How can the pressure and vacuum gauges be calibrated in the station without the use of standard instruments?—W. F. F.

620. With a shunt-wound motor it is found that the no-volt release on the starting switch takes an appreciable time to act after the current is broken to motor. If the motor is heavily loaded when current is broken, it has stopped running before the switch arm is released. But if main current is left on, and circuit broken at field shunt connection or starter, the no-volt release immediately releases switch arm, but the motor takes much longer to stop than when main current was broken. Explain this fully.—C. W. G.

ANSWERS.

Question No. 611.—Two 300-kw. alternators running in parallel and fully loaded, when a short-circuit occurs on one of the high-tension feeders. After the feeder is made dead, the two machines are put in parallel again on the 'bus bars (with no load). Would it be safe to switch in the remaining (say six feeders one by one?

Answer to No. 611 (*awarded* 7*s.* 6*d.*).—If the load consists of lighting and small motors, no harm could be done by switching in the feeders one by one. If, however, there are several large motors with starting resistances in circuit, and the switches had not been taken out or the resistances put back into circuit at the time the current was switched off at the station, it would be risky, as you would possibly blow the fuses of these motors. If the fuses were not the proper size—*i.e.*, too large—then you might do other damage. It must be remembered that there is no automatic release on alternating-current starting switches. Also (in any case) if there is likely to be a weak spot in the insulation of transformers or cables, the sudden high pressure when inserting the switches might find the weak spot.

Your machines should easily stand the load brought on by each feeder, although care should be taken, together with a little forethought. What I should do would be to first take out all feeder switches, then parallel the two machines and switch on to the 'bus bars. You have some idea of the load on each feeder, therefore put in as many switches one by one that will give No. 1 machine its load, then put in the remaining switches one by one, varying your exciting current with the increased load in both cases.

If there was a 1,000-kw., or even an 800-kw. set in the station and plenty of boiler power at the time, I should use this set, in which case you could have all your feeder switches in, including your machine switch, run your engine up to speed and gradually bring on your load with the exciting current. By doing this, your motors, as mentioned above, would start with the load without fear of doing any harm. Afterwards you could run your two 300-kw. sets in parallel with the 1,000-kw. set and give the two former their load, taking out the latter after doing so.—J. W. W.

Answer to No. 611 (*awarded* 7*s.* 6*d.*).—We assume from the question that the short-circuit occurring on the high-tension feeder blows the fuses of the two alternators, but is not sufficient to blow its own fuse, because "P. C. S." refers to the feeder being made dead after. Suppose the supply at the works was generated at a pressure of 2,000 volts, and delivered into sub-stations for transforming purposes by seven feeders, each feeder being connected

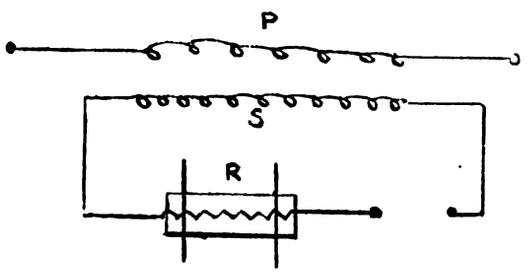
Digitized by Google

to distinct and separate networks, the two alternators would be producing at this pressure a total of 300 amperes, and the average load on the feeders would be about 44 amperes. No. 6 feeder produces a short-circuit, and the rush of current is sufficient to blow the machine fuses, which have already been carrying their full working current. The switches are now taken out and the machines re-fused and then paralleled in. Now the feeder switches can be closed one by one (except No. 6), but an interval of about 15 seconds should be allowed between each, as the rush of current due to self-induction on the insertion of each feeder would have time to die down. Care should be taken to keep the machine pressure considerably above the normal—say by 50 volts—before closing one of these circuits, and although this would not cure the "blinking" of the lights, it would prevent them from going down too low. Under the conditions stated, the total current would now be about 256 amperes, and this would give the machines more margin for taking the strain imposed upon them, especially when inserting the last two switches. But the feeders should be fused, so as to blow as soon as anything like a short occurs along their length. As it is important under ordinary conditions to get the consumers on as quickly as possible, it would be preferable to place one machine across the "dead" 'bus bars, close, say, three feeder switches, and then parallel in the second machine, after which the remaining feeders could be dealt with. By this means a part at least of the customers would only be in darkness for a short time.

With a good governing engine and a well-built alternator, and a cool head on the part of the switchboard operator, this could be done quite safely and without much loss of time.—MUNDY.

Answer to No. 611 (*awarded* 7*s.* 6*d.*).—The question in itself is very incomplete, no idea being given of the circumstances of working voltages and load. Under ordinary conditions the fuses on the short-circuited feeder should go first, but we will consider the latter part of the question only. It appears that the ordinary practice is that of running up on the feeders, and several conditions have to be known to give an answer which may be applicable to the system.

With high-tension alternating-current cables the type plays a large part, a concentric cable, for instance, having a far higher self-induction than a three-core cable; and again, the voltage has such a large effect, for with anything over about 3,000 the resonance of the cable has to be considered. The resonance of the feeder depends upon its length, and within certain limits—*i.e.*, a few miles, which distance, of course, depends upon the kind of cable used—nothing is felt, but beyond that the curve of resonance rises very sharp to a maximum, from whence it falls gradually as the cable lengthens, therefore giving two points of length on which inside lengths suffer from the resonance. The effect of this will be that when suddenly switched on it will cause an abnormal rise in voltage for the instant, which may prove very detrimental to the cable's insulation.



However, another very important factor is that of the nature of the load. This is generally, and should be, known to the person who would switch on, and a load consisting of induction motor, transformers, etc., which would, if left switched on, cause a large self-induction, would not allow of being suddenly switched on. Several good methods are employed to overcome this self-induction on such circuits and prevent distortion by heavy loads, and one used on a high tension network system may be mentioned. A primary transformer winding is connected by switching in first in the main circuit, which allows a small current only to flow, a secondary winding, S, is in circuit with a water resistance, R, which is gradually cut out, when the secondary coil gradually overcomes the self-induction in the primary, and raising the primary current until its maximum is reached, when it is short-circuited, and the feeder is directly connected.—S. F. RICKETTS.

Answer to No. 611 (*awarded* 5*s.*).—This question resolves itself into a consideration of the advisability of switching the feeders in circuit, as indicated, under various conditions, as regards the machines and apparatus in use at the time, which obtain their required energy from the alternators in parallel. Also, in the question there will be involved a counter-action or series of counter-actions in the alternators themselves which will require consideration. In order to deal with this subject in a complete and proper manner, and with entirety, it will be the best course of action to generalise each case, which under ordinary conditions might exist, as complete in itself. In the first place, if, on the immediate cut-off of the supply from the feeders, and therefore from the consumers' premises, the switches of every motor are opened so as to isolate them and disconnect them entirely, then, in the event of an immediate re-supply, whatever the type of motor and which feeder supplies them with energy, it will be perfectly safe to switch in the feeders one by one in circuit. In the case of incandescent lamps, whether the lamps are switched out of circuit or otherwise, we have a case which stands alone—different entirely to motors—and if the feeders supplied energy to lamps of the above character and not to motors, then no disastrous effects would ensue from switching the feeders in circuit. That the above is the case can easily be seen, since both examples taken are only every-day examples; the first producing no effect, the second, being that of the lamps, having the full pressure applied at the terminals immediately on the resumption of the supply—a case occurring every time an incandescent lamp is used. In the following cases, however, different conditions exist which require consideration. The case of the asynchronous motor will be taken first. It might happen that the attendant of any such motor, fed from the mains, might fail to switch off such a motor from the system. The effect of switching an induction motor with short-circuited rotor straight on to the mains is well known, especially if the motor be of a large output in proportion to the capacity of the generators. What would really occur in the case of induction motors, whether the rotors be of the short-circuited or wound type, is somewhat analogous to the above. At the instant of resumption of supply, if the motors are not switched off, a large overdraft of current takes place in the system. This will lower, for the time being, the power factor, and produce a lag in the current, and the effect of such upon the alternator coils might be unlooked for, and it might produce a tendency to unequally divide the work between the two alternators. It will also disarrange the whole system supplied by the two alternators, and produce objectionable effects in the working thereof. The motors in themselves might suffer very little damage. With synchronous motors a different set of conditions exist. As is well known, motors of such a type will not start without some auxiliary device is brought into action, and so in this particular case no start would be obtained from the motor, and it would have the winding of its armature placed across the mains, subject to the force of the full pressure, without any back pressure generated by motor reacting.

In the above discussion it has been assumed the effect of any of the above actions on the transformers used is negligible, since a static transformer is an automatically-regulated machine, self-regulating the current traversing its coils according to the demand for energy. If rotary converters or motor-generators be in use at different points of the system, and are fed by the mentioned feeders, their case may be similar to either of the above cases dealing with motors, according to the type used. Reviewing the above, it will be seen that safety lies in the knowledge of the reliability of the attendants, and also to the extent of the experience of the attendants.—G. W. B.

Question No. 612.—Are shunt motors of the same brake horse-power ever wound to give different starting torques? If so, what is the practical maximum torque per brake horse-power in pounds-feet that can be obtained?

Best Answer to No. 612 (*awarded* 10*s.*).—The starting torque per brake horse-power of a shunt motor is inversely proportional to the speed for which the machine is designed. The starting torque may be taken as equal to the normal running torque (assuming no increase of current at starting), and since the power developed by a motor is simply proportional to the product of its torque by its speed, the starting torque per brake horse-power is inversely proportional to the speed. By increasing the dimensions of the motor, and so reducing its speed for a given brake horse-power, the torque per brake horse-power can be increased indefinitely. Thus, a 1,000-revolution motor will develop $\frac{33{,}000}{2 \times \pi \times 1{,}000} = 5\,24$ pound-feet (or pounds pull exerted at a diameter of 2ft.) per brake horse-power, whilst a motor running at 100 revolutions will develop 10 times as much torque.

Looking at the matter in another way, the torque of a motor may be considered as proportional to the product of flux × conductors on armature × current in armature, and as a motor designed for a given voltage carries a fixed current per brake horse-power in its armature (neglecting small differences in efficiency), the torque per brake horse-power depends simply on the product of flux × conductors. As the value of this product is inversely proportional to the speed of the motor, it is clear that the torque per brake horse-power is inversely proportional to the speed for which the machine is designed. Of course, by allowing the current at starting to increase, the total starting torque can be increased considerably, and, in a way, this may be considered as increasing the starting torque per "brake horse-power of rated load." An increase of at least 100 per cent. can usually be obtained in this way before the armature reaction becomes great enough to overpower the shunt excitation.—Q.

Answer to No. 612 (*awarded* 5*s.*).—Shunt motors vary considerably in the torque, or turning moment of their armatures. A cheaply-made machine running at a high speed will necessarily have a smaller torque than a heavily-built one, of equal horse-power, running at a lower speed. The torque, or turning moment, should be carefully distinguished from the pull given by the conductors on the armature.

$$\text{Torque} = \frac{C \times N \times W}{(8\,5 \times 10^8)};$$

where C = current in amperes through armature;
N = total number of lines through field;
W = total number of conductors on periphery (or in slots) of core;
$(8{\cdot}5 \times 10^8)$ = a constant to give the torque in pounds-feet.

The torque is the whole effort of the conductors on the armature multiplied by the radius of the armature; if answer is required in pounds-feet, radius must also be taken in feet. There are then, by the equation, three methods by which the torque at starting may be increased. By allowing more current to flow; this is usually limited by the starting arrangements to the full-load current, so that alteration in the winding under these circumstances will not affect the question. By increasing the number of lines of force through the armature; this may be done to a certain extent by saturating the magnets above the most economical limit, or by increasing the size of the machine. The third method of increasing the number of conductors on the armature generally means a larger and more expensive motor. For shunt motors of from 5 h.p. to 15 h.p. a starting torque with full-load current of from four to six pounds-feet per horse-power is a fair average. Where shunt motors are in use it is very often the practice to put in heavy fuses, and thus get a large current when starting. A much better way, though not generally done, is to have a cumulative series winding that may be cut out when the motor has attained its full speed. With this arrangement we get the advantage of the greater torque of the series motor at starting and afterwards the regulating properties of the shunt machine.—M. M.

Answer to No. 612 (*awarded* 5*s.*).—Shunt-wound motors of the same brake horse-power only give different starting torques when they are wound for various speeds. Let $C_a \times E_a$ (total useful watts) represent the useful available power at the pulley of motor—*i.e.*, C × E = watts—supplied to motor minus losses in armature and shunt circuit due to eddy currents, hysteresis, and friction. Then $C_a \times E_a$ is the brake horse-power or useful power at the pulley.

Let T = torque or force in pounds-feet.

$$\therefore \frac{C_a \times E_a \times 33{,}000}{N \times 2\,\pi \times 746} = T,$$

where 33,000 = unit of power, and $N \times 2\,\pi$ = circular velocity, and 746 = the electrical horse-power.

Example.—$C_a = 10$, $E_a = 500$, $N = 500$.

Then $$T = \frac{10 \times 500 \times 33{,}000}{500 \times 2\,\pi \times 746} = 70{\cdot}4 \text{ pounds-feet.}$$

Then $$\text{B.H.P.} = \frac{T \times 2\,\pi \times N}{33{,}000}.$$

Had the speed been 1,000 revolutions at the same brake horse-power, the turning power would have been less by half, or the one at 500 revolutions would have twice the turning power than the one at 1,000 revolutions. The slow-speed motors, having a higher starting torque, must necessarily be much larger in construction, and involves increased electrical losses which reduces the efficiency. The increase in size also increases the cost of manufacture. It will therefore be seen that there is no fixed constant for the practical maximum torque per brake horse-power for motors of the same brake horse-power, since the torque various with the speed.—J. W. W.

OLDHAM ELECTRICITY UNDERTAKING.

The report of Mr. Arthur Andrew, the superintendent, on the work of the above undertaking for the year ended March 25 last shows the following results:

The expenditure on capital account during the year has amounted to £108,573. 6s. 10d.

The gross revenue for the year amounts to	£26,278	15	2
And the gross expenditure to.....	13,666	13	8
The balance carried to net revenue account being	12,612	1	6
The interest on loans amounts to £4,295. 12s. 2d., and sinking fund instalments to £2 987. 17s. 2d.....	7,283	9	4
The net profit for the year being	5,328	12	2
The credit balance brought forward from the previous year was.....	832	7	2
Leaving a credit balance to carry forward to next year's account of	6,160	19	4

The receipts for energy supplied for ordinary purposes are £538. 1s. more than in the previous year. The amount received for current supplied for tramway traction is £14,741. 7s. 3d., against £2,641. 10s. 9d. in the previous year. The amount received for rental of meters and indicators also shows an increase of £25. 15s 6d. The amount of interest accrued to the reserve fund during the year is £190. 7s. 3d. The total amount standing to the credit of this fund on March 25 was £4,968. 10s. 3d. The amount of energy generated has been 3,189,849 units, of which 2,869,312 units have been sold, being increases over the previous year of 1,947,279 units and 1,827,257 units respectively. The number of lights supplied on March 25 last, equivalent to 8 c.p., was 54,154, being an increase during the year of 8,765. The number of consumers added has been 80, and additional meters fixed, 80, the number of consumers on March 25 being 638, and the total number of meters fixed 692. The number of demand indicators fixed on consumers' premises on March 25 was 389. The maximum demand (exclusive of traction) was on Dec. 19, 1902, the load at the station being indicated at 768 kw., as compared with 765 kw. in the previous year, showing an increase of 3 kw. The greatest quantity supplied in 24 hours for lighting was on Jan. 10, 1903—viz., 5,817 units, against 5,207 units last year, an increase of 610 units. The greatest quantity supplied in 24 hours for traction was on March 14—viz., 10,341 units, as compared with 1,840 units last year, an increase of 8,501 units. The supply mains have been extended a distance of 2,286 yards during the year. The total length of mains laid on March 25 last was 22,154 yards. An alteration in the price charged to large and long-hour consumers was made from Dec. 24 last, by which the minimum charge was reduced from 2d. to 1½d. per unit. The price charged for traction purposes was reduced from 2d. to 1⅜d. per unit from June 25, 1902, and further reduced to 1½d. per unit from Dec. 24 last. The erection of the new station at Greenhill was so far completed as to permit of the plant being brought into use in August, 1902. The engines and dynamos installed in this station comprise two of 600 h.p. each and four of 1,200 h.p. each, and the steam power is provided by eight dry-back marine and three Climax boilers, having a total evaporative capacity of 167,000lb. of water per hour. The generating capacity of the Gas-street station remains the same as last year—viz., 2,480 h.p.

TRADE NOTICES AND NOVELTIES.

Motors and Generators.

We have received from the Rhodes Electrical Manufacturing Company, 70 and 71, Bishopsgate-street Within, London, E.C., a copy of their latest catalogue of motors and generators. This firm claim to supply a high-class article at a reasonable price, and since they devote their attention exclusively to the manufacture of one type of machine, the claim should be justified. Some excellent designs of motors are illustrated in the catalogue, ranging in capacity from ½ b.h.p. to 40 b.h.p. for standard voltages of 115, 230, and 460, and generators ranging in output from 1 kw. to 24 kw. Prices and particulars, including a full specification of the construction, are given. With reference to the latter, some points are noteworthy. For example, the firm have a special and exclusive design of brush rocker, provided with an arm which extends over to the centre of the commutator, thereby enabling the use of a radial spindle for supporting the brush-holder, the latter being exceptionally rigid, whereby all vibration on the brush is eliminated. In general appearance and finish these machines leave nothing to be desired.

Switchgear.

From Messrs. Bray, Markham, and Reiss, Limited, Blackhorse-lane, Walthamstow, N.E., we have recently received a copy of their new price-list. The firm make a speciality of electrical switchgear, and the list in question contains illustrations and descriptions of some very serviceable-looking B.M.R. double-pole switches and ratchet type motor starters.

New Hack Saw.

Messrs. Beanland, Perkin, and Co., School Close Works, Leeds, have just introduced a new type of double hack saw. This saw is constructed on novel lines, having two saws working alternate strokes, and reducing by one-half the time required for cutting through girders, etc. The price of the machine, including six blades, is £15.

G.E.C. Manufactures.

"Witton" continuous-current dynamos are dealt with in list (No. P, 1,039) just issued by the General Electric Company, Limited, 71, Queen Victoria-street, London, E.C. This is a "sister" list to the "Witton" continuous-current motor catalogue published some little time back. It includes a very clear concise specification of the firm's dynamos, of which they make two types—viz., the open protected pattern for small outputs and the open multipolar pattern for large outputs. These machines have been standardised in a large variety of sizes for 110, 220, and 440 volts, and also for 140 volts in connection with accumulator charging. The tables of which this list largely consists are a model of lucidity. Considerable trouble has been taken to set out in detail weights, shipping dimensions, and linear dimensions of the various sizes. A table of spare parts and accessories is included. Another list (No. E. 1,042) issued by the same firm contains some useful information with regard to the arc lamp carbons manufactured at Witton. These carbons are claimed to be equal, if not superior, to the best Continental makes. It appears from the list that three qualities are supplied—viz., a "standard" quality, a "special" quality, and a third quality specially recommended for enclosed arc lamps.

From the General Electric Company, Limited, we have also a copy of their new pamphlet dealing with the Aron electricity meter. This meter has been passed by the Board of Trade for use on both continuous and alternating current circuits, and one of the principal advantages claimed is that it is a true watt-hour meter, and records direct in Board of Trade units. Lastly, a copy of their leaflet No. M. 1,041, which gives particulars of Milner's patent speed indicator. This indicator is so made as to be capable of running accurately in either direction without any additional adjustment. Extreme simplicity is the principal feature of its design.

Fuller-Macleod Specialities.

We have received from Messrs. Fuller, Macleod, and Co., Limited, 9, Red Lion-court, Cannon-street, London, E.C., a budget of their new lists. The principal of these deals with telephones, telephone switchboards, and accessories. A noteworthy feature in connection with this list is the general excellence of the illustrations. Each piece of apparatus shown has a reference number, the corresponding number being set opposite a concise description and the price of the apparatus in the index. Another of the lists includes particulars and prices of "Lux" incandescent lamps. List S is devoted to plain, fancy, and cut-glass shades for incandescent lamps; while a line in ceiling roses, small motors for direct and alternating current, and continuous-current electric motors for power transmission are dealt with respectively in the remaining lists. Three types of machine are included in the last-mentioned—viz., semi-enclosed, enclosed ventilated, and enclosed. A full specification of their construction is given, also tabulated data for the different machines.

LEGAL INTELLIGENCE.

MARCONI'S WIRELESS TELEGRAPH.

On Wednesday in the Vacation Court Mr. Justice Bucknill heard a motion *in re* Marconi's Wireless Telegraph Company, Limited.

Mr. Gover, for the company, said this was an application for an order of the Court granting leave to rectify an omission to comply with Section 7 of the Companies Act of 1900. It was a case in which, through inadvertence, there had been a failure to file a memorandum of agreement to transfer shares in the Marconi Company. In order that the requirements of the Acts of 1867 and 1900 might be complied with, it was necessary that notice of the agreement should be given within a month to the registrar so that it might be filed. In March last the company agreed to transfer to a Mr. Saunders a certain number of fully-paid shares in the Marconi Company in return for shares which Mr. Saunders was to transfer in the Marconi International Marine Communication Company, Limited. The agreement was verbal, the transfers were duly executed, and the shares allotted. The difficulty had arisen owing to the requirements of the Act having been overlooked through inadvertence both by the secretary of the Company and by Mr. Saunders.

His Lordship made the order asked.

ANGLO-AMERICAN ALUMINIUM COMPANY.

In the Vacation Court on Wednesday before Mr. Justice Bucknill, **Mr. G. Campbell,** for the company, moved that an order made by Mr. Justice Walton last week in the case of Hamilton *v.* the Anglo-American Aluminium Company, Limited, appointing a Mr. Nelson receiver on the part of debenture holders, should be rescinded, and that, instead of Mr. Nelson, Mr. Newitt should be appointed.

His Lordship asked to have further affidavits delivered to him during the week, and said that he would give judgment on Wednesday next.

COMPANIES' MEETINGS AND REPORTS.

SIR HIRAM MAXIM ELECTRICAL AND ENGINEERING.

The annual meeting of the shareholders in this Company was held at 44, Gillingham-street, Pimlico, on Monday, under the presidency of Mr. Jules De Merry.

The **Chairman,** in moving the adoption of the report, said that since he presided over their meeting about a year ago the Company had passed through many hard struggles, and had encountered, but he was glad to say had surmounted, many great difficulties. All differences, however, were now at an end, and the days of litigation with the lamp company were over. As to the volume of the business done, in 1900 they had only £14,636 to report, and in 1901 the figures were £35,097. From the date of the last balance-sheet up to that day the contracting department alone showed that they had taken over £105,000 worth of contracts. The field of operations was practically unlimited. They began about three years ago by taking from contractors small orders in connection with the latter's contracts. This was followed by making a speciality of all steam accessories for electrical power stations, the Company taking big contracts themselves in this special line of business. They had made arrangements which enabled them to contract for the whole of the erection and complete equipment of electrical power stations. Lately they had extended the scope of their civil engineering and contracting department. They had been entrusted by the Chiswick Council with their new sewerage scheme, and by the Corporation of Chatham with the extension of their pier and landing stage. At Manchester their men were divided into three shifts, each working eight hours a day. The Company's part of the contract was finished at the time, and the chairman of the Lighting Committee thanked them for their work, while Prof. Kennedy acknowledged their energy by recommending the Company for many other contracts which had since been given to them. They had a similar experience at Grove-road power station in London. Lately they were entrusted by the Westinghouse Company with part of their contract for the Naval Cadet College in the Isle of Wight, and the work was finished exactly at the time required. They were also on the point of starting a boiler department. They had become contractors to the Admiralty, the War Office, the India Office, and the Crown Agents to the Colonies, and an important share of the supply to these various services could be relied upon. In addition to their incandescent lamp, they had successfully turned their attention to a new arc lamp. Sir Hiram Maxim was devoted to their interests, and he was now spending large sums to perfect a certain invention from which the Company would probably derive the greatest benefit. All things considered, he thought that their prospects were exceedingly bright. He sympathised with the shareholders in the fact that there was no dividend, but the Company had had to lay the foundation of and to create a growing concern.

Sir Hiram Maxim seconded the motion, and said: Now that my health has improved, I hope to remain in England 10 months in the year. In regard to the new work which you have in hand, you can look at my past. On several occasions I have thought out very important inventions that had a lot of money in them, and various parties at different times, in America and in England, have made large sums of money from these. I have thought out another invention—something that perhaps has more direct money in it than anything else I have ever done, not excepting the automatic gun. I found, on speaking to my friends about this invention, that if I

Digitized by Google

wanted any money to exploit it any amount would be given me; but I am not accepting a single penny. I am putting in every penny myself to prove the invention, and when it is proved I propose to make arrangements—I have already made a proposition to the Company. I am bringing out this invention very largely to put this Company on a paying basis. and, as a proof of my belief in this invention, I am putting thousands of pounds of my own money in it, and one of the considerations of the agreement is that I have a right within a few years after this invention is brought out of buying a large block of the Company's shares at par. That is the consideration I get. I think that in this way I shall get a very fair return, because the invention I am working on at the present time will bring in a very considerable amount of money. The nature of the invention is such that I cannot speak of it at the present moment. I am advised to say nothing about it until the patents are secured everywhere, because when it is once known, there will be hundreds of others who will try to get round your patents. I advise you all, no matter how much you have been discouraged in the past, to stick to the shares, or if you wish to sell them, perhaps I shall be able to buy all you have got within a few months.

The motion was adopted, and a resolution was also passed for increasing the capital to £190,000 by the creation of 15,000 ordinary hares of £1 each.

CHLORIDE ELECTRICAL STORAGE.

The report of the directors for the year ending June 30, 1903, states that the balance-sheet shows a trading profit for the financial year of £20,756. 12s. 10d. After deducting directors' and auditors' fees (to June, 1902), debenture interest, depreciation, provision for bad debts, and interim dividend on preference shares, the available balance for the year is £6,030. 4s. 4d., to which must be added £5 802. 4s 8d. brought forward from last year, making a disposable balance of £11,832. 9s. The directors propose the payment of a dividend of 6 per cent. on the preference shares for the financial year, less interim dividend already paid, and a dividend of 8 per cent. on the ordinary shares, free of income tax, together amounting to £4,520, and to carry forward the balance, £7.312. 9s. During the year under review the Electric Storage Battery Company of Philadelphia, U.S.A., with which the Company has always maintained close relations, acquired, by purchase of shares, a very large interest in the Company. The directors accordingly elected Mr. Herbert Lloyd (president of the Electric Storage Battery Company), Mr. John R. Williams, Mr. Robert E. Lloyd, and Mr. J. De Berniere Smith as directors to fill the vacant places on the Board, in order that this interest might be adequately represented. Under the circumstances it is advisable that its reconstitution be reviewed and determined by the shareholders.

CONTRACTS FOR ELECTRICAL SUPPLIES.

Macao.—The Colonial Office at Lisbon invite tenders for the electric lighting of Macao. Tenders by Oct. 21.

Lisbon.—The Public Works Department require tenders for the public electric lighting of Macao. Tenders by Oct. 21.

Paris.—The Posts and Telegraph Department, 103 Rue de Grenelle, require tenders for two lots of electric wire. Tenders by Oct. 1.

Bucharest.—The Government Railways require tenders for the installation of electric lighting and plant for their workshops. Tenders by Oct. 10.

Pietermaritzburg.—Tenders are invited by the Natal Government Railways Electrical Department for additional plant for the power station at Pietermaritzburg.

Transvaal Colony.—The Chairman of the Tender Board, Pretoria, requires tenders for installing and working the electric lighting of Potchefstrom for about five years. Tenders by Oct. 30.

Dublin.—The Port and Docks Board invite tenders for the supply of a 100-ton electric crane. Specification can be obtained at the office of the engineer to the Board, Mr. John P. Griffith, M.I.C.E., Eastwall, Dublin. Tenders by Oct. 5.

Blackpool.—The Corporation invite tenders for the supply of arc lamp carbons for the ensuing year. Specification, etc., may be obtained on application to Mr. Charles Furness, borough electrical and tramway engineer, Electricity Works, Blackpool.

Shanghai.—The French Colony propose to instal motor-propelled tramways. Tenders may be sent by Oct. 31, 1903, to Secrétariat de la Municipalité Française de Shanghai. Particulars may be obtained from l'Office National du Commerce Extérieur, Rue Feydeau, 3, Paris.

East Barnet.—The Urban District Council will receive proposals for carrying out the provisions of their electric lighting order within the Council's district. Further particulars upon application to Mr. Henry York, the Council's surveyor, Council Offices, Station-road, New Barnet.

Rochdale.—The Guardians invite tenders for certain new underground cables and switchboard alterations and additions required at the workhouse, Dearnley. Specifications, etc., may be obtained from Messrs. Shepherd and Watney, Greek-street-chambers, Leeds. Tenders by 26th inst.

Russia.—The Russian Minister of the Interior has sanctioned a plan for the reconstruction of three lines of municipal tramways—namely, those in Newsky, Sadovaïa, and Wassiliostrow districts. Each car is to provide for two classes of travellers, and will accommodate 52 persons.

Utrecht.—The Town Council will receive tenders for supply and erection of a central electric establishment for lighting, power supply, and working tramways. Contract, conditions, etc., to be obtained at the "Gemeente Secretaire" of Utrecht, on payment of 5fl. (8s. 4d.). Tenders by Oct. 1.

Swindon.—The Corporation invite tenders for erection at Swindon, Wilts, of car depot stores, repair shops, etc. Specifications, etc., may be seen at the office of Messrs. Lacey and Sillar, 2, Queen Anne's-gate, Westminster. Tenders to Mr. Robert Hilton, town clerk, Town Hall, Swindon, by 23rd inst.

Brighton.—The Town Council invite tenders for the (1) supply of steel girder tramrails, fishplates, etc.; (2) tramcars; (3) points and crossings and other fittings. Specifications, etc., may be obtained from Mr. Francis J. Tillstone, town clerk, Town Hall, Brighton Tenders by 10.30 a.m. on Oct. 5.

London, W.—The Commissioners of H.M. Works and Public Buildings invite tenders for alterations and additions to Ealing telephone exchange. Drawings, etc., may be seen on application to Mr. J. Wager. Tenders to the Secretary, H.M. Office of Works, etc., Storey's-gate, London, S.W., before 12 noon on 29th inst.

Johannesburg.—The Municipality require tenders for gas generating plant or for steam generating plant and for gas motors or steam motors, with electric generators and accessories. Particulars may be obtained from the Town Clerk, Johannesburg, or from Messrs. Mordey and Dawbarn, 82, Victoria-street. Tenders by Oct. 19.

Launceston (Tasmania).—The Mayor and Aldermen invite tenders for the supply of 500 or more electric meters. Particulars may be obtained on application to Mr. William Corin, city electrical engineer, Launceston, Tasmania, or to Messrs. John Terry and Co., 7, Great Winchester-street, London, E.C. Tenders by Sept. 28.

Bootle.—The Corporation invite tenders for the extension of the boiler-house at the electric light station, Pine-grove. Plans, etc., may be seen at the office of Mr. B. J. Wolfenden, A.M.I.C.E., borough engineer, on and after the 18th inst. Tenders to the Chairman of the Electric Power and Lighting Committee by the 30th inst.

Cienfuegos (Cuba).—The Municipal Authorities require tenders for the installation and working of electric lighting. They will pay an annual subsidy of 24,000 piastres for 150 arc lamps of 1,500 c.p. each and 350 incandescent lamps of 50 to 100 c.p. each for street lighting, and 16 to 25 lamps in public buildings. Tenders by 1 p.m. on Sept. 28.

Dundee.—The Town Council invite tenders for the relaying of distribution mains in the central area of the town. Specification, etc., may be had on application to Mr. H. Richardson, A.M.I.E.E., city electrical and tramways engineer, Dudhope-crescent-road, Dundee. Tenders to Mr. W. H. Blyth Martin, clerk to the Council, City Chambers, Dundee, not later than Sept. 30.

London, S.E.—The London County Council invite tenders for the supply, delivery, and erection in the electricity generating station to be established by the Council at Greenwich of four 5,000-h.p. vertical-horizontal steam-engines, each suitable for driving a three-phase generator. Particulars, etc., may be obtained at the County Hall, Spring-gardens, S.W. Tenders by 10 a.m. on Oct. 6.

Birkenhead.—The Corporation invite tenders for cleaning and painting the poles and bracket arms in connection with the Corporation electric tramways. Specification, etc., may be obtained at the office of Mr. William Bates, A.M.I.C.E., borough electrical engineer, Craven-street Works, Birkenhead. Tenders to Mr. Alfred Gill, town clerk, Town Hall, Birkenhead, by 5 p.m. on 22nd inst.

Bradford.—The Corporation invite tenders for the construction of about 13 miles of light railways and tramways in connection with the Angram storage reservoir works. Plans may be seen and specifications, etc., obtained at the office of Mr. James Watson, M.I.C.E., waterworks engineer, Town Hall, Bradford. Tenders to Mr. Frederick Stevens, town clerk, Town Hall, Bradford, by 10 a.m. on Oct. 1.

Oldham.—The Electricity Committee invite tenders for arc and incandescent lighting and power circuits in Greenhill station, comprised in specification No. 9. Copies of the specification, etc., can be obtained from the Resident Engineer. Specifications can be seen at the offices of Messrs. Kennedy and Jenkin, 17, Victoria-street, Westminster, S.W. Tenders to be sent to the resident engineer, Mr. S. Wilmott Newington, by Oct. 6.

Bermondsey.—The Borough Council invite tenders for (Contract No. 12) the construction, supply, and erection of two dust-destructor cells, with furnaces, flues, etc., and storage bins, one water-tube boiler and brickwork settings, one water storage tank, with supports for same, and extensions to the steam, feed, and exhaust piping system; (13) the construction, supply, and erection of two 300-kw. steam generators, two 20-kw. feeder boosters, one 15-kw. motor-balancer, and sundry switchgear and connecting cables. Specifications can be obtained from Mr. Fredk. Ryall, town clerk, and may also be inspected (but not obtained) at the offices of the engineers, Messrs. Kincaid, Waller, Manville, and Dawson, 29, Great George-street, Westminster. Tenders by Sept. 21. See advertisement.

London, E.C.—Tenders will be received until noon on Sept. 28 (a for the supply of Swedish, Norwegian, or Finland red fir telegraph poles, to be delivered in London, at Northumberland Dock (River Tyne), West Hartlepool, Hull, or Grimsby, at Leven, Fifeshire, and at Swansea, Cardiff, or Newport; and (b) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot, as may be directed. The poles to be felled during the winter of 1903-4, and to be delivered during the following summer at the port at which the creosoting is to be performed. Butt sections, 2in. thick, stamped with the shipper's mark, from not less than three poles, to show the quality of timber offered, must precede or accompany the tender of any person who has not already supplied the Postmaster-General with poles. Forms of tender may be obtained from Mr. S. C. Hoolley, controller of stores, Stores Department, 17-19, Bedford-street, London, W.C.

Digitized by Google

RESULTS OF TENDERS.

Pietermaritzburg.—The tender of Callender's Cable Company for £3,141. 10s. 5d. has been accepted.

Grimsby.—The Corporation have accepted the tender of Messrs. Hewins and Goodband, for building a fan-house, etc., at the electricity works, Doughty-road, Grimsby, at £589.

Huddersfield.—The Town Council have accepted the tender of the Manns Patent Steam Cart and Wagon Company, Limited, for the supply, at the price of £540, of a steam motor wagon.

Newcastle.—The Corporation have accepted the tender of the Lorain Steel Company at £1,894 for crossings, etc., in connection with the tramway extension from Westgate-road to Scotswood-road.

Aston Manor.—The Town Council have accepted the tender of Mr. George Trentham, 38, John Bright-street, Birmingham (Contract No. 1), at £46,739. 13s. for Scheme No. 1, and £47,920 for Scheme No. 2 of their tramways, for which Mr. Robert Green, A.M.I C.E., is the engineer.

Johannesburg.—With regard to the result of tenders noted in our last issue we cull from *South African Exports* the following details: "The recommendations agreed to were as follows: (a) That the tender of the Brush Electrical Engineering Company to supply steel grooved rails and fishplates in accordance with Sections A and B of tramway specification No. 1, at the price of £63,686. 0s. 6d., f.o.r. Johannesburg, be accepted. (b) That the tender of the Brush Electrical Engineering Company to supply steel Vignoles rails and fishplates, in accordance with Sections C and D of the tramway specification No. 1, at the price of £10,863. 4s. 6d. f.o r. Johannesburg, be accepted. (c) That the tender of the Hadfield Steel-foundry Company, Ltd., Sheffield, to supply points and crossings (with manganese steel tongues and crossings) and lay-out work, in accordance with Section E of tramway specification No. 1, at the price of £5,355. 8s. 7d. f.o.b. British port, be accepted, and that an additional sum of £885. 12s. 6d. be sanctioned for the cost of the delivery of the material included in this tender. (d) That the tender of the Brush Electrical Engineering Company to supply tie-bars, sole-joists, etc., in accordance with Section F of tramway specification No. 1, at the price of £5,708. 19s. 8d. f o r. Johannesburg, be accepted. (e) That the consulting engineers be authorised to order such extras as may be required from the successful tenderers up to an amount not exceeding £8,000. At the outset of the debate an amendment was moved that the main tender for grooved rails and plates should be given to British manufacturers. The Council was going to British financiers, it was pointed out, for the loan, and it was questionable whether they would be encouraged to lend when they knew that the money was to be spent in foreign countries. Reference was also made to the position in the East, and in case of war, it was asked, would British cruisers protect Flemish tramway rails? On the opposite side the facts of the case were pointed out, emphasis being laid on the fact that the shipping ring had offered a special rate of 18s. 6d. to Durban and 20s. to Delagoa, whereas the rate for foreign rails worked out at 10s. 6d. per ton. The amendment was defeated by the casting vote of the chairman."

BUSINESS NOTES.

TRACTION.

King's Norton.—The Urban District Council have accepted a tender of £16,892 for the construction of tramways.

Brighton.—The Corporation are experimenting with a motor fire-engine which is easily capable of a speed of 20 miles an hour.

Dublin.—A public meeting of the residents of Finglas has approved the scheme of the proposed electric tramway between Dublin and Slane.

Ilkeston.—The receipts for the first three months of the working of the tramways have amounted to £2,802; the working expenses were £1,846.

Halifax.—The Corporation have yielded to the temptation of the chance of making £1,000 a year by means of advertisements in the tramcars.

Bradford.—By one vote the Town Council have decided not to have advertisements on the tramway cars. The loss will be equal to a 1d. rate.

Chesterfield.—The Town Council have adopted a scheme for electrifying and extending the present tramway system at an estimated outlay of some £87,000.

Crewe.—The Mayor has been asked to call a town's meeting for the purpose of discussing the various light railway proposals that are or may be before the Town Council.

Warwick.—The British Electric Traction Company have submitted plans of the proposed routes for electric tramways. The Council will consider the proposals at an early meeting.

Burton.—Following on the *plébiscit* of the town, which resulted in favour of the Sunday running of the electric cars, the committee have decided on a service on Sundays from 2 to 9.30 p.m.

Hayes.—The Parish Council have been informed by the Board of Trade that they have granted the tramways company an extension to April 9 in which to complete their line to Uxbridge.

Driffield.—The Urban Council have decided to approach the North-Eastern Railway Company with a view to securing a service of motor 'buses between Driffield and the villages between that town and Beeford inclusive.

Wrexham.—The extension of the Wrexham tramway line from Johnstown to the bottom of Hill-street, Rhos, has just been completed, and it will be opened as soon as the Board of Trade authorities have inspected the line.

Dewsbury.—Formal application is to be made to the Board of Trade for power to construct tramways along Wakefield-road, so as to communicate with Soothill Nether, *via* Earlsheaton, and Ossett, and along Leeds-road and Crackenedge-lane, to serve Soothill Upper.

Wolverhampton.—On Friday the Tramways Committee decided to purchase the 11 miles of track from the Lorain Steel Company for £22,000, on condition that the company supply 5,000 new contact boxes. This decision has yet to be confirmed by the Council.

Northampton.—The Corporation have received the sanction of the Board of Trade to their borrowing the sum of £85,000 for tramway purposes as follows: £55,400, permanent way, buildings, and contingencies; £19,600, electric equipment and machinery; £10,000, cars.

Paisley.—The Glasgow tramway connection with this place will be opened in about a month's time. Probably the first part of the electric tramway system in Paisley will be completed by March next, and the whole system is expected to be in working order in June next year.

Flint.—It has been decided by the County Council to inform Messrs. Rowcliffe and Co., Manchester, solicitors to the promoters of a scheme for laying down a system of tramways over a circular route in the county, that the project would be favourably considered when submitted in the form of a Bill.

Devonport.—The new tramway extensions on the system leased by the Devonport and District Tramways Company, which were completed recently, have now been opened for traffic. Colonel von Donop, Board of Trade inspector, visited the new routes, and his sanction to their opening was obtained a fortnight ago.

Wigan.—At a meeting of the Corporation Tramways Committee on Tuesday the action of the manager in discharging a number of men was confirmed. A letter from the secretary of the tramway men's union asking for an interview with reference to the discharged men and other matters was considered. The committee unanimously refused to see him on any matter affecting the tramway management.

Leeds.—The inequalities of the existing fare system on the city tramways were discussed by the Traffic Sub-Committee at their last meeting. The sub-committtee agreed to recommend to the full committee that the first 1d. stage outward from the city should be universally fixed at two miles, and Mr. J. B. Hamilton (the general manager) was instructed to report on the practicability of the scheme.

Rotherham.—Two Corporation tramcars came into collision on a single line in Westgate, about 30 yards from the loop at the bottom of that thoroughfare. A dense fog prevailed at the time. None of the passengers were injured, but No. 17 car was badly damaged, the platform being broken. No. 16 car escaped with less damage to the platform and a broken plate-glass window. Both cars were put out of use.

Guildford.—A proposal by the West Surrey Light Railways Company to lay down a system of electric tramways in Guildford and the district is at present under consideration. The scheme includes the connection of Stoughton, Merrow, Stoke, and Shalford with the town. This would be a great boon to the inhabitants, as the villages at present possess very inadequate means of communication with Guildford.

Electric Signalling.—The North-Eastern Railway Company are reported to be experimenting at York with a system of electric signalling similar to that in operation on the London and North-Western Railway at Crewe. The work is now almost complete, and the system will be given a trial on Sunday, the 20th inst. It is being installed by the Railway Signalling Company, Limited, of Fazakerley, Liverpool.

London County Council.—The traffic returns of the London County Council tramways for the week ending Sept. 5 show that the receipts amounted to £10,731, against £8,144 in the corresponding week of 1902. The number of passengers carried was 2,716,294. The aggregate receipts this year to date are over £228,000, against £194,000 at the same period of last year, but the total mileage open is now 39¼ miles against 26⅝.

Bolton.—A sub-committee has been appointed to confer with Lord Bradford's agent with respect to land for additional car-sheds on Manchester-road. The engineer has been instructed to report as to the extension of the Chorley Old-road tramlines to Doffcocker Mill and Bobs Smithy, and as to the population of the district. A sub-committee has also been instructed to consider the question of the general management of the tramways and report.

Scarborough.—The tramways company have replied to the Corporation's request to name a price at which they would be prepared to sell the undertaking, the company stating that they are not desirous of selling at the present time, but that they would be prepared to consider any offer if the Corporation liked to mention the sum which they would be prepared to pay. The Corporation, however, have decided not to proceed further at the present time.

Dundee.—The promoter of the suburban tramway has entered upon the preliminaries necessary for laying his proposals before Parliament. The agreement between the promoter and the municipality has been signed by the parties concerned. The preparation of the plans will now be pushed forward with all dispatch so that they may be ready for lodging with the application for the provisional order, which must be submitted before the end of November.

Cowpen.—At the last meeting of the Council a letter was received from the Tyneside Tramways Company in reply to a communication of enquiry from the public authority pointing out that extensions of

Digitized by Google

existing lines in the immediate neighbourhood were being proceeded with, and that probably the directors were wishful to complete these before taking in hand the Blyth scheme. It was further stated that the Blyth tramways scheme would be undertaken without any delay which could be avoided.

Ayr.—At the Town Council meeting on Monday the convener of the Tramways Committee read the report by the manager, Mr. Frederick Coutts, on the year's working. This showed that the distance run by the cars had been 336,049 miles; number of units of electric current used, 335,893; cost per car mile, 1·39d.; passengers carried, 3,201,586; working expenses per car mile, 5·04d.; total expenditure per car mile, 9·01d.; total drawings per car mile, 10·11d.; average fare per passenger, 1·03d. The total working expenses had been £12,621. 17s. 7d., leaving a profit of £1,538. 16s. 1d.

Taff Vale Railway.—The passenger train service between Llantrisant and Aberthaw on the Taff Vale and Cowbridge and Aberthaw Railways has been discontinued, and a motorcar capable of accommodating 50 passengers is now run between the places named. The directors resolved on the alteration in consequence of the small number of passengers who travel from Llantrisant down. Occasionally a train of eight or nine coaches is seen travelling quite empty. The motorcar stops at all stations, and also at all level crossings, where necessary, to put down or pick up passengers. The fare is 1d. per mile or fraction.

Musselburgh.—The Town Council at their monthly meeting received intimation from the promoters that the Royal assent had been given to the local electric tramway order on Aug. 11. The Council was reminded by the clerk that the promoters had undertaken to begin work on the tramways within five weeks of the Royal assent being given to the order, and also that the electric lighting installation would proceed concurrently. The specifications were now out of the hands of the Edinburgh electrical engineer advisers of the company, and were in London, where prices were being got in. Everything was being done to get a start made.

Chester.—The Tramways Committee have resolved that the city surveyor prepare a plan and submit it to the committee, and report whether any and what road widening will be necessary in connection with the proposed tramway extension to Boughton, and that the electrical engineer and tramways manager confer and report as to the best mode of working a service to Boughton. An alternative suggestion was made to run trolley 'buses on the same route as the horse 'buses are now run—viz., Boughton to Bache—and the electrical engineer was requested to obtain information with regard to the cost and working of trolley 'buses and report.

Additional Traffic Returns.—Anglo-Argentine, £1,928 increase; Barcelona Ensanche y Gracia, £214 increase; Barcelona, £4 decrease; Brisbane, £4 increase (month of August, £11,736, increase £294); British Columbia Electric (month of March), gross earnings £10,352, net income £2,658; Buenos Ayres and Belgrano Electric, £252 increase (month of August, £13,431, increase £533); Calcutta, £383 increase; Cape Town (month of August), receipts £15,349, expenditure £8,696; Isle of Thanet Electric, £307 decrease; Mexico Electric (month of August), receipts £48,600; expenses, £27,900; Perth Electric, £127 increase; Port Elizabeth (month of August), receipts £3,875, expenditure £2,305.

South London Tramways.—At Wednesday's meeting of the Camberwell Borough Council a letter from the Board of Trade was submitted stating that, after careful consideration of the points put forward by the Council, the Board had decided to approve of the plans for the construction, by the London County Council, on the underground conduit system of electrical traction, of the following tramways: (*a*) from Camberwell-green *via* Denmark-hill, Champion-park, Grove-lane, Dog Kennel-hill, Grove-vale, and Lordship-lane to near the junction of that thoroughfare with Crystal Palace-road; (*b*) at Denmark-hill, connecting the above line with the existing tramway in Coldharbour-lane.

Batley.—Four of the eight electric cars originally ordered by the Corporation have been delivered at the Frost Hill depôt, Liversedge. Every endeavour is being made by Mr. Jones, the electrical engineer to the Batley Corporation, to be ready so far as the supply of energy is required. The service, however, cannot be inaugurated before the middle of next week at the soonest. The cars are being equipped as expeditiously as possible, with a view to early trial trips on the Batley lines. Much disappointment has been felt among the public at the delay in the delivery of the cars, it being fully expected that Batley Feast would at least see a commencement of the running to Healey and Staincliffe.

Tramway Material for Railways.—The Aberdeen Harbour Board have decided to reconstruct the whole of the numerous railway junctions, etc., running round their docks, and, in doing so, are departing from the usual railway practice of having built-up switches and crossings, but are adopting tramway practice of constructing them in solid castings, adopting Hadfield's manganese steel. The lines take the very heavy traffic from the docks on to the N.B. Railway, who use the new 30-ton long wagons, and it speaks well for the reliability of this material that it has been found suitable for this purpose. The experiment will, no doubt, be watched with interest by other permanent-way engineers.

Lowestoft.—So far the new bogie cars recently put in service by the Tramways Committee have not worked very successfully. There was a discussion on the subject at the last meeting of the Town Council. The manager reported that the bogie cars would not run properly, and the town clerk was directed to inform the Westinghouse Company that the committee have fully considered the matter, and are advised that the cars are incomplete, and are not delivered in accordance with their contract; that damages are accruing under the terms of their contract for non-delivery, and to inform them that the Corporation will enforce the terms of the contract, and request their immediate attention to the matter.

Tramway Standards in the Streets.—At a meeting of the Manchester Trades Council held yesterday the General Railway Workers' Union presented the following resolution: "That having taken into consideration the regulations recently obtained by the Manchester Corporation, which give them strict authority over the centre of certain routes, we urge upon the Tramways Committee the necessity of immediately removing all electric standards to a safe distance inside the kerbstone. The carrying out of this suggestion will assist in securing the safety of the public and will also tend to prevent collisions between tramcars, drays, carts, and other vehicles, which are now of frequent occurrence."

Another "Tube" Breakdown.—Another breakdown on the Central London Railway occurred on Thursday night last week almost in the same place where a mishap took place on the previous Tuesday. The train was being shunted at the cross-over road at the Bank Station when one of the coaches fouled the points, striking the centre or current rail, causing a slight explosion. The current was cut off between the Bank and the British Museum Stations, and the emergency current was turned on to light up the tunnel and intermediate stations. Trains containing nearly 200 passengers stopped near the Bank Station, but they alighted, and without disorder walked along the track to the station and were conveyed to the surface. There was no panic.

Edinburgh and Leith.—A conference has taken place between representatives of Edinburgh Corporation and Leith Town Council with the view of discussing the question of the restoration of a through tramway service between the two towns. The alternatives of carrying the cable which now goes to Pilrig down to the foot of Leith-walk, and of carrying up the electric system which Leith proposes to adopt from Pilrig to St. Andrew-square, were discussed, and ultimately it was agreed that the Leith Committee should have a conference with the Edinburgh tramway lessees to see what they would agree to by way of having the two systems worked by them as one concern. The conference was purely informal, as the representatives had no powers to decide in any direction.

Torquay.—The Dolter Electric Traction Company are promoting a Bill to introduce their system of surface contact in this place. They are offering the Corporation special inducements, as, contrary to the usual practice, they have not mapped out their own routes, but have agreed to adopt those selected by the consulting engineer to the Corporation. They are also offering a very fair price for the electric current, the supply of which would greatly assist the town's electrical undertaking. The company propose to start with a small scheme, embracing the union of the two railway stations and a swift means of communication between St. Marychurch and Torquay. The Dolter Company intend shortly to give a practical exhibition of the working of their system on a temporary piece of line at Castle Circus.

Greenock.—The Corporation have approved the plan of a new car proposed to be used in Greenock, subject to the tramway company reducing the height of the step from 15in. to 11in. It was agreed to communicate with the company and request that the cars and points should be put into proper order, so as to lessen the excessive noise made by the cars. It was stated by the engineer that during the time of the America Cup races a supply of energy had been taken from the trolley wires for lighting a specially illuminated car, and a connection had also been made from the trolley wires in Gourock to illuminate the premises of the yacht club. It was agreed to notify the company that in future the Corporation's consent would have to be obtained and special terms arranged for any supply used for other than tramway purposes.

Competition.—The introduction of electric cars into Manchester has had the effect of reducing the number of licensed 'busmen from 146 to 47, and of cabmen from 762 to 576. Yet there are only 448 electric cars as against 520 of the old horse-cars. The lumbering omnibus has almost disappeared, except for pleasure party traffic. The most astonishing fact recorded in the Board of Trade's annual railway return just issued is that, while the number of third-class railway passengers only increased in 1902, as compared with 1901, by 11,706,000, tramway passengers increased by 196,226,000. Last year the former totalled 1,080,625,000, while the tramway travellers aggregated 1,394,453,000. The total capital of the railways of the kingdom now stands at £1,216,861,000, and their net earnings last year were £41,629,000.

Aston.—The District Council had a special meeting on Monday to consider the report of the Tramways Committee with regard to the electrification of the tramways in the district. The committee had considered two alternative schemes, and recommended that a double line of tramway be constructed along Aston-road from the city boundary, Aston-road North, and Lichfield-road, with a single line under the railway bridge at Aston Station, and a double line of tramway in Victoria-road from the Vine Inn to the Six Ways, the work to be executed by Mr. George Trentham, of Birmingham. The recommendation was agreed to negotiate for loans for the following purposes: purchase of tramways, £70,000; for work agreed upon that evening, £32,500; for overhead equipment, £10,000; and cost of the electric generating station, £62,000.

Newcastle.—At the last meeting of the Tramways Committee it was agreed to instruct Mr. Edge, the city engineer, to go on at once with the tramway extension from the corner of Clayton-street and Westgate-road to join the Scotswood-road section at the cattle market. The contract was let for the providing of crossings, etc., for this work to the Lorain Steel Company for £1,894 on the distinct understanding that they should be ready in six weeks. The question as to the extension of tramways *via* Dean-street to the Quayside was referred to the city engineer to report upon. It was agreed to convene a special meeting for Oct. 9 to take into consideration suggested negotiations with the Tyneside Tramway Company for the proposed interchange of traffic. It was decided to extend the present line of rails from the top of Shields-road to Chillingham-road.

Digitized by Google

Berlin.—The Berlin correspondent of the *Standard* says that the Berlin Tramway Company has conceded a rise in wages to all its employés, which involves an additional outlay of 275,000 marks per annum. The intervals fixed for the automatic advance to higher scales of wages have been considerably shortened. Nevertheless, the pay can hardly be described as ample. The drivers and conductors are to receive £4. 15s. a month during the first year of their appointment, and the maximum pay of £6. 5s. in the sixteenth year of their service. It is true that the conductors earn a good deal of money besides their salary through the halfpenny "tips" generally given them, not only by the well-to-do, but also by common people. The drivers get no "tips," but every driver advances to the position of conductor after a certain term of service.

Paris Tube.—A Paris correspondent states that an accident to the motor of one of the trains on the Paris Tube Railway on Tuesday morning caused it to come to a standstill in the Châtelet Station. The passengers had to leave the train, but the service was resumed after a delay of 20 minutes. The opening of the Metropolitan Railway seriously affected the traffic receipts of the Paris Omnibus Company, and some of its services were even abandoned. The nervousness which the recent series of accidents has created among the public has, however, caused the company's receipts to increase considerably, and there are rumours that some of the old lines may be restored, and notably that of the Hôtel de Ville to the Porte Maillot, which was a favourite ride for tourists, since it took them along the Rue de Rivoli by the Tuileries, and then up the Champs Elysées and round the Arc de Triomphe before reaching the fortifications.

Handsworth.—The District Council are anxious to get their tramways questions settled without any delay. They are particularly anxious that the half mile now served by the British Electric Traction Company's steam trams shall be electrically equipped, so that there shall be a through service from the Black Country to the cable trams at Handsworth. The Council have decided to purchase the section from the British Electric Traction Company, and have offered £5,000 for the old lines and tram-sheds, but the company want another £2,000. If the Council's offer is not accepted, the matter will probably be submitted to arbitration, and another tantalising delay caused. Meanwhile plans are being prepared for the electrical equipment of the lines, and as soon as negotiations have been completed the work, which will entail an outlay of £15,000, will be commenced.

Automobile Club Reliability Trials.—The fifth annual reliability trials of motorcars organised by the Automobile Club were begun at the Crystal Palace on Wednesday, and will continue until the 26th inst. There is a record entry of no less than 130 cars, of which considerably over one-half are of British manufacture. A series of brake and dust-raising tests were conducted in the palace grounds on the opening day, and these continued yesterday. For the latter test quantities of flour have been spread out upon the race track, and, as the cars are driven over it, photographs of the cloud which is raised are made by the judges. To-morrow (Saturday) the long-distance runs of from 90 to 150 miles a day will commence, the first run being made to Margate and back. On the following seven days the motors will visit, in succession, Eastbourne, Worthing, Folkestone, Southsea, Bexhill, Winchester, and Brighton. In this way a total distance of over 1,000 miles will be covered by each car.

Tramway Inspection.—There is much that is valuable to be gained by an interchange of courtesies between municipal authorities who have the responsibility for the success of the local tramway undertaking in their own hands. The growing importance attached by outside municipalities to the electric tramway system of Liverpool is shown by the frequent applications made to the Corporation for permission to study the conditions under which it is conducted. On Sunday a body of 28 tramway officials from Leeds visited the city for the purpose of obtaining information as to how Liverpool manages its tramway affairs. They were courteously received by the general manager, Mr. C. B. Bellamy, who, with other officials, took them over various routes and through different generating stations, and fully explained to them the working and equipment of what is now acknowledged to be one of the most up-to-date and successful electric tramway enterprises in the kingdom.

Bury, Rochdale, and Oldham Tramway.—In the report of the directors of the Bury, Rochdale, and Oldham Tramway Company, Limited, for the half-year ended Jan. 31 last it is stated that notices to purchase under the Tramways Act, 1870, have been given by several of the local authorities for certain sections within their respective districts, and Sir Frederick Bramwell, Bart., has been appointed referee by the Board of Trade. An interim working agreement was desired by the local authorities, and a number of clauses, called "Heads of Agreement," were after discussion agreed upon and accepted in writing by both sides. The authorities have since expressed a determination not to be bound by the heads of agreement but the Board are advised that a binding contract had been entered into, and should be carried out, unless an arrangement is mutually come to for modifying or cancelling it. They have taken, and will continue to take, such steps as they deem best to protect the Company's interests, both as regards the working agreement and the arbitration.

Reading.—The following is from the *Berkshire Chronicle*, and we print it for what it is worth: "In consequence of so many axles breaking, it has been decided to use only the outside rail in coming down and going up London-street, so as to avoid the awkward curve of the inner rail at the top of the street. Scarcely a day has passed without at least one car breaking down through the axles giving way, and on some days two have done so. About 10 cars have been in the shed *hors de combat* every day of the week, and the strain is so great that both axles have been removed from some of the broken-down cars and the good one placed on another car. These unfortunate series of accidents emphasise the arguments of those who have urged that more cars are needed. But it must not be forgotten that there is little room for more cars in the shed unless it is enlarged. Another suggestion of the 'experts' is that bogie cars are more suitable for the tramways, as there are so many sharp curves, and that if we had them the breakdowns would not happen. Whether that is so or not is for the real experts to decide."

Ashton.—A motorman, formerly in the employ of the Corporation, was fined 7s. 6d. by the local bench last week under curious circumstances. The charge against him was one of "exposing valuable property to serious injury." It appeared that on Aug. 21 the defendant on taking his car to the depôt at Mossley-road left the controlling handles on, and also left the mechanism controlling the current in such a way that anyone passing and touching the handles would have resulted in the car starting, with no doubt serious injury to property or life. On receiving the report, Mr. Coveney, the tramways manager, directed Inspector Davies to see the defendant and tell him that for his gross neglect of duty he would be reduced for a time to the position of conductor. Davies boarded the car near the Albion Schools, and rode down towards the bowling green. When spoken to the defendant said he had a good mind to chuck up the job. Davies told him it was nonsense, and some little discussion took place, the end of which was that the defendant picked up his basket and walked off, saying Davies could take the car. By this time a number of passengers had got seated in the car. Fortunately Davies was able to take the car up to the depôt, and another motorman was obtained to take the service.

Erith.—The Tramways Committee reported to the last meeting of the District Council that the Tramways and Improvement Bill had become law. The committee had discussed with Mr. Hawtayne the question of proceeding with the construction of the proposed tramways, and had considered the resolution forwarded to the Council by the Erith and District Tradesmen's Association and the memorial signed by a number of ratepayers in support of such resolution. The committee recommended that the whole question of tramways be considered by the General Purposes Committee of the Council. The committee, however, expressed their opinion that if it was the intention of the Council to proceed with the construction of any part of the tramways forthwith, the following routes should be the first constructed—viz.: part of tramway No. 1, commencing in Bexley-road at the boundary of the parish of Crayford at Northumberland Heath by a junction with the Bexley tramway, along Bexley-road to Bexley-road Bridge; tramway No. 2, along Pier-road; part of tramway No. 3 from the corner of Pier-road in a southerly direction along High-street, Crayford-road and South-road to the boundary of the parish of Crayford; and tramway No. 8, along the new road through the Walnut Tree House estate. The report was adopted.

Salford.—The Tramways Committee have prepared their report on the working of the Corporation tramways for the year ended March 31. It shows that the receipts were altogether £141,486. There were covered 3,380,590 car miles, and the cars carried 28,150,675 passengers. The monthly receipts rose steadily from £9,390 in April, 1902, to £13,127 in March, 1903. Whitweek in 1902 gave the highest receipts for any one week—namely, £3,632. In the 11 months before the period mentioned the number of passengers carried was 10,352,675 (or rather more than a third of the year's figures), the receipts £88,639, and the miles run 2,107,868. The earnings per car mile show little alteration, being 10·25d. in 1902-3, against 10·09d. in 1900-1. The total expenditure for the year was £104,969, and this left a gross profit of £39,856. Out of this £26,865 has been applied to interest and sinking fund charges; £2,990 has been set off for reserve and renewals, leaving £10,000 to be contributed in aid of the rates. No special provision has been made for depreciation charges apart from the reserve and renewals fund. On March 31 the Corporation owned 100 cars. The total electrical energy used during the year was 3,370,434 units. On the same date there were 35 miles of track open in and 8½ miles outside the borough. The average fare was 1·2d.

Underground Electrification.—Last week we reproduced from the *Financial Times* an article contributed by a "Railway Expert" commenting upon the working of the Inner Circle by the two owning companies, and contending that an interchange of rolling-stock between the two companies would be quite impracticable because different systems of multiple-unit control have been adopted. That paper has since been informed that this is not the case, and that the Circle traffic will in no wise be affected by this condition. The collector-rail equipment and all the parts of trains and tunnels affecting an interchange of stock will be identical, and not only the electrical trains of both companies, but also their steam trains and those of outside companies will run over the tracks during the period of electrification. As an example of this, the District steam trains are equipped with the Westinghouse automatic air brake and at the present time the Metropolitan steam trains have the vacuum brake, but this does not prevent interchange of stock. In the future the air brake will be used for all electric trains. A further invention of Mr. George Westinghouse, intended for use on railways generally, but more especially for electric railways, consists of an automatic coupling, which in one piece of apparatus takes the place of all the numerous connections required between electric cars—viz., the draw-bar, the buffers, the brake hose, and the several electrical circuits. The simple bringing together of the carriages automatically completes all connections necessary for the running of the train. Thus the time occupied in making up and splitting trains will be greatly reduced, and the risk to the shunter in being compelled to crawl between and under carriages in close vicinity to electric circuits at pressure high enough to give a very severe shock is entirely abolished.

South African Railways.—Mr. Hoy, chief traffic manager on the Central South African Railways, writes as follows on the subject of steam *v.* electricity: "The success with which heavy locomotive engines are now being employed in these colonies, as well as in England, points to the maximum having been nearly, if not actually, reached. A 120-ton locomotive upon an 80lb. rail, on a 3ft. 6in.

Digitized by Google

gauge, is what would generally be considered a favourable result. If the locomotive limit has been attained, there are evidences of developments in substituting a newer motive power upon lines where the nature of the traffic to be conveyed renders it possible to utilise electrical or other systems of energy. The employment of the heavy locomotive has its unquestioned economic merits, but it is an important consideration whether freight vehicles may not with advantage be equipped with their own motive power, either for individual or collective haulage The grade will always largely influence the value of the locomotive, but upon sections admirably adapted for the use of electricity, the adhesive power may with advantage be abandoned for the energy attached to the vehicle itself, and thus overcome the resistance common to the present system of haulage. Whether the power to be employed be electricity or a combination of other forces, there can no longer be any doubts that upon short and busy lines steam can be superseded. If any section of railway in South Africa lends itself for advancement in this direction, the Springs-Randfontein length offer an admirable opportunity for the expansion of such scientific energy. The working of so many mines sidings might assure the success of a change in working. There is a further guarantee of sufficient traffic within the section. I assume that electricity will supersede steam for passenger work along what is known as the Rand Tram Section within a measurable space of time. There are excellent opportunities for installing electricity, and of taking early steps not only to cultivate the suburban traffic, but to retain it."

Snowdon.—A local paper gives some interesting information about the scheme which the North Wales Power and Traction Company are promoting for an electric light railway or tramway system in the Snowdon district. The scene of the initial operations is Llyn Llydaw, one of the lakes on the slopes of Snowdon, where the River Glaslyn has its source. Here it is intended that the first generating station shall be situated. Important proposals have already been made by the company to a number of private firms and public authorities in the county, with a view to an extensive supply of electric power and light at low rates throughout the district. Among the more important schemes under consideration are the construction of a light railway from Portmadoc, through Beddgelert to Rhyddu, to join the present narrow-gauge railway, which will then be extended from Dinas to Carnarvon, the whole line to be worked by electricity. This will not only bring Portmadoc and the county town into direct connection but will open up an independent line of communication for North Carnarvonshire with the Cambrian Railway system. It is also proposed to electrify the Snowdon Mountain tramroad to the summit, and to supply electric power to the quarries in the Nanttle Vale, the Gwyrfai district, and Llanberis. A further intention is to make the Carnarvon Corporation an offer which, it is alleged, will be far more advantageous to the borough than those recently negotiated with another company, the new offer, it is said, being calculated to save the town from 40 to 50 per cent. of the now contemplated outlay, while enabling the residents to get a supply of electric light at a much lower rate than was proposed under the other scheme. All the towns of the Menai Straits, including Beaumaris, Bangor, Menai Bridge, Port Dinorwic, and Carnarvon, are embraced within the scope of the contemplated operations, it being argued that if these towns combined in one common scheme for generating electricity by water power, an enormous saving would be effected in each. The supply produced at Llyn Llydaw will, it is alleged, be not only ample for these purposes, but will leave a residue available for working tramways in the future from Carnarvon to Clynnog, Nevin, and Ebenezer, and from Talyfoel, on the Anglesey side of the Straits, to the surrounding villages in that county.

LIGHTING AND GENERAL.

Bo'ness.—The Town Council have acquired a site for a generating station.

West Bromwich.—The Town Council propose to expend £12,000 in electric lighting works.

Grimsby.—Sanction has been received to the borrowing of £7,000 for the electric lighting extension.

Swansea.—About £200 is to be spent in equipping the fever hospital with the electric light.

Swansea.—The Mayor is to be invited to formally declare the telephones open at a date to be fixed shortly.

Walton-le-Dale.—The Urban District Council have decided to apply for an electric lighting provisional order.

Cromer.—The Urban District Council have adopted the Union Electric Company's "Flame" lamp for arc lighting purposes.

Ince.—The Board of Trade will defer consideration of the question of revoking the Council's electric lighting order for 12 months from July 26, 1903.

Dorking.—Messrs. Edmundson's list of the roads in which they propose to lay mains is before the Electric Lighting Committee of the Urban District Council.

Southend.—An enquiry has been held into an application of the Town Council for sanction to borrow a further sum of £20,000 for electric lighting purposes.

Berwick.—The draft of the contract with the Urban Electric Supply Company for the lighting of the streets will come before the next Council meeting for completion.

Direct West India Cable Co.—A further dividend of 3 per cent., making 6 per cent. for the year ended June 30 last, is recommended by the directors in their annual report.

Carlisle.—The engineer reported to the Electricity Committee on Sept. 1 that since the last meeting he had received seven applications for new lights equal to 240 8-c.p. lamps.

Chippenham.—The Town Council have resolved to apply to the General Post Office for a complete telephone service night and day. At present they are cut off to the world after 9 o'clock.

Cowes.—The electric light is to be installed at once in Holy Trinity Church. Instead of driving the organ by gas power, electricity is to be the motive power for supplying the wind.

Removal.—The Berliner Telephone Manufacturing Company, 117, Queen Victoria-street, E.C., has removed to larger and more commodious premises at 200, Upper Thames-street, E.C.

Barry.—The District Council have authorised a deputation to consult with the South Wales Electrical Distribution Company to consider the question of supplying electricity in the district.

Kingswinford.—For the last two seasons the Council have been expecting the Midland Electric Corporation to be ready to supply electricity for public lighting, and they are apparently getting impatient.

Rhyl.—The Council are raising a loan of £1,300 from the Public Works Loan Commissioners for street improvements and in connection with the refuse-destructor works, and £10,098 in connection with the electric light works.

Whitehaven.—The Council have received sanction to borrow £2,500 on account of electric lighting. The original electric lighting loan was for 30 years; the last was for 10 years, and this one being for 25 years, will ease the burthen.

Vienna.—A Laffan's wire states that an incandescent electric lamp trust has been formed by the most important manufacturers of Central Europe. The trust is made for a period of 10 years. A central depôt for the sale of lamps will be opened.

Dorchester.—As a result of an interview with Mr. J. Enright, electrical engineer, the Electric Lighting Committee are of the opinion that without impairing the efficiency of the installation the cost could be considerably reduced on the first estimates.

Wrotham.—At the last Council meeting it was proposed that a small committee be formed for the purpose of helping the Kent Electric Power Company to get a provisional order for the purpose of supplying the district with electric light. No action was taken.

Islington.—The work of excavating for the extension of the electric arc lighting in the Canonbury district has been commenced, the first blow being struck in Petherton-road (Grosvenor-road end) by Mr. Councillor Samuel Lambert, chairman of the Lighting Committee.

New Branch.—The British Westinghouse Electric and Manufacturing Company, Limited, have established a new district office at Central House, New-street, Birmingham, under the management of Mr. G. K. Chambers, formerly contract manager of the British Insulated Wire Company.

Walton.—The Urban District Council are in communication with the Weybridge Electric Supply Company in reference to the lighting of Walton. An Electric Lighting Committee has been appointed to go into the whole question of the policy to be adopted in regard to the provisional order recently obtained.

Cambridge.—Messrs. Handcock and Dykes, of 1, Victoria-street, Westminster, have been retained to advise on the subject of electric lighting at the University Library, where, owing to the value of its contents, very great care has to be taken for the prevention of fire. The Cambridge Electric Supply Company are, we understand, to carry out this contract.

Stock Exchange.—Application has been made to the committee to allow the following securities to be quoted in the official list: Metropolitan District Railway Company's £2,116,666 3 per cent. consolidated rent-charge stock, in lieu (partly) of the 4½ per cent. Ealing rent-charge stock and the 4½ per cent. Fulham rent-charge stock now quoted.

Llandudno.—The statement of the revenue account of the electric lighting undertaking for the year ended March 31 last shows that after making provision for the repayment of loans and interest there was a deficiency on the year's account of £368. This deficiency was, however, provided for out of the balance of £427 which stood to the credit of the undertaking at the commencement of the financial year.

Cardiff.—Mr. Arthur Ellis, electrical engineer and manager, in his last report states that there are 868 private consumers connected with the mains, equivalent to 87,416 8-c.p. lamps, showing an increase of 58 per cent. in the total connections as compared with the same time in the previous year. The estimated revenue in July was: for street lighting £400; private supply, £1,295. 11s. 4d.; and in August: street lighting, £420. 3s. 8d.; private supply, £1,384. 3s.

Coventry.—The Corporation Electric Light Committee have agreed to recommend that from Oct. 1 consumers be allowed the option of paying for current for lighting either according to the present system or at a flat rate of 4½d. per unit, provided that the option is exercised for a period of not less than 12 months. The committee also recommend that from the same date energy for motive purposes be supplied at the present rate of 1¾d. per unit up to a consumption of 2,500 units per quarter, and of 1d. per unit for all consumption beyond that figure.

Carnarvon.—The Council have entered into a provisional agreement with the National Electric Wiring Company for an electric installation at Carnarvon, the Corporation providing capital to the extent of £17,000, and the company undertaking to construct the works and to maintain them for a period of years, repaying the Corporation annual instalments of principal and interest on the loan, together with all profits over and above a specified amount. Since the Corporation made this provisional agreement the North Wales Power and Traction Company, Limited, had made an offer. The enquiry by the Local Government Board has been fixed for Tuesday next.

Digitized by Google

Devonport.—The Council have received sanction to loans of £9,650 and £19,272 for the purposes of the electrical undertaking, the former amount being in respect of works already carried out and the latter in respect of proposed new works. Agreements have been concluded for the supply of electricity to the Royal Naval Hospital, Royal Naval Barracks, and Sir John Jackson's works.

Lifts.—The Royal apartments used by H.M. the King last week at Doncaster racecourse have been furnished with an electric passenger lift by Messrs. Archibald Smith and Stevens. The machine is a duplicate of that erected for the King's personal use at Epsom by the same firm, and was during the King's visit under the care of Mr. Major on behalf of the makers and of the Doncaster Race Committee.

Huddersfield.—Negotiations are proceeding between the Golcar Urban District Council and the Electricity Committee of the Town Council for the extension of the electricity mains to that township. A deputation has decided to recommend the District Council to approve similar terms to those arranged between the Corporation and the Linthwaite Council subject to the mains being laid in the principal streets within two years from the commencement of the order.

Peat Coal.—As a consequence of a number of experiments with the treatment of peat by electricity, a demonstration of a new patent process is to be held shortly by Messrs. Johnson and Phillips, Charlton. We are informed that the extraction of moisture is carried out quickly, and can be continued all the year round at comparatively low cost. A demonstration of the process on a large scale has been arranged, and we defer further particulars until after that event.

Glasgow.—The Council have approved a report of Mr. Lewis, stating that 54 lamps would be required to light Victoria Bridge, Main-street and Cathcart-road up to Dixon-avenue with electricity, at an annual charge of £756, with an estimated cost of erection of £1,245, and a probable charge of £324 for electric fittings. The annual charge of the 128 gas lamps in that district was £252. 15s. 5d. The consideration of the matter is to be continued. The estimates, which were before the Corporation a few weeks ago, show a proposed additional expenditure of £3,000 for electric lighting.

Pemberton.—Cables for public lighting and private supply have been laid along a number of streets. The gas lamps have been taken down and pillars planted every 50 yards, as in the other parts of the district, and the whole will be lighted in the course of a few days. The number of applications for current has considerably increased over the previous month, also the services connected, and it has now become necessary to run both the small sets nightly. The Nernst lamps on trial have during the month given very good results, and it is proposed to substitute them for the ordinary lamps along Ormskirk-road.

Royce, Limited.—We are informed that this firm have now completed and started up new works at Trafford Park, Manchester, for the manufacture in quantities of dynamos and motors. The works cover a large area and include a fully-equipped ironfoundry. They are electrically driven throughout, have been expressly designed with a view to promoting rapid and economical production, and are equipped with a splendid selection of the latest automatic and other machine tools and labour-saving devices. The firm state that the resultant economy in the manufacture of their standard lines of machines has been such as to enable them to considerably reduce prices.

Hindley.—A letter from the South Lancashire Tramways Company as to lighting by electricity of the electric standards in Atherton-road and Liverpool-road came before the Council last week. The following queries will be discussed at an interview which is to take place shortly between the Council and the company's engineer: "Will the company fix on the 81 poles electric incandescent lamps, light them, and keep them in repair? Will they make the connection between the cable and the present poles to the lamps complete? Will they make good to the Council's satisfaction the road where they are compelled to cross? Will they light the lamps from one hour before sunset until half an hour before sunrise for the 365 days?"

Finchley.—The electrical engineer in his last report states that the boilers had been under steam, and the brickwork was thoroughly dried. The engines, dynamos, etc., were fixed and completed ready for the official trial, which would take place at an early date. Two sets had already been under steam. The battery had arrived on site, and was erected, and would shortly be ready for charging. Sufficient switchboard apparatus had been delivered to enable the supply to be commenced, but there had been delay owing to difficulty in procuring slate of satisfactory quality. In accordance with instructions, pipes were being laid to the proposed centre poles along the tramway track in the Great North-road. The electrical engineer has been authorised to purchase sleepers for the purpose of making-up a road for cartage over the soft ground round the works at a cost not exceeding £50.

Water Power.—A project has been worked out by Messrs. Charles Gochrich, C. de Lacroix, and E. Zuber to utilise the power of the Rhine between Niffer and Ottmarsheim, near Muelhausen, in Elsass. A canal is to be constructed from the former place to the latter, a distance of 8 km. to 9 km. The fall between the two points is now 8·40m., and is to be increased to 10m., by means of a movable weir constructed of six horizontal iron tubes, each of 3m. diameter and 26·70m. length, fixed into slots so as to be lifted in flood time. The minimum flow of water equals 300 cubic metres, and it is anticipated that 250 cubic metres could be used, and that they would produce 23,000 h.p. It is proposed to distribute this power over 16 sets, composed each of a turbine direct-coupled on its vertical axis to a three-phase dynamo. Half of the output will be conducted to Muelhausen, and the other half will be used for local power and lighting supply.

London Gazette.—The partnership heretofore subsisting between Frank Ashton Clayton and William Turner, carrying on business as electrolier and gasolier manufacturers, art metal workers, and general brassfinishers, at 2, Short-street and 25, City-road, Manchester, under the style or firm of Clayton and Turner, has been dissolved by mutual consent from June 13, 1903. The partnership heretofore subsisting between Henry Rossell and Hugh Rossell, carrying on business as electrical engineers and contractors, at 65, Alfreton-road, Nottingham, under the style or firm of H. Rossell and Sons, has been dissolved from Sept. 8, 1903, by mutual consent. A first meeting in the estate of Edwin Ward (trading as E. Ward and Co.), plumber and electrician, of 38, Osborne-road, lately residing and carrying on business at 108, Bevois-valley and 47, Lodge-road, Southampton, will be held at 3 p.m. on Sept. 21, 1903, at the Official Receiver's Office, 172, High-street, Southampton.

Steam-Turbine Plant for Lighting.—The increasing demand for light and power at the municipal lighting station at Anderson, Indiana, U.S.A., having rendered the present plant (comprising two belted generating units) entirely inadequate, two Westinghouse steam-turbine generating units, each of 400 kw. capacity, are being installed, together with a 20-kw. exciter direct-connected to a Westinghouse standard engine. By the employment of turbines extensions to the power-house itself have been rendered unnecessary, the capacity of the plant at the same time being largely increased. The additions consist of three 310-h.p. Stirling water-tube boilers, equipped with Roney mechanical stokers. They are being arranged to supply saturated steam to the turbines at 150lb. pressure, all condensation being returned to the boilers by a steam loop and Holly gravity system. Surface condensers will be used, and as the exhaust will be free from oil, the condensed water can be delivered direct to the boilers as return feed. Three-phase current will be furnished by the turbo-generators at 2,200 volts pressure, 120 periods.

King's Lynn.—The electrical engineer in his last report stated that since the previous meeting applications for a supply of electricity had been received from two additional consumers for 46 lamps of 8 c.p. or equivalent, making a total of 16,210 from private consumers. He further reported that all the four boilers had undergone their thorough annual inspection by the insurance company, and they report in each case that there are no defects affecting their safety. It was intimated that the wire in the regulation resistance had perished, and that it was being replaced with a wire of another kind. The electrical engineer also reported that the factory inspector required guards to be fixed over the flywheels of the two steam dynamos, and that he was having the work carried out. Messrs. Savage Bros. had written asking the price of one of the gas dynamos converted into a motor. He stated that the machine would give out when run as a motor about 45 h.p., and a new motor this size would cost about £200, and suggested that it should be offered for hire to Messrs. Savage at a rental of £16 per annum. The matter was left in the hands of a small committee. The engineer submitted the following statement: units generated, July, 1903, 18,149 (1902, 13.547); total units sold to private consumers (light and power), 8,638 (6,988); units sold at power rates, 4,919 (2.610); cost of fuel, stores, repaire, and wages at station, £100. 19s. 11d. (£107. 0s. 7d.); cost per unit generated, 1·33d. (1·89d.); wages of lamplighters and outside staff, £19. 15s. 3d. (£21. 6s. 4d.).

Swindon.—On the report of the electrical engineer as to the desirability of erecting a refuse destructor in connection with the electricity station, a sub-committee was appointed last week to report. It was resolved that the electrical engineer be authorised to fix a voltmeter in his private residence, at an estimated cost of 25s., for the purpose of indicating the supply pressure on the electric mains. The electrical engineer was also authorised, in the event of receiving applications for the supply of electricity to a greater distance than 20 yards from the electric mains, to extend the mains on the applicants giving an undertaking, to the satisfaction of the town clerk, to take a supply of electricity for the period of three years, which will give an annual return of 15 per cent. on the cost of the extensions. It was resolved that the scale of charges for recharging portable accumulators be as follows—namely: for recharging a four-volt accumulator, taking up to 20 ampere-hours, 9d.; for recharging a four-volt accumulator, taking between 20 and 40 ampere-hours, 1s.; for every 20 ampere-hours over and above 40 ampere-hours, 3d. The monthly report of the electrical engineer was read as follows: Number of consumers connected, May 30, 40; equivalent in 8-c.p. lamps connected, May 30, 2,727; number of consumers connected, Aug. 26, 75; equivalent in 8-c.p. lamps connected, Aug. 26, 4,280; horse-power of motors connected, Aug. 26, 33½; estimated units sent out (31 days), Aug. 26, 7,693; applications in hand, Aug. 26, 19 consumers, equal to 1,500 8-c.p. lamps.

Morley.—The last statement of accounts of the electricity undertaking shows some improvement upon that for the previous year, for although there has been an increase in the expenditure there has been more than a corresponding increase in the receipts. The expenditure showed the cost of generation of electricity to be £1,092. 11s. 10d., which included £476. 1s. 10d. for coal; £213. 11s 4d. for oil, waste, and engine-room stores; wages at the works, £314. 7s. 9d.; repairs and maintenance of buildings, £21. 17s.; machinery and plant, £66. 13s. 11d. The distribution of electricity cost £146. 19s. 4½d.; public lighting, £49. 1s. 5d.; rents, rates, and taxes, £99. 13s. 4d.; management expenses, £378. 16s. 4d., of which £292. 2s. 8d. was salaries of engineer and assistants; and special charges, £19. 12s. 10d.; the total expenditure amounting to £1,786. 15s. 1½d. The receipts included £1,364. 15s. 5d. by sale of current; £346 from public lighting; £53. 1s. 6d. from meter rentals; £22. 9s. 2d. miscellaneous receipts; and £154. 12s. for supplying steam for heating the baths; a total of £1,940. 18s. 1d., leaving a profit of £154. 1s. 11½d. In addition, however, there has been £1,021. 13s. 8d. paid for interest and £735. 3s. 8d. transferred to the sinking fund. The capital account shows an expenditure on the works and mains to date of £25,31

Digitized by Google

8s. 9d., and there is in the sinking fund £3,483. 14s. 2d. Mr. Ellis in his report states that the output of electricity during the four weeks ending July 12 was 5,645 units, against 3,831 units the corresponding period of last year. There had been 195 lamps connected during the month, the number of lamps connected to date being 10,497.

Felixstowe.—Mr. Wilson, the consulting electrical engineer, reported at the last Council meeting on the respective merits of gas or steam plant for the extension of the electrical station. Mr. Wilson said his own view was that, so far as the Council's immediate requirements were concerned, it was not a matter of importance whether gas or steam were used; but if in the future the demand increased to such an extent that they had to put down engines of double size, it became imperative that steam should be used. Mr. Prentice was naturally anxious to reproduce the gas plant, and his reason was very obvious. He had used a gas plant satisfactorily for some time, and his men understood the working of it. But the way in which Mr. Prentice proposed to increase the plant was to his mind a method absolutely impossible from the point of view of the Council. Of course, they were liable to get into difficulties with regard to smoke and vibration if they used the present style of gas-engine. In view of this it was proposed to put in vertical reciprocating engines, but there was no engine on the market which in practice achieved the results guaranteed. It seemed to him, therefore, not right that the Council should go in for something which had not got beyond the experimental stage. Messrs. Fielding and Son, of Gloucester, however, were willing to give every opportunity for testing one of their engines, and if it was not satisfactory they would take it back and let it be used on the hire system for six months. From the Council's point of view that was not satisfactory, because for the purpose of the gas-engine it would be necessary to acquire a gas producer, which could not be returned in the event of the engine proving unsatisfactory, and the Council would be bound to continue the extensions in gas instead of steam. His conclusion was that the capital expended and working expenses would be less in using steam for the extension. If the Council were in agreement with him on this point, he would ask them to instruct him to prepare specifications and obtain tenders for a compound high-pressure 100-kw. (200-h.p.) engine, with all necessary boilers, additional buildings, etc. The shaft would burn smokeless coal and consume its own smoke. The Council decided that steam be the method adopted.

Ayr.—For the first time since the introduction of the electric light, some eight years ago, last year's account closes with a credit balance of £300, which has been placed to the credit of the police rate. With regard to motor charges, it has been agreed that a universal charge of 2d. per unit should be made, with a minimum charge of £2 per annum; supplies in large quantities to be a matter of agreement with each consumer. Consumers will be required to meet the wishes of the Corporation regarding the hours of use during the winter season. The Ailsa Shipbuilding Company, Limited, are to be supplied at the rate of 1¾d. per unit for all units consumed from a minimum of 25,000 up to 40,000 units per annum, and 1½d. per unit for all units consumed if the consumpt exceeds 40,000 units; an agreement is to be entered into for a supply for at least five years. In the event of an agreement with the company being arrived at, the present cable will be extended at a cost of about £350. The annual report of the burgh electrical engineer (Mr. Roland Marshall) states that the total number of consumers connected up to the end of the year was 681, as against a total of 530 last year, thus showing an exceedingly satisfactory increase of 151 for the year, and representing an increase in the number of lamps connected amounting to 4,080, as against 2,746 last year. During the year three motors, equal to a total of 11½ h.p., were connected, bringing the total number connected up to eight, having a total equivalent horse-power of 28·5, and 26 additional arc lamps and six incandescents, making a total of 121 arc and 155 incandescent public lamps. During the year there has been no hitch in the supply of power to the tramways, and they have been supplied with 335,842 units. The following figures were added: Number of units sold—private lighting, 1902-03 253,332, 1901-02 192.553; public lighting, 424,600 (350,560); power (included in private lighting), 14,462; traction, 335,842 (132,405)—total units sold, 1,014,774 (655,518); maximum load, 548 kw. (387 kw.); coal consumed, 7,300 tons (4,963 tons); price paid for same, 7s. (6s. 8d.). In connection with the total units sold, it is interesting to note that the station supplied some 200,000 units more than any other town in Great Britain having the same population. The following was the financial result: capital expended, 1902-03 £83,510, 1901-02 £78,999; revenue from private lighting, £4,864. 3s. 4d. (£2,765. 6s. 4d.); revenue from public lighting, £3,546. 13s. 4d. (£2,147. 10s.); revenue from traction (eight months' run), £1,950 6s. 6d. (£827. 10s. 7d.); revenue from other sources, £249. 7s. 9d. (£233. 9s. 3d.)—total, £10,610. 10s. 11d. (£6,973. 16s. 2d.); total expenditure, £5,884. 2s. 1d. (£4,483. 3s. 9d.); gross surplus, £4,726. 8s. 10d. (£2,490. 12s. 5d.); interest and sinking fund, £4,425. 13s. 9d. (£3,247. 4s. 3d.); £300. 15s. 1d. net profit (£756. 11s. 10d. deficit).

Erith.—With reference to the application of the Council for sanction to the borrowing of the sum of £20,000 for electric lighting purposes, stating that the Local Government Board have decided to comply with the application so far as it related to the borrowing of £19,733, the committee have also considered the report of Mr. Hawtayne, the consulting electrical engineer, upon the advisability of providing additional plant at the electricity works. Included in the further loan of £19,733 sanctioned is the sum of £5,000 for additional plant, made up as follows: one 10,000lb. evaporation boiler, including foundations and brickwork setting, £1,400; one 300-kw. steam alternator, including exciter and foundations, £3,000; pipework for above, £320; switchgear for steam alternator and cable connection, £280. The maximum load at the electricity works up to the present time has been 130 kw., and Messrs. Callender's requirements will bring this load up to about 200 kw. There are, further, some 2,000 8-c.p. lamps waiting to be connected, which will represent another 35 kw. on at one time, so that it is anticipated that the maximum load during this winter will at least reach 250 kw. The capacity of the plant at present installed, not allowing for any spare plant, amounts to 350 kw., or, in other words, if the above load is reached during the winter there will theoretically only be 100 kw. in reserve, but in practice to do the 250 kw. it will be necessary to run the two 150-kw. sets, and if one of these breaks down there will only be 200 kw. available to meet the above requirements. Mr. Hawtayne recommends, in view of the future possibilities of the electricity undertaking, taking into consideration the tramways as well as the lighting and power loads to be anticipated, that additional plant of 500 kw. capacity should be installed in place of the 300 kw. included in the above estimate, the estimated cost of the larger plant, including additional condenser, amounting to £8,230. As the question of the size of the additional plant to be installed is in a large degree dependent on whether the Council will proceed forthwith with their tramway undertaking, the committee recommends that this matter of additional plant be considered by the General Purposes Committee of the Council, when the question as to proceeding with the tramway has been decided. The committee has received a full report from Mr. Hawtayne upon the transformers, particularly as to the causes for the breakdowns which have from time to time taken place. Mr. Hawtayne states that after carefully considering the full history of the case, he does not feel justified in altering his original opinion that the type of transformer as installed at Erith is upon the whole the best obtainable. The supply of current to Messrs. Callender's works was commenced on the 17th ult. The committee recommends that an ornamental iron kiosk be erected for a transformer station on the site of the drinking fountain, and that the surveyor be instructed to submit plans and estimates for such building. The committee have also instructed the resident electrical engineer to proceed with the wiring and fitting of the Erith mortuary for electric lighting, the same to be connected for the present to the public lighting main.

PROVISIONAL PATENTS, 1903.

SEPT. 7.

19200. An automatic lifeguard to be applied to electric tramcars. Harry Lambelle, 5, Grosvenor-terrace, Middlesbrough. (Complete specification.)

19249. Electric controlling apparatus. Carl Ewald Schönfelder, 27, Chancery-lane, London.

19250. Improvements in telephone receiver holders. Arthur Joseph Briggs, Fife House, Kingston-on-Thames. (Date applied for under Patents Act, 1901, Sept. 6, 1902, being date of application in United States.) (Complete specification.)

19251. Improvements relating to electric telegraphy. Sidney George Brown, 45, Southampton-buildings, Chancery-lane, London.

SEPT. 8.

19291. Improvements in the electric extraction of sodium, potassium, and the alkaline metals. Edwin Thornley Parker, Lea-road, Wolverhampton.

19319. A cell recorder for use in electric light stations and other places. Arthur James Abraham, 37, West Nile-street, Glasgow.

19363. Improvements in or relating to electric insulated cables. Henry Robert Garrard, 6, Lord-street, Liverpool.

19366. Process relating to the reducing of metallic compounds and the fusing of metals, in particular of nickel and iron, in the electric furnace. Charles Denton Abel, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Siemens und Halske Aktien-Gesellschaft, Germany.)

19367. An improvement in the insulation of electric conductors. Edward Lawley Pinching and Walter Henry Walton, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

19368. An improvement in the electrode deposition of copper. Harry Parkes, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London.

SEPT. 9.

19399. Improvements in pipe sockets or couplings, more especially for the purpose of facilitating inspection when used with pipes which contain electric wiring. Ernest White and James Waldron, Prince's-chambers, Wolverhampton. (Complete specification.)

19419. Improvements in high-frequency electrical appliances. Leslie Bradley Miller, 93, Hatton-garden, London.

19427. An improved mechanical electrical switch for use on tramways and light railways, worked on a surface-contact system. Joseph Patrick Trumble and Thomas Meredith Trumble, 540, Romford-road, Forest Gate, London.

19437. Improvements in raising and lowering electric arc lamps. William Anderson Brown, 40, Chancery-lane, London.

19449. Improvements in apparatus for reducing or preventing the production of sparks at the collectors of dynamos and electric motors. Reny Thury, 45, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Oct. 16, 1902, being date of application in Switzerland.) (Complete specification.)

Digitized by Google

19454. Operating vapour electric lamps from an alternating-current source. Ezechiel Weintraub, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, Oct. 18, 1902, being date of application in United States.) (Complete specification.)

SEPT. 10.

19491. Improvements in and relating to arc lamps. Charles Edwin Foster, Edwin Rudolp Grote, and Milton Victor Ely, 165, Queen Victoria-street, London.

19492. Improvements in apparatus for controlling and operating the points of electric railways and tramways. John Garside Lees, 8, Quality-court, Chancery-lane, London.

19513. Improvements in and relating to underground current conductors and surface rail contacts for electric street railways. Anton Kuchinka, 72, Cannon-street, London.

19520. Improvements in alternating-current electrical apparatus. Charles Fenton Scott, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 13, 1902, being date of application in United States.) (Complete specification.)

19521. Improvements in systems of alternating-current distribution for railways. Charles Felton Scott, Westinghouse-building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, Sept. 13, 1902, being date of application in United States. (Complete specification.)

19522. Improvements in rotary electric machines. Henry Chitty, Westinghouse-building, Norfolk-street, Strand, London.

19524. Improvements in manhole terminals for conduit sections. Guy Moore Gest, 40, Chancery-lane, London. (Complete specification.)

19540. Improvements in electrically operated and controlled railway signals. Robert Drury Peters and Hjalmer Andrew Ellingson, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

19547. Improvements in or relating to the magnetic excitation of synchronous, alternate, and three-phase current machines. William Phillips Thompson, 322, High Holborn, London (Berliner-Maschinenbau-Actien-Gesellschaft vormals L. Schwartzkopff, Germany.) (Complete specification.)

19533. Improvements in and relating to printing telegraph apparatus. Henry Casevitz, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, Sept. 11, 1902, being date of application in France. (Complete specification.)

SEPT. 11.

19633. Improvements in apparatus suitable for detecting electric, Hertzian, or similar waves or currents. John Reed Fothergill and Henry Fothergill, 46, Lincoln's-inn-fields, London.

SEPT. 12.

19657. Improvements in and relating to the working of points and plough guides on electric cable tramways or railways. William James Stewart, 96, Buchanan-street, Glasgow.

19705. Improvements in turbines. Willans and Robinson, Limited, and Matthew Henry Phineas Riall Sankey, 24, Southampton-buildings, Chancery-lane, London.

COMPLETE SPECIFICATIONS ACCEPTED.

To be published Oct. 1, 1903.

1902.

19366. Electric cable conductors. Hitch.

19573. Contact shoes for electric railways. Lake. (General Electric Company.)

19579. Process and apparatus for the detection of short-circuits in electric batteries. Beckmann.

20323. Electric switches. Codd.

20556. Electromagnetic valve-controlling apparatus. Waterman.

20656. Switches and connections for testing electric current circuits. Addenbrooke and Robinson.

21267. Secret electrical interrupter. Zay.

21302. Electric lampholders. Chalmers.

22957. Construction of electric switch. Schulz.

23114. Storage and other batteries. Niblett.

23115. Current or charge meters or indicators for use chiefly in connection with storage batteries. Niblett.

23151. Battery installation for submarine boats. Lake.

23560. Trolley gear for electric traction. Bushell.

23940. Electrical influence machines. Eckstein and Coates.

24101. Methods of and apparatus for transforming electric energy. Carolan. (General Electric Company.)

24172. Conduit system of electric traction. Galloway.

24236. Process for obtaining metallic sulphides in electric furnaces. Bronn.

24644. Field magnets of dynamo-electric machines. Burleigh.

24330. Apparatus for the generation and application of electric currents for electrolysis. Elmore.

24711. Magnet coil spools. Carolan. (General Electric Company.)

25442. Secondary electrodes for electrolytic apparatus, more especially intended for use in the manufacture of chlorates. Imhoff and United Alkali Company, Limited.

28523. Electric accumulators. Haddan. (Soc. Française de l'Accumulateur Tudor.)

1903.

7337. Terminals for secondary or electrical storage batteries. Tunbridge.

12301. Electric meters. Compagnie Anonyme Continentale pour la Fabrication des Compteurs à gaz et Autres Appareils. (Date applied for under International Convention, Oct. 4, 1901.)

13983. Induction coils. Splitdorf. (Date applied for under International Convention, April 8, 1903.)

14940. Device for indicating the exceeding of specified speeds on dynamos, motorcars, and the like. Neuberg.

15338. Magneto-electric igniting apparatus for internal-combustion engines. Roos.

15992. Electromagnetic brake for electrically-propelled cars of tramways and street railways. Seggel.

16653. Apparatus for soldering armature leads to commutator bars. Wirth and Beech. (Date applied for under International Convention, Oct. 22, 1902.)

16806. Holding devices for the collecting brushes of electrical machines. Brewer. (Elecktricitäts-Gesellschaft Alioth.)

NOTES.

Electric Speed Trials.—Further speed trials on the electric railway between Berlin and Zossen are reported by Reuter to have resulted in a speed of nearly 114 miles an hour being attained. This is a great improvement on what has been previously achieved, the highest record having been 100 miles an hour. There seems every prospect of the much-talked-of 120 miles an hour being attained before very long.

The Pacific Cable.—A dispatch from Ottawa states that Lord Strathcona has conferred with Sir W. Mulock, the Dominion Postmaster-General, with regard to the land-line rates between Canada and Australia, which are said to be so high as to militate against the business of the Pacific Cable. Sir W. Mulock was unable to promise relief, as the Government exercise only a nominal control over the rates of the telegraph lines.

London-Paris Telephone.—Further facilities are being offered in connection with this line. Soon it will be possible to use the telephone between London and Paris during the night at half the existing rates. Eight shillings for every three minutes is at present the charge at all times during the day. When the contemplated arrangements are completed it will be possible to telephone between the two capitals during the night for 4s. per "conversation," provided that a monthly subscription is made for a period of not less than six minutes per night.

Telegraph Statistics.—From the "Statistical Year Book" of the German Empire we take the following comparative figures: In 1900 Germany had 24,471 telegraph offices, with 36,000 instruments in operation; Great Britain, 11,512 offices and 38,000 instruments, and the United States, 22,954 offices and 81,000 instruments. The number of telegraphic dispatches transmitted in 1900 was: Great Britain, 92,000,000; United States, 63,000,000; France, 50,000,000; Germany, 46,000,000. In Germany there were 2,411 cities or or towns having public municipal telephone systems, with 305,795 connections. France had 1,199 public telephone plants, with 72,480 connections.

Telephonic Communication with Belgium.—On Oct. 1 the existing telephone service between London and Brussels will be extended, and communication can be obtained by subscribers to the Post Office telephone system between the Central, Western, Victoria, and Putney exchanges in London and Antwerp, Bruges, Charleroi, Ghent, Liège, Louvain, Malines, Mons, Namur, Ostend, Termonde, and Verviers. Communication will at the same time be opened between Birmingham, Brighton, Bristol, Cambridge, Cardiff, Derby, Ipswich, Leicester, Lowestoft, Newport (Mon.), Norwich, Nottingham, Sheffield, Southampton, and Yarmouth, on the one hand, and Brussels and certain of the above-mentioned Belgian towns on the other. In all cases the charge will be 8s. for a conversation of three minutes.

Electro-Harmonic Society.—We have pleasure in announcing the arrangements which have been made by the above society for the ensuing season, which is the eighteenth of its existence. The programme provides for four smoking concerts—on Oct. 9, Dec. 18, Jan. 22, and March 25—and two ladies' nights—on Nov. 13 and Feb. 26 respectively. As was the case last season, the rendezvous will be the Holborn Restaurant, and in anticipation of crowded audiences the two ladies' concerts will be held in the King's Hall. A pleasing echo of the last season is the publication in the society's latest circular of a letter from Mr. J. C. Lamb, C.B., C.M.G., president of the recent International Telegraph Conference, recording the delegates' thanks for the pleasant evening arranged for them on the occasion of the special extra concert on June 5.

Unique Electric Trolley Scheme.—We hear of a scheme which is progressing favourably in the States, and which proposes an unusual example of electric railway construction. The idea is to build a trolley line in the bed of the Morris Canal from Newark to Paterson, a distance of about 12 miles. The result, it is expected, will be an actual saving of thousands of pounds, and, as the canal is at present being worked at a loss, it is in the interests of economy that the scheme should be allowed to proceed. A somewhat parallel case occurred in this country some years ago, when that part of the Gravesend-Strood Canal which ran through tunnel was acquired by the South-Eastern Railway Company. At the present time a considerable part of the railway from Gravesend to Chatham is laid on the bed of the disused canal, and the tunnel, which one time marked the course of a busy barge traffic, is given over to the purposes of a not less active steam railway service.

Incandescent Lamp Combine.—News reaches us from the Continent that the rumoured formation of a syndicate of makers of incandescent electric lamps in Europe is assured. It is stated that the negotiations on the subject have been in progress for a long time past, but the difficulties which have arisen in apportioning the production of each manufacturing company have hitherto prevented the scheme from being brought to a successful conclusion. Now an estimate has been brought forward that the output of the works proposing to form the syndicate amounted to 27,500,000 lamps last year, and it is on the basis of this computation that the constitution of the combination is projected. Among the German, Austrian, and other companies said to be interested are the Allgemeine Elektricitäts-Gesellschaft, of Berlin, the United Electricity Company, of Vienna, the Siemens and Halske Company, of Berlin, Strum and Co., of Vienna, and other factories. The proposed combination is for 10 years, and the anticipation is that its formation will immediately result in a standard of prices being fixed at a considerably higher level than exists at present.

Books Received.—"Conduction of Electricity Through Gases," by J. J. Thomson, D.Sc., LL.D., etc. (Messrs. C. J. Clay and Sons). In this work the author developes the view that the conduction of electricity through gases is due to the presence in the gas of small particles charged with electricity called ions, which, under the influence of electric forces, move from one part of the gas to another. The author declares his object to have been to show how the various phenomena exhibited when electricity passes through gases can be co-ordinated by this conception, rather than to attempt to give a complete account of the very numerous investigations which have been made on the electrical properties of gases. The book contains the subject-matter of lectures given at the Cavendish Laboratory, where a good deal of attention has been paid to the subject, and where a considerable number of physicists are working at it.—"Electricity and Magnetism," by R. T. Glazebrook, M.A., F.R.S. (Messrs. C. J. Clay and Sons); 7s. 6d. As implied by the title, this is a work dealing with elementary electricity. To a large extent it embodies the subject-matter of lectures delivered at one time or another by Dr. Glazebrook, and although originally intended for the benefit of students at the Cavendish Laboratory, the author expresses the hope that it will be found of service outside that immediate sphere.

Ozone Production.—High-frequency resonators, as is known, give rise to an abundant production of ozone. According to Bordier's experiments, this means of pro-

Digitized by Google

duction is much preferable to any other method, dark discharges being much more efficient than luminous ones. In the neighbourhood of high-frequency resonators there is thus a field particularly favourable for the transformation of oxygen into ozone, the energy maximum of this field coinciding with the terminals of the secondary. In a note recently read before the French Academy of Science, M. Guillemiot describes an ozoniser which is a particular application of such high-frequency coils. Two coils are connected in parallel and placed in front of one another, being surrounded by a flexible impermeable substance, whereas the external faces are provided with glass plates so as to form an air vessel, the transparent sides of which enable the state of the discharge to be observed from outside. All sorts of devices may, moreover, be easily designed in order to regulate the distance of the coils to change the faces placed in front of one another and to alter the self-induction of the primary coil. Air is then passed through the vessel. The most suitable condition for continuous renewing of the air layers is thus ensured, this condition being favourable to the output of any high-frequency ozonisers. The advantages of the type of coils above described are as follows: first, that they allow of the enormous mutual influence of the resonators being utilised to augment the field, and, second, that they permit of a large discharge surface being obtained between two resonators.

New Form of Mirror Extensometer.—Mirror extensometers have not been much used in this country. They are not self-contained, and to obtain the mean extension of a specimen two sets of readings are necessary. There may be errors due to slight alterations in the positions of the specimen, the telescope, or the scale. Mr. John Morrow, before the engineering section of the British Association, described an experiment in which an attempt has been made to avoid these defects and to obtain the mean extension by a single observation. Its special feature is the use of two mirrors placed side by side, one of which is attached rigidly to the instrument and the other arranged to tilt about a horizontal line when the specimen extends. The tilting mirror is carried on a piece of hardened steel of diamond-shaped section. One edge of this base is pressed against a piece attached to the upper pair of set-screws, and the opposite edge similarly against a piece from the lower screws. The four set-screws serve to attach the instrument to the specimen, and are situated at opposite ends of two parallel diameters of the test piece. Any change in the mean vertical distance between them is thus a measure of the alteration in length of the centre line of the specimen, and is accompanied by a slight tilting of the mirror. A telescope is so placed that the two images of a scale are seen close together, and to measure extensions a convenient mark on the fixed image is taken as an index, and the reading coinciding with it on the other image is noted each time the load is altered. The instrument has proved very satisfactory with a magnification of 1,600, when the extensions can be measured to the nearest $\frac{1}{640000}$ of an inch.

Protection of Wood.—Any device, method, or process which tends to the protection of wood from fire and its preservation from decay should be welcomed by engineers, as opening up a question of supreme importance which has never yet been completely solved. An hour added to the time necessary to render wood inflammable when exposed to fire, as in the case of the recent Paris Tube disaster, represents a real increase in commercial value, and herein lies the importance of a paper on the subject read by Mr. Ferrell before the Engineers' Club of Philadelphia. He describes two recent discoveries which represent a distinct advance in entirely doing away with the steaming process commonly employed for drawing out the sap from timber. The wood to be treated is placed in a cylinder; a piston, with an aperture in its centre, advances against one end and presses the other against a rubber cushion on the closed door of the case, this cushion also having a similar aperture in its centre. Zinc sulphate is then forced in at one end, driving the liquid sap before it and out at the other. The outlet is then closed, and continued pressure forces the zinc sulphate solution, by way of medullary rays, throughout the whole mass towards the surface. The cylinder is then filled with calcium chloride under pressure. This, penetrating far into the wood, reacts on the zinc sulphate to produce the preservative zinc chloride, enveloped and penned in by the almost insoluble calcium sulphate. This double reaction, consisting of the formation of an insoluble guard to prevent loss of the preservative salt, constitutes the chief feature of the process. For fire-proofing aluminium sulphate is used. Exposure to fire causes the disengagement of water and sulphur dioxide, retarding combustion pretty much as it would in the case of ammonium sulphate, but instead of this stage ending the protection, there is a residue of alumina left which has the excellent property of swelling to nearly three times the volume of the dry sulphate, and, being an admirable non-conductor, enables the mass to withstand fire for a prolonged period.

Oil Fuel.—The increasing interest and steady progress in the employment of oil as fuel for various purposes suggested the compilation of a paper, which Mr. A. M. Bell read before the Engineering Section of the British Association at Southport. He showed at the outset how the large discoveries in Californian and Texas have provided enormous supplies of crude oil, and have led to great advances being made in its use in the United States. Owing to the absence of regular supplies progress in this country has not been so rapid. The manufacture of oil gas and carburetted water gas has, however, thrown on the market products of a character only suitable for fuel, and rendered its adoption possible on a limited scale. The different methods of burning oil fuel may be summarised as follows: (1) those wherein it is burned in bulk form; (2) in a sprayed or atomised condition; and (3) consumed as vapour or gas. The first-mentioned procedure has received most application in Russia, whereas the last has enlisted most attention in the United States owing to the lighter character of the oils available. Generally, however, the second or spraying system may be looked upon as the favourite, most generally adopted, and probably the most successful; hence the chief attempts at improvement appear to have been devoted to it. The most effective device is doubtless that requiring the least quantity of the atomising agent (steam or compressed air) for operation, and until recently the attention of workers in this direction has been centred on the burner employed, the construction of the furnace, which is of as much importance for a good result, being somewhat neglected. Further, a due consideration of the admittance, distribution, and temperature of the air for combustion is absolutely essential to success. The latest developments of spraying apparatus point to the employment of oil fuel under pressure, heated to a high temperature, sprayed with dry steam, and the fire fed with heated air for combustion. For furnace work oil fuel offers unique advantages, and many interesting applications have been made to meet the special requirements of annealing, tempering, metal melting, brazing, etc. In glassmaking and enamelling oil fuel has met with considerable adoption, and portable

Digitized by Google

furnaces of all kinds are successfully operated with it; in bridge-work, shipbuilding, etc., oil-fired rivet furnaces are to be preferred to any form of solid fuel-heating device. In storage oil fuel has many favourable features. It occupies a minimum of space, does not deteriorate by exposure, and is easier of transportation and distribution. In the Far East and many Oriental countries the importation of oil fuel has now become a regular undertaking, and supplies are guaranteed in many cases where wood has become scarce and imported coal an almost prohibitive article.

Northampton Institute. — Dr. R. Mullineux Walmsley, the principal of the above polytechnic, informs us that the 1903-4 session will open as regards evening courses and classes in engineering, artistic crafts, and other technological subjects on Monday, the 28th inst., and as regards day courses in engineering on Monday, Oct. 5. Many of our readers will be familiar with the excellent work which the Northampton Institute is achieving under the able administration of Dr. Walmsley and the governing body, of which the Marquis of Northampton is the chief private member. A bulky prospectus has reached us setting forth the programme of announcements, educational and social, for the coming session, and we compliment the compilers on its excellent get-up. We are very interested to find that the engineering subjects are chief factors in the courses of instruction. We will, however, confine our attention to the purely electrical engineering branch, with which our readers are concerned more particularly. This department has the inestimable advantage of having Dr. Walmsley himself at its head, with Dr. C. V. Drysdale as chief assistant and senior lecturer. Its work is divided into four branches—*i.e.*, lectures, laboratory work, workshop practice, and special drawing-office work in the design of electrical machinery and apparatus. In glancing through the prospectus one is struck by the large amount of practical instruction which is given in the workshops and laboratories, and this will particularly appeal to the electrical student. Electro-chemistry and electro-metallurgy are taught in conjunction with the electrical engineering department, and only electrical students may attend the classes. The electro-chemical laboratory, on account of the electro-chemical trades carried on in the neighbourhood of the institute, has been fitted up in a very complete manner with current-generating apparatus, secondary batteries, and depositing vats for hot and cold work, in which all the usual processes for the electro-deposition of metals can be carried out on a commercial scale and under ordinary workshop conditions. In view of the present rapid development of the electro-chemical industry, the practical training in the subject should be especially valuable to electrical engineering students.

The Acker Process for Alkali.—Mr. Chas. E. Acker's process for alkali and bleaching powder by the electrolysis of fused common salt has gained the Elliott-Cresson Medal of the Franklin Institute. The committee which examined into the merits of the process has published its report which, while commending the operation as a "commercial practicability," throws out one or two hints for the guidance of the inventor in his future work. The report is not an unqualified approval of Mr. Acker's method; it is in a more critical strain, and, therefore, the more interesting. The details of the process and its operation have been widely published, and the committee is satisfied that the information given to the world is substantially correct; and from the facts submitted to the committee it appears that the business can be operated profitably at present market values of the products and at the cost of power at Niagara Falls. As compared with the wet electrolytic processes the advantages of the Acker system are summarised thus: First, its directness, the salt being decomposed in one room, the whole process being completed in two operations and in a space of about 30ft. A second advantage is the very heavy current sent through each pot—as much through one Acker pot as through 15 Castner cells; a third, the absence of the evaporation of caustic and boiling down to dryness; a fourth, the absence of water solutions, requiring special pumps and a complicated circulating system; and, finally, the absence of the use of mercury. Among its disadvantages are a larger power requirement—6·75 volts in place of 4·5, or some 50 per cent. more; the rapid destruction of the apparatus and of the anodes; and the more arduous work of the potmen. As regards the future advancement of the process, the committee says there are still improvements possible in the working of the plant, particularly regarding the durability of the pots and the simplification and better preservation of the anodes. Their presence and evident capability of improvement give hopes for a still better working of the process. Some calculations made by the committee may be of scientific and practical interest. Of the total energy of the current used, 54 per cent. is usefully applied to the chemical separation of sodium from chlorine, 9 per cent. is utilised in melting the salt used, and 37 per cent. is radiated from the apparatus. As regards the quality of the products, the committee found the bleaching powder to be substantially as given by Mr. Acker's analysis, but that the caustic soda, while of good commercial quality, contained more sodium chloride and carbonate, and less caustic soda than shown by the analysis. In view of this the committee recommend Mr. Acker to exercise more care to prevent carbonation, and particularly the entrance of sodium chloride accidentally into the fused caustic during its collection in the pot-room.

South African Inter-Town Telephones.—For some time past the Post Office Department of the Cape Government has had under consideration the question of inter-town telephonic communication, and developments in this direction are to be shortly expected. Briefly, the scheme is not only to connect up the larger towns in Cape Colony by telephone, but to establish connections with other important centres in South Africa, such as Johannesburg. Sir Somerset French, the Postmaster-General at the Cape, has made a report on the scheme, from which it seems that the department is at present making experiments with a view of determining the minimum weight of copper wire which would be necessary to secure clear telephonic speech during working hours over long distances under the conditions prevailing in South Africa, having regard to the disturbing effect of the powerful electric currents employed on the telegraph lines in connection with Wheatstone automatic telegraph working, and to the inductive effect of the phonopore instruments used for railway signalling. These experiments are being made before any reliable estimate can be formed of the type of line which would be necessary for long-distance telephony. Conditions vary in different countries, and the consulting engineer to the Government, Sir William Preece, has stated that the weight of copper wire to be used can only be decided by practical test. The weight of copper wire ordinarily used varies according to distance from 150lb. to 800lb. a mile, and two wires are required for each line. For long distances Sir William Preece does not advise a lesser weight than 800lb. (or 1,600lb. for each speaking circuit per mile) unless climate and other conditions conclusively show that a lighter gauge would give effective results. It is expected, however, that in South Africa the electrical and climatic

Digitized by Google

conditions will prove more favourable than in Europe and America, and that even for the longest distances the weight of copper can, without serious risk of failure, be reduced. Owing to the large number of wires that would be required, and also to avoid interruptions, Sir S. French says that a separate system of poles from the telegraphs would be required. The main trunk line would be between Cape Town and Beaufort West, linking in the intermediate towns of importance, and he estimates that the total cost of this section would be over £200,000. The charges for conversations would necessarily have to be high as compared with telegraph rates, and Sir S. French thinks the annual expenditure for maintenance would be a heavy item. However, the scheme is to await the result of the experiments which are now going on; but, incidentally, parliamentary sanction is about to be sought for the money provision required for the establishment of telephone exchanges at a number of towns in the Colony. Until these are in operation it is not expected that a trunk system could be conveniently used. As soon as is possible, however, estimates of cost will be prepared and a general scheme placed before the South African Government, which will doubtless be fully discussed in Parliament.

Coal Storage under Water.—The best method of preserving the working power of steam coal is a subject of considerable importance to the engineer without distinction of class. It has been stated that a steamship will have to consume more than twice the normal amount of coal per indicated horse-power if the coal has been kept in store for, say, six months. Whether this may be taken as a true exposition of the case or not, it will be admitted that the storage of coal for considerable periods results generally in a lowering of its calorific value. The subject is revived by a pamphlet we have received from Mr. John Macaulay, general manager of the Alexandra Docks and Railway, Newport, Mon., in which he gives his views of the case, based on experiment and practical experience. Mr. Macaulay's experiments have been directed particularly to the determination of the beneficial results obtaining from storing coal under water. He had an experimental quantity of coal placed under sea-water in a suitable vessel and special manner for two months. At the end of the time an estimation was made of its calorific power and compared with one made of the coal before immersion, both samples being of Monmouthshire steam coal. The loss was found to be less than 1 per cent., or, to be accurate, ·8075. This appears to be very small, but even if far larger, it would compare very favourably with the loss of power arising from the present method of storing. Some further experiments on a more extensive scale were afterwards made by Mr. Macaulay with four varieties of coal—*i.e.*, the best Monmouthshire, coal that had been three years under water, coal that had been 10 years submerged, and coal recovered outside the mouth of the River Usk or "river" coal. The order of value in steam raising and actual working results in which these coals came out in the tests was: first, the "river" coal; second, the coal that had been under water 10 years; third, fresh coal; and fourth, coal that had been three years under water. Comparing values with the fresh or test coal, the "river" coal was 4 per cent. better, and that which had been under water 10 years 1·8 per cent. That which had been under water three years had lost 1·6 per cent. of working power. From his experiments, Mr. Macaulay is able to arrive at several broad conclusions, first among which is that steam coal loses very little of its power by submersion under water for the length of time it would be reasonably kept in naval storage. Storage in a concrete reservoir holding, say, 250,000 tons would offer the following advantages: first, cheapness; and, second, the coal could be easily got at when used, as all that would be necessary would be to pump the sea-water out of the reservoir. Assuming the salt in sea-water to be accountable in a measure for the improvement in long submerged coals, it is suggested that the addition of more salt to ordinary salt water would improve coal submerged for less lengthy periods. But Mr. Macaulay is pursuing his experiments upon a larger scale, and we may expect to hear more of the subject before long.

Aluminium Conductors.—On this subject there were two contributions to the proceedings in Section G of the recent Southport meeting of the British Association. The first was submitted by Mr. J. B. C. Kershaw under the title "Aluminium as an Electrical Conductor"; the other by Prof. Ernest Wilson on "The Electrical Conductivity of certain Aluminium Alloys as affected by Exposure to London Atmosphere." In both these papers the authors describe experiments made with aluminium rods and wires under exposure to the atmosphere, but the conclusions obtained in each case are in directly opposite directions. Mr. Kershaw's paper may be taken as a continuation of that read before the Institution of Electrical Engineers in January, 1901, as it records the results of further tests made at Waterloo, in Lancs., since that date. Summarising these results, Mr. Kershaw says that all the samples of aluminium gained in weight during exposure, and that all were pitted and corroded, especially on the underside, where the water drops had collected and dried. He regards it as only a fair deduction from these exposure tests that aluminium manufacturers have yet to prove the metal a satisfactory and desirable substitute for copper in bare overhead transmission lines, or for electrical work which involves exposure to climates near the sea coast. Turning to the other point of view as expressed in the second paper, we find that Prof. Wilson carried out his tests in the neighbourhood of King's College, London. The results obtained up to July, 1902, have been communicated to the Institution of Electrical Engineers, and the present paper gives the results of another year's exposure of specimens of certain alloys of aluminium on the roof of King's College. It was shown in the previous paper that during the first year's exposure the series of copper-aluminium alloys (Nos. 16, 4, 13, 14, 15) diminished conductivity to a greater extent the greater the percentage of copper. It is seen from the table which accompanies the present paper that this process has progressed still further, but that the variation during 1902-3, expressed as a percentage of the value found in 1902, is smaller than the corresponding quantity in 1901-2. In the 1902 communication it was shown that alloys No. 21, 22 had not diminished conductivity by exposure. They have now done so. On the other hand, alloy No. 23 has not changed during 1902-3; whereas it diminished conductivity 2·34 per cent. during 1901-2. The Mn series (Nos. 9, 10, 23) have changed very little, and No. 23 has a comparatively high breaking load of 35,300lb. per square inch. The Ni series (Nos. 7, 8, 20) have also changed very little during 1902-3. For exposed light aluminium alloys the results confirm the conclusion previously arrived at—namely, that copper alone should not be used in comparatively large quantity. In the discussion which followed the reading of these papers, it appeared that the differences in the results obtained by the two authors were fairly accounted for by the differences in the composition of the materials actually used. The wires experimented with by Mr. Kershaw have a very considerable percentage of other metals—about 5 per cent.—whereas those exposed by Prof. Wilson in London were

Digitized by Google

much more pure. It would appear, therefore, that the corrosion, as was to be expected, is largely influenced by the composition of the aluminium. It also seems from Prof. Wilson's figures than the rate of corrosion decreases with time.

Telephone Wayleaves.—Although ranking among the most progressive places in the country, Birmingham is one of those towns which have not yet taken up the telephone as a municipal question. Its citizens remain dependent for local telephonic communication on the National Company and its wiles and favours. The fanciful methods of the company are pretty well known, and probably our readers will not be unduly astonished at the following little episode which is told in one of the Birmingham dailies. A solicitor of that city applied to have his office connected to the company's system, and the company sent him a form of contract containing a condition that he was to allow the company to acquire "all such wayleaves for poles, wires, and other appliances on or over any property as the company in its sole discretion considered necessary." While ready to offer all reasonable assistance and facilities to the company on his own present property, he objected to the wayleaves applying to property "under his control" as agent or trustee, and also to leaving the wayleaves to "the sole discretion" of the company. On the first point the company offered to give way, but declined to recede on the question of discretion. Representations were made by the solicitor to the Postmaster-General, who replied that there was no ground on which he could intervene. The matter, however, was apparently further considered by Mr. Chamberlain, and a second letter from his private secretary to the Birmingham solicitor shows how completely powerless the Post Office is to see fair play as between the Telephone Company and its subscribers. Mr. Chamberlain agrees that the stipulation which the company has attempted to enforce in this case is contrary to the public interest, but declares that he has "no power, either as member of Parliament or as Postmaster-General, to compel them (the company) to waive their stipulation." Mr. Chamberlain naïvely adds that, unfortunately, the circumstances were not as well understood when the National Telephone Company received its original license as they are to-day, but wherever altered circumstances give him the power to enforce new conditions precautions are now taken to guard against such extensive wayleave demands being made a condition of service. It comes to this, then, that an important monopoly having been created for the public convenience, the company may, if it suits its purpose, refuse a service by imposing conditions as to wayleaves of so stringent a character, however much opposed to the public interest, that no sane man could accept them. This course the company would appear to have successfully adopted in the Birmingham case, where a citizen is to be deprived of the benefits of the telephone because he declines to give the company an unlimited license as to wayleaves on his private property. Another instance of the company's questionable tactics is to be found in an advertisement which has appeared in some of the provincial papers in the form of news, wherein it is sought to prove that the Glasgow municipal undertaking has led to an additional tax of £5 per annum being placed on the shoulders of several thousands of citizens by inducing them to subscribe to both telephone systems. The paragraph, however, clearly shows—perhaps inadvertently—that the subscribers to the company's system are now able to communicate with some 4,000 or 5,000 persons who before the inauguration of the municipal exchange were not subscribers to the telephone. Such palpable misuse of figures does not reflect much credit on the company, although we cannot but admire the ingenuity displayed by the author in turning a handsome profit on last year's working of the Glasgow undertaking of nearly £1,700 into an apparent responsibility of £5 per head on several thousands of its citizens.

St. Marylebone Electric Lighting.—The unique case which has arisen at St. Marylebone of a municipality entering into agreement to purchase a company's business, and afterwards being unable to raise the necessary money, continues to be a subject full of interest and speculation. Unfortunately for the Marylebone Borough Council, the arbitrator's award, fixing the purchase price of the Metropolitan Electric Supply Company's undertaking in the borough at close on a million sterling, is binding, and forms the subject matter of a contract between the parties which is enforceable at law. Still more unfortunate is the fact that interest on this high sum is rapidly accumulating, and it is estimated that completion of the purchase even at the present time would cost the Municipal Council nearly a million and a quarter sterling. However, the prospects of the Council being able to raise the money at an early date are still far distant, and the situation is not much changed since we last wrote on the subject. In fairness to the Borough Council, it should be stated that it is trying every means at its disposal in an attempt to get rid of the technical difficulty which now prevents its borrowing the money required, owing to the withholding of the London County Council's consent. It was thought that if the Board of Trade would grant the Corporation a special license constituting it an electric lighting authority the situation would be saved, and the purchase completed before the end of the year. We, however, understand, although the formal decision has not yet been communicated, that the solicitors to the Board of Trade have advised that such a license should not be granted. The Borough Council is thus left with two other possible courses of action. The first is to appeal to the Local Government Board against the refusal of the London County Council to sanction the loan, and this has already been done. The appeal has been pending for some time awaiting the result of the proceedings at the Board of Trade, but now that that department has intimated its views on the subject, the decision of the Local Government Board is daily expected. The Borough Council, however, can hardly conceal from itself the fact that it stands no greater chance of success with one Government department than another, and in that case the only alternative will be an appeal to Parliament. This means further delay, as a Bill authorising the municipality to raise the money required cannot be promoted till next year, and even if passed could scarcely become law till well on towards the end of the session. It is, however, a last resourse, and be it said to the credit of the Borough Council, that it is straining every effort to meet its responsibilities in this matter. Another point which cannot fail to put further difficulties in the way of the Council is the order of Mr. Justice Buckley in the recent proceedings in the High Court, which rules that "the company are to retain the profits of the St. Marylebone undertaking in lieu of and in satisfaction of any claim due from the Borough Council for interest on the purchase money." Dec. 31 this year is named by the judge for the completion of the purchase, but the Council is to be allowed to apply for an extension of time. In the circumstances this it will, no doubt, be forced to do; but, in any case, another year's delay in the conclusion of the matter would be disastrous to the borough. At present the Council is building up hopes on the result of its appeal to the Local Government Board, but for ourselves we are unable to find any consolation on this score, and fear the worst.

THE DISTRIBUTION SYSTEM AND ITS INSTALLATION AT THE WORLD'S FAIR, ST. LOUIS, 1904.

The distribution of the 20,000 kw. electrical energy necessary for light and power purposes at the World's Fair grounds, St. Louis, requires a very extensive net of cables, starting from the main switchboard in the machinery hall and spreading all over the grounds. The main switchboard will be installed upon a gallery in the centre of the west side of the machinery hall, and has a total length of 90ft. The details of this switchboard are now entirely worked out. It will be composed of several independent switchboard panels, a practice that has come into very extensive use in the United States. Each of these switchboard panels is made up of a marble plate bearing all the apparatus for one machine set. The marble plates are kept very plain. The edges are bevelled and polished. These plates are mounted upon an iron frame, and neither the switchboard panels nor the whole main switchboard have wooden framings, and wood is entirely avoided in the construction of the switchboard. The main switchboard is composed of 29 of these switchboard panels. The 'bus bars are installed upon a separate iron frame under the switchboard, and extend the whole length of the switchboard. The 'bus bars, as well as the switches for making connections from the switchboards to the 'bus bars, are in duplicate, thus decreasing the liability of interruption to a minimum. Oil switches are employed throughout the whole switchboard, these switches having been highly perfected in the United States, which explains their extensive use.

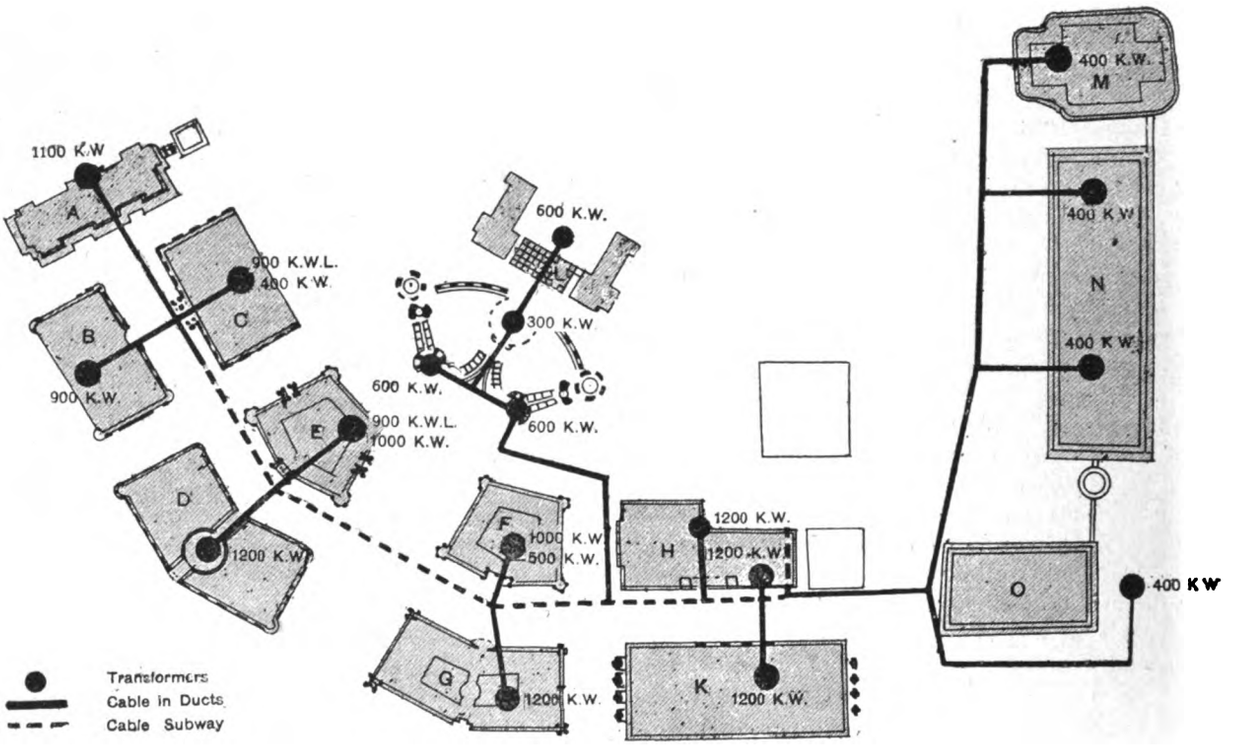

FIG. 1.—Distribution of Energy on the Grounds, World's Fair, St. Louis. A, Government; B, Liberal Arts; C, Mines and Metallurgy; D, Manufactures; E, Education and Social Economy; F, Electrical Machinery; G, Varied Industries; H, Machinery; K, Transportation; L, Fine Arts; M, Horticulture; N, Agriculture; O, French Government.

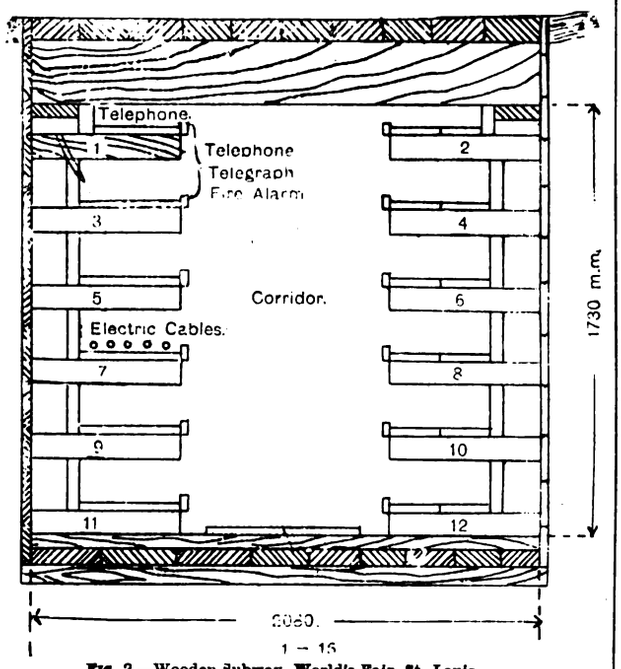

FIG. 2.—Wooden Subway, World's Fair, St. Louis.

The following voltages and current systems are available in the machinery hall and the other principal exhibit buildings: three-phase alternating current, 25 cycles per second, 6,600, 2,200, and 190 and 110 volts; two-phase alternating current, 60 cycles per second, 2,200 and 110 volts; single-phase, 60 cycles per second, alternating current, 4,000 volts; direct current, 550, 220 and 110 volts. In special cases all other voltages and current systems can be provided for the exhibitors.

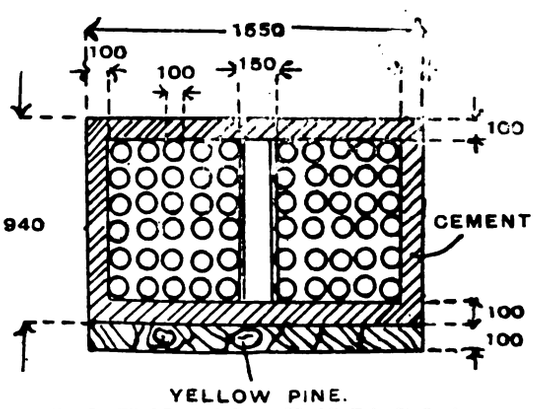

FIG. 3.—Tiled Ducts Subway, World's Fair, St. Louis.

Starting from the main switchboard, feeder cables conduct the current underground to the transformer stations. Our plan (Fig. 1) shows the way of installation and the situation and output of the transformer stations. The serrated line indicates the cables installed in the subway, the solid lines the cables installed in wood, conduits. In the transformer stations the energy provided for light is indicated by L, the energy provided for power is indicated by K. Where no indications are made the transformers serve

Digitized by Google

exclusively for lighting purposes. The cable subway (Fig. 2) is constructed of wood, and measures 8ft. by 8ft. Each five cables are installed upon wooden brackets, and space of sufficient capacity to carry 60 cables is provided. An unoccupied space of 2ft. 8in. remains between the two rows of brackets, and this serves as a corridor for repair

FIG. 4.—Tiled Ducts Subway, World's Fair, St. Louis.

work and supervision. The two upper rows of brackets will be used for telephone, telegraph, and fire-alarm cables, whereas the other brackets carry the light and power cables. Unprotected bare lead cables are used throughout the whole installation, and in the three-phase lines the conductors are disposed in an equilateral triangle, and are twisted in order to prevent mutual induction.

FIG. 5.—Laying Cables in Wooden Ducts, World's Fair, St. Louis.

Where this subway crosses the lagoons it was not possible to build the subway, and the cables will, therefore, be installed in tile ducts. Figs. 3 and 4 represent this type of installation. The cross-section shows 60 of these tile ducts, each one having an interior diameter of 4in.; 10 of these ducts are put in one layer, making a total of six layers. All of these ducts are enclosed in a water-tight cement casing which rests upon a wooden support. In order to exclude any possibility of leakage, the prescription to the contractor was that the cement casing must be poured without interruption, thus necessitating day and night work. The wooden subway is 4,200ft. long, the total length of the cement casing with the 60 ducts is 540ft. The cost of the construction of these two subways amounted to £5,460. For all branches the cables are installed in wooden conduits (see Figs. 1 and 5), similar to those used for primitive water-mains.

Each of the principal buildings is provided with a transformer station, the whole output of the transformers amounting to 16,400 kw. The larger part of this electrical energy serves for light purposes, especially for the exterior illumination of the buildings. Power transformers are also provided in several buildings, and 1,900 kw. is available for this purpose. Rotary converters will be installed in all cases where direct current is needed, especially where arc lamps must be used, as these cannot be fed from an alternating line on account of the low frequency of 25 cycles per second. The primary wiring has no neutral, and the line is run at 6,600 volts. On the secondary side the neutral point of the transformer is used, and the lamp voltage is 110.

FIG. 6.—Installing the Decorative Illuminations, World's Fair, St Louis.

Special attention has been paid at the World's Fair to the exterior decorative illumination, and in the principal buildings alone the number of lamps provided for this purpose will be over 230,000. Besides this, 2,100 kw. is used for the illumination of the cascades; also a large amount for the illumination of the State buildings, buildings of the foreign Governments, and for the concessions. The 8-c p. incandescent decorative lamps are distributed upon the different buildings as follows: liberal arts' building, 20,000; educational building, 20,000; manufacturers' building, 30,000; palace of electricity, 20,000; varied industries building, 30,000; machinery hall, 30,000; transportation building, 30,000; horticulture building, 10,000; agricultural building, 20,000. The lamps are installed in such a manner as to follow the contours of the buildings, and are spaced from 10in. to 15in. apart. In the colonnades the lamps are installed on the back of the columns, so that the light is thrown upon the white walls of the building, by which a very diffused light is produced. So-called illuminating receptacles are used for these installations, that is to say, small porcelain receptacles without outdoor globes and with side connection screws; the distance between these screws corresponds to the distance

Digitized by Google

the wires are strung, so that the wires run directly through; the wire is scraped bare at the attachment screw and clamped under the screw, thus permitting very rapid installation.

The circuits of the decorative illumination are entirely independent from the other lighting circuits and power circuits, so that the possibility of disturbances is minimised to the utmost. Four or five feeders run from each transformer house in the different buildings to the distributing points, which are installed directly under the roof, and are therefore almost inaccessible; from these distributing points the lamps are fed in groups of 20. Fuse plugs are used as safety devices at the distributing switchboards, whereas at the transformer stations automatic cut-outs are inserted in the feeders, and in the primary, also, an automatic cut-out oil switch of the Westinghouse type is installed. Besides this, dimmers are inserted in the decorative lighting circuits by which the brilliancy of the lamps may be gradually increased from "0" to full candle-power.

In the buildings the heavy cables are installed upon glass insulators, which are fastened to wooden cross-arms by wooden pins. The smaller feed wires are fastened to cleats, which are also used on the outside of the walls. The whole installation was executed according to the national electrical code, which has been worked out by the mutual agreement of the insurance companies, the electrical firms, and also the fire underwriters. These rule differ in many essential points from the rules of the German Electrical Society, and are far less strict and elaborate. For instance, wooden moulding is allowed according to the American national code, and wood is generally regarded as an insulating material. It is further interesting to note that the electrical installations at the World's Fair, St. Louis, are executed under the constant supervision of an official of the fire insurance company through which the buildings are insured; it is therefore seen that the American electricians have not succeeded in obtaining the same recognition by the fire insurance companies as their German colleagues. The accompanying illustration (Fig. 6) shows the method of installing the lighting decorations.

RADIUM AND OTHER RADIOACTIVE SUBSTANCES WITH A CONSIDERATION OF PHOSPHORESCENT AND FLUORESCENT SUBSTANCES. THE PROPERTIES AND APPLICATIONS OF SELENIUM AND THE TREATMENT OF DISEASE BY THE ULTRA-VIOLET LIGHT.*

BY WILLIAM J. HAMMER.

(Concluded from page 444.)

THE TREATMENT OF DISEASE BY ULTRA-VIOLET RAYS.

Some professional matters detained the writer in Copenhagen last summer for several weeks, and during his stay in that city he had the privilege of visiting the Finsen Light Institute at Rosenvaengat, a suburb of Copenhagen, and was enabled to investigate the system for the treatment of disease by light inaugurated by Dr. Niels R. Finsen. In Figs. 31 and 32 are shown views of the operating-room at the Finsen Institute, where a large number of patients from various parts of Europe were undergoing treatment at the time of the writer's visit. Dr. Finsen has conducted very extensive and most painstaking researches into the bacteriacidal effects of light, and he has found the violent end of the spectrum to possess remarkable curative powers, and he has also found that by utilising the blue, violet, and ultra-violet rays of the spectrum, those loathsome diseases of tuberculosis of the skin and lupus, diseases which have baffled surgical skill heretofore, have been successfully combated. It has recently been stated that in New York City alone there annually 20,000 cases of tuberculosis, with 8,000 deaths; and there is probably no disease with which mankind is afflicted which compares in deadly character to tuberculosis. In affecting certain of the internal organs it is known as consumption, and appearing externally, attacking the skin and underlying tissues, it is known as lupus vulgaris. As a rule it appears in single patches, most frequently attacking the face, especially the nose, cheek, and mouth. It may, however, attack the extremities, or, in fact, any portion of the body, and even mucus membranes. Fortunately, lupus is rather rare in this country, although very common in Europe. Koch and others have fully demonstrated that tuberculosis is due to the presence of specific organisms named "tubercle bacillus," which have been found to be present in both the internal and cutaneous forms of the disease. Doubtless many present remember the "blue glass craze" which swept over the country in 1876, or thereabouts. I have with me here a copy of General A. J. Pleasonton's book entitled "Blue and Sunlights: Their Influence upon Life and Disease," which I picked up in a second-hand book store some years ago; and I would commend the examination of this book to all who are interested in this subject. General Pleasonton and his system were condemned to both abuse and ridicule. Dr. Finsen, however, says "The general was absolutely on the right track."

For a considerable time Finsen's work received little credence and no encouragement; but he persisted in his investigations, and the results secured by him finally bore fruit, and to-day the world rings with his praises. In all parts of the civilised world his work is being taken up, and institutes are being founded for the treatment of disease by light rays—particularly the ultra-violet light. In England

PROF. NIELS R. FINSEN.

the initiative was taken by Queen Alexandra, and in Russia by her sister, the Czarina, they both investigating the system while visiting their father, the King of Denmark. Much has also already been done in the United States. It will be remembered that during Queen Elizabeth's reign a certain Court physician recommended strongly that patients suffering from small-pox should be kept in a room, the decorations of which, including the hangings, bed draperies, etc., should be red in colour, claiming that the red light had a soothing effect upon the irritated portions of the skin, lessening the severity of the disease. Little importance was attached to this method, and the originator of it was branded as a charlatan. Prof. Finsen has, however, found that this method of treatment of small-pox is of paramount importance. He has placed patients in a room into which the sun's rays could only penetrate through sheets of red glass, just as they would penetrate a photographic dark room, and he has found that patients placed in such a room prior to the most painful and most dangerous suppuration stage setting in, that suppuration has been entirely prevented, and that the scarring has been in nearly all cases absolutely prevented, and in the few cases where there was any scarring it was hardly perceptible. The disease has been in a much milder form, the fever usually accompanying the eruption disappearing, and the temperature remaining normal.* He has found that the use of

* A lecture delivered at a meeting of the American Institute of Electrical Engineers and the American Electrochemical Society, New York, April 17, 1903.

* Prof. Finsen has recently written the author that placing the patients in a dark room is fully as efficacious as placing them in a room lighted with red rays only, the important thing being to keep the patient from exposure to the actinic rays.

Digitized by Google

ultra-violet light on these patients very much aggravated the disease, and even in cases where patients were almost cured, and they have been allowed to go out into the sunlight, the disease has at once been aggravated.

In connection with his investigations into the effects of light, Finsen made some interesting and ingenious experiments upon earth-worms placed in a box, one-half of which

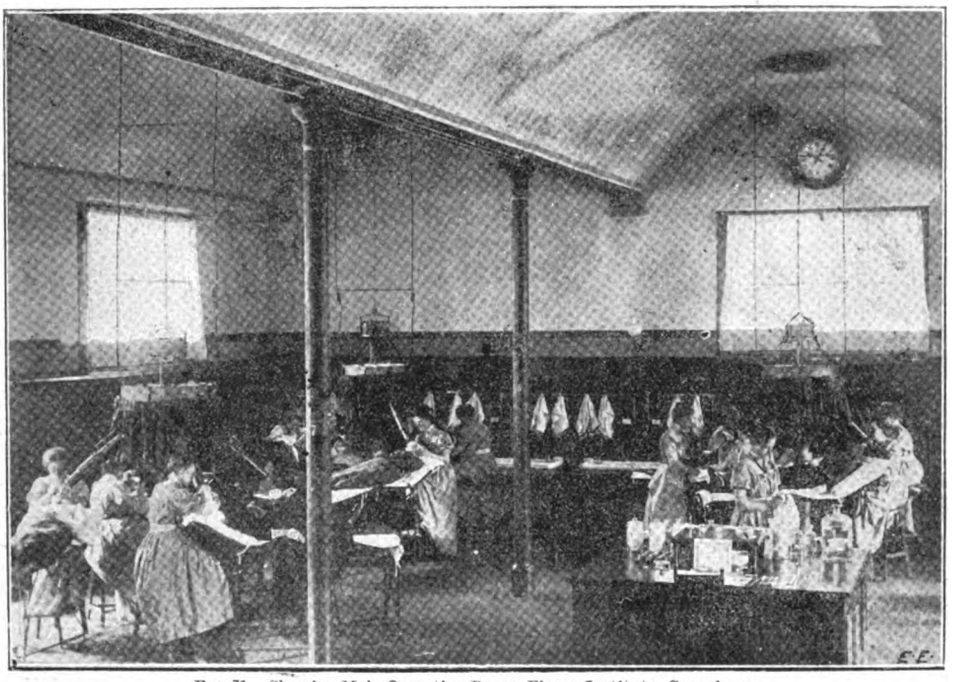

FIG. 31.—Showing Main Operating Room, Finsen Institute, Copenhagen.

was covered with red glass and the other half blue glass, and he found the blue light irritated the worms so they invariably crawled under the red glass; and a chameleon, placed with its body midway between the glasses, turned almost jet black under the influence of the blue rays, while that portion under the red glass remained nearly white, which Prof. Finsen says showed that the chameleon

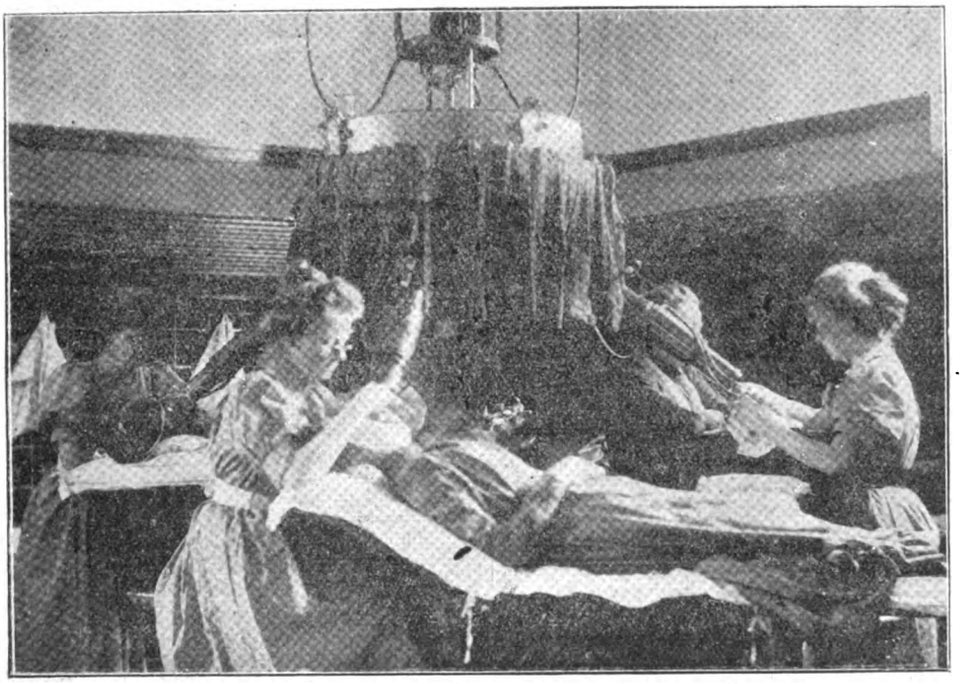

FIG. 32.—Showing Arc Lamp and Four Finsen Tubes in use at one time.

was altering its pigment cells to lessen the irritating effects of the blue light. The ultra-violet end of the spectrum contains the most refrangible rays, and it is these rays which are so harmful in cases of small-pox, and it is also these actinic rays which produce sun-burning, which one often experiences in the Alps or any high altitude where the temperature may be considerably below zero; and there are doubtless many present who have experienced considerable effect similar to sunburning by working in close proximity to arc lamps. While these ultra-violet rays are so harmful in the case of small-pox, they are of the precise nature which is most desirable in the treatment of such diseases as tuberculosis of the skin or lupus vulgaris. These rays not only destroy the bacilli, but they excite and stimulate nutrition and excite activity in granulation, thus assisting very greatly in the rapid recovery from the disease. Doubtless the rays emanating from the sun are very rich in blue, violet, and ultra-violet light, but the atmosphere readily absorbs these rays; and while Prof. Finsen for a time used the sun's rays in the treatment of tuberculosis of the skin and lupus, he found that by employing the arc light the same effect could be produced in a very much shorter space of time, and that he was in this way also independent of weather conditions.

The arc light is much richer in ultra-violet rays than the sunlight, and Broca and Chatin, of Paris, have found that by placing an iron core inside of the positive carbon electrode, this arc was still richer in ultra-violet light, and Görl, of Erlangen, has constructed a form of aluminium

Digitized by Google

arc in which four arcs were formed between five aluminium electrodes. I have here a modification of Görl's lamps constructed by Messrs. Waite and Bartlett, of this city, in which there are four iron electrodes forming three iron arcs in series, which produce an intense source of ultra-violet light, which I shall presently show in operation. Bang and others have also made arc lamps employing

FIG. 32A.—Dressing Room, Finsen Institute, Copenhagen.

terminals of iron. It is claimed that by employing the iron arc the same results which take an hour and 10 minutes by means of the carbon arc can be accomplished in 20 minutes to half an hour, and also that so intense are these ultra-violet rays it is not necessary to use pressure to drive the blood away from the diseased part, and it is also unnecessary to use water to cool the rays.* Drs. Piffard and Jamieson have suggested the use of suprarenal extract in the form of adrenalin chloride, which the former prefers to introduce into the skin around the diseased spot by cataphorisis, thus producing a whitened area from which

FIG. 33.—Lupus Vulgaris, cured by X-Rays.

the blood has been withdrawn, which enables the treatment of this portion by the ultra-violet light without pressure being applied, and the blood does not return for half an hour or more. The cataphoric electrode is covered with a thickness of lentine saturated with adrenalin connected with a positive pole of the battery, using a current of from three to four milliamperes, the bleaching taking from four to five minutes' time.

The Röntgen rays have been found very effective in the treatment of certain diseases, especially where hard tubes are employed, and as we are considering particularly the treatment of lupus vulgaris, I would call attention to Fig. 33, which represents a patient treated by my friend, Dr. William H. King, of this city, in which the X-rays successfully cured a case of lupus vulgaris brought on by the patient's pricking a tiny boil on the side of his nose with a pin taken from the lapel of the coat of a friend who was suffering from tuberculosis (consumption). The rapid progress of the disease is shown in the illustration, and was taken three weeks after using the pin, and was largely augmented by the man's age (45), and his being in poor health (a chronic rheumatic). Two bacteriological exami-

FIG. 34.—Finsen's Original Blue Lens for use with Sunlight.

nations showed conclusive evidence of the presence of tubercle bacilli. In Fig. 34 is shown the original blue lens used by Finsen when employing sunlight. It consists of a flask full of light-blue ammoniacal sulphate of copper. The bottle with its contents makes a plano-convex lens. The sunlight passing through

* Prof. Finsen has recently written the author emphatically asserting that iron electrodes are not as efficacious as carbon electrodes, as the rays from the iron arc, he claims, do not penetrate as deeply as the rays from the carbon arc.

Digitized by Google

this is found to work very well; but it was too slow, and the sun was frequently obscured. Finsen later used plain water, finding that the blue water cut off most of the ultra-violet rays, and he found the clear water very largely absorbed the ultra-red rays which caused the heat.

In Fig. 35 is shown a form of telescope which is now adapted in standard practice at the Finsen Institute. It contains four rock crystal lenses, which act to cut off considerable of the heat rays, but allows the ultra-violet light to pass through it. It will be remembered that ordinary glass cuts off almost all of the ultra-violet rays, whereas a

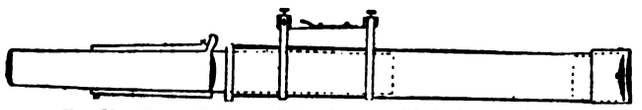

FIG. 35.—Finsen Telescope Tube, for use with Carbon Arc Light.

block of rock crystal 4·4mm. thick will allow 60 per cent. of the ultra-violet to pass through it. A part of the heat is also absorbed by the distilled water which is contained inside of the telescope. In order to keep this water cool, there is an outside jacket on the telescope, through which circulating water may be passed for this purpose. In Fig. 36 is shown the method of arrangement of the telescope and the arc lamp; and in Fig. 32 is shown a set of four of these telescopes arranged around the arc lamp and in actual operation. The arc lamp uses from 40 to 80 amperes and

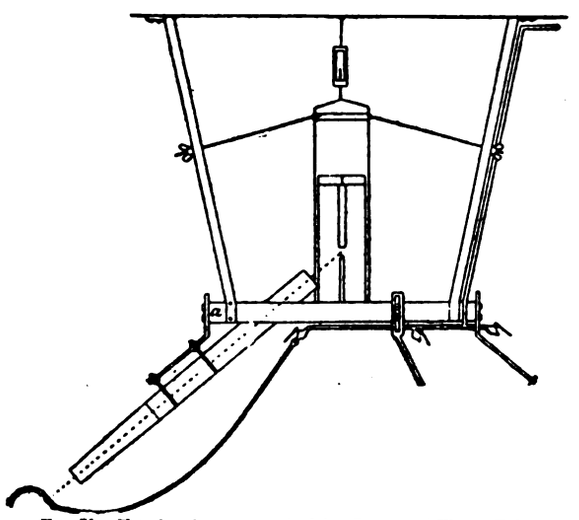

FIG. 36.—Showing Arrangement of Arc Lamp and Finsen Tubes.

operates at 45 to 50 volts. Blood is opaque to ultra-violet light, and it is therefore necessary to drive the blood away from the diseased portion which is to be treated. This is accomplished by what is known as a pressure glass (shown in Fig. 37). It consists of a plano-convex lens of rock crystal kept cool by circulating water—the glass acting to focus the light on the diseased portion, and also to exert considerable pressure there. The patient does not suffer from exposure to the rays; but after the treatment, which is usually an hour and 10 minutes per day, he appears

FIG. 37.—Pressure Lens.

to be considerably sunburned. He is then allowed to recuperate until the next day, and the treatment is then repeated. After a series of these treatments, the patient is sent away apparently cured. Sometimes he does not return, but more often he must come back for a second or a third, and even more series of treatments, due to the fact that certain of the microbes which have been deep seated have worked their way to the surface, the disease having started anew.

It is said that out of over 600 cases treated at Copenhagen, there have been only 1 to 2 per cent. of failures due to fault in the treatment, but there have been cases where the disease has been in such an advanced stage and for such a very long period that it has not yielded successfully. But I was informed that in the majority of cases after very few treatments, the patients are dismissed absolutely cured. In order that you may properly appreciate the remarkable results which have been secured by Prof. Finsen, and the stupendous importance which his successful combating of these loathsome forms of disease represents to many of the most sorely afflicted people of the world, I have inserted in my paper several photographs (see Fig. 38), which I secured at the Finsen Institute, of patients afflicted with lupus vulgaris—these pictures showing them before and after the treatment with the ultra-violet rays produced by the arc light. I feel that their presentation in this paper requires no apology; on the contrary, electrical engineers should feel a sense of pride that in the use of the arc light in this remarkable advance in medicine and surgery, their profession has contributed in no small degree. Those caring to look up these and similar cases will find full descriptions in English in "Phototherapy after Finsen's Methods," by Valdemar Bie, M.D., Prof. Finsen's assistant (published by Lippincott), or "Die Bekampfung des Lupus Vulgaris Niels R. Finsen" (Gustav Fischer, Jena), and "Die Finsen von Therapie und ihr gegenwartigen stand in des Dermatologie" (Von Dr. Forch-hammer, 1 Cohen's Buchdruckereien, Kopenhagen). It is sad to contemplate that Prof. Finsen, who has conferred such a priceless boon upon humanity, is

FIG. 38.—Showing a Patient of Lupus Vulgaris Before and After Treatment with Ultra-Violet Light at the Finsen Institute, Copenhagen.

himself an invalid, suffering from an incurable disease, and one which has made it at times well nigh impossible for him to prosecute his work. The Finsen Institute was established in 1896, through the munificence of Copenhagen's public-spirited citizens, and through a gift by the city of the property on which it was erected.

THE PARALLEL WORKING OF ALTERNATORS.*

BY B. HOPKINSON.

The question of the parallel working of alternating-current dynamos, under which term may be included the working of synchronous motors and of rotary converters, has been much discussed during the 20 years which have elapsed since it was first shown that it could be done. No very definite result, however, has been arrived at from the theoretical point of view, though engineers have evolved various empirical rules of design, and have produced the well-known "amortisseurs," in consequence of which the difficulties of parallel running have ceased to be serious, and the theoretical problem has lost much of its importance. Of late, however, a new interest has been given to the discussion of this question by the introduction of large gas-engines, with which it is more difficult than with steam to satisfy the requirements of the dynamo designers as to the uniformity of angular velocity necessary for satisfactory running. In this paper I do not propose to add much new matter to the discussion, but rather to attempt to co-ordinate the

* Paper read at the British Association, Southport, 1903.

Digitized by Google

mathematical treatment of the subject with the practical rules which have been framed, and which are now regarded as good standard practice, and to point out the reason for certain phenomena which have been observed. It would appear that hitherto the mathematical treatment of the subject has been carried out without sufficient reference to practical conditions, and on the other hand it is possible that the empirical rules of practical engineers, though their success is a sufficient guarantee of their correctness under the conditions to which they have been applied, may not be fully applicable without modification to the new conditions which have followed the introduction of the new types of prime mover.

Dynamically, the question of the parallel working of alternators, or the running of a synchronous motor or converter, is a problem of oscillation about a state of steady motion. Consider an alternating dynamo connected to a source of supply of constant amplitude and periodicity, and driven by a constant power or working against a constant resistance. For simplicity of expression we may suppose that the dynamo, and the generators giving the supply, have all the same number of poles. Then the dynamo will run with the same angular velocity as the supply generators, but with a certain difference of phase, which we may call ϵ, dependent on its excitation and on its load or driving power. This is the state of steady motion. If that state be disturbed—say, by temporarily varying the load on the dynamo if working as a motor—the dynamo will make oscillations about it, sometimes running ahead of and sometimes lagging behind the position of steady motion. When ahead of that position it will take less, and when behind it will take more, than its proper supply of energy from the mains. The practical problem is to keep these oscillations, with their accompanying fluctuations in the flow of energy to or from the mains or 'bus bars, within moderate limits.

The oscillations may be either free or forced. To clear the ideas we may consider the case of a dynamo working as a synchronous motor, but the results are immediately applicable to the case of a generator. Suppose that the load on the motor is slightly increased. The motor will take up a position in which the phase difference between it and the generators is rather greater than before, becoming say, $\epsilon - \xi$, where ξ is reckoned positive in the direction of motion of the motor. The torque developed by the motor, which was T, is now $T - \xi \frac{d\,T}{d\,\epsilon}$, or, say, $T - c\,\xi$. The constant c is readily calculable from the electrical constants of the machine. If, now, the additional bit of load $-c\,\xi$ be removed, there will be a balance of torque of that amount available for accelerating the motor, which, accordingly, will proceed to catch up, so to speak, the state of steady motion. After a time it will arrive at the position of steady motion, corresponding to torque T (for which, of course $\xi = 0$), but will then be moving with more than the steady motion velocity. In consequence of the difference of velocity, the motor will not exert quite the steady motion torque, T, but there will be a balance of torque tending to accelerate it or retard it. This, if the difference in velocity is small, will be proportional to that difference and equal, say, to $b \frac{d\,\xi}{d\,t}$. Adding the effect of this and of the term $c\,\xi$, we find the equation of motion of the motor,

$$M \frac{d^2\,\xi}{d\,t^2} + b \frac{d\,\xi}{d\,t} + c\,\xi = 0,$$

where M represents on a suitable scale its moment of inertia. Under a rigorous mathematical treatment, differential coefficients of higher order will appear, but the terms here given are the most important. The solution of this differential equation is

$$\xi = \xi_0\, e^{-\frac{b}{2M}t} \sin(\delta\, t + \eta),$$

where $\frac{2\,\pi}{\delta}$ is the period of the oscillation and δ is equal to $\sqrt{\frac{c}{M}}$ nearly, if (as is usually the case) b^2 is small compared with $4\,c\,M$.

The oscillations represented by this expression are the free oscillations executed by the dynamo when disturbed by a temporary change of conditions—*e.g.*, if its load be suddenly thrown off, or if, being a generator, it be switched into parallel with its fellows. Dr. Hopkinson showed many years ago that the quantity c is positive—in other words, that if the state of steady motion be disturbed the forces so called into being tend to restore it, or the motion is stable. Since then Kapp and others have worked out the value of c. It is easy to show that, sufficiently nearly for all practical purposes,

$$c = \sqrt{\frac{A^2}{2\,L'}}$$

where $\frac{A\,p}{\sqrt{2}}$ is the open circuit E.M.F. of the dynamo ($\sqrt{\text{mean}^2}$) ($2\,\pi/p$ being the periodic time of the alternations) and L the self-induction of the armature, including therein the armature reaction and the self-induction of any conductors in series with the armature. Another expression for c, at once deducible from the above, is $c = \sqrt{\frac{E\,i_0}{p}}$, E being the open circuit E.M.F. and i_0 the current in the machine when short-circuited and driven at the proper speed.

It is obvious that the importance or otherwise of these free oscillations depends on whether they are damped out or not. It has usually been assumed that b is a positive quantity—*i.e.*, that the oscillations are resisted by a sort of viscous force—and if that is so the oscillations will, of course, rapidly disappear. I have, however, recently shown that under certain circumstances b may be negative, in which case the oscillations will continually increase in amplitude and the running of the dynamo will be unstable, even though b be very small.

Suppose that the dynamo is working as a generator and is driven by a force with a certain periodic variation—*e.g.*, by a reciprocating engine. It is supposed to be coupled in parallel with such a number of other machines that the 'bus bar potential is practically constant. The equation of motion then is

$$M \frac{d^2\,\xi}{d\,t^2} + b \frac{d\,\xi}{d\,t} + c\,\xi = P \sin \delta'\, t,$$

where $2\,\pi/\delta'$ is the period of the variation in the force. The solution of this equation is (leaving out the free oscillations)

$$\xi = \frac{P}{\sqrt{b^2\,\delta'^2 + (c - M\,\delta'^2)^2}} \sin(\delta'\, t - \eta),$$

where

$$\tan \eta = \frac{b\,\delta}{c - M\,\delta'^2}.$$

I shall presently show that in practical cases $b\,\delta'$ is small compared to c, so that the equation for ξ is, unless c is nearly equal to $M\,\delta'^2$,

$$\xi = \frac{P}{c - M\,\delta'^2} \sin \delta'\, t,$$

$$= \frac{P}{c\left(1 - \frac{\delta'^2}{\delta^2}\right)} \sin \delta'\, t,$$

where $2\,\pi/\delta$ represents, as before, the period of the free oscillations. These are the forced oscillations produced by uneven turning moment in the prime mover. Superposed on them there will be the free oscillations already considered.

The possibility of parallel working, or of the working of a synchronous motor, therefore depends on two conditions. First, the quantity b must be positive, so that any free oscillations are damped out within a short time of being set up. Second, the forced oscillations must be of such moderate amplitude as not to interfere with practical working. I will deal first with the last-named condition, as it admits of much simpler treatment than the other.

For an ideal machine, without any flywheel effect at all, δ is infinite, and we have $\xi = \frac{P}{c} \sin \delta'\, t$. In this case the

Digitized by Google

phase displacement is always such as to correspond exactly with the torque exerted by the prime mover. Such a machine would run fairly well in parallel with others, simply delivering to the 'bus bars at all times exactly the energy given to it by its engine. But, now, if a flywheel be added, δ becomes finite, and so long as it remains greater than δ'—that is, so long as the natural period of the alternator is less than that of the variation in turning moment—the amplitude of the oscillations becomes greater with increase of flywheel until, when $\delta = \delta'$, there is perfect resonance, and the oscillations are only restrained by the viscous damping. Further increase in the flywheel effect results in a continuous diminution of the oscillations. If δ is so far diminished by increasing the flywheel that δ' is several times as large as δ, the formula for ξ becomes

$$\xi = -\frac{\frac{P}{c\,\delta'^2}}{\delta^2} \sin \delta' t$$

$$= -\frac{P}{M\,\delta'^2} \sin \delta' t.$$

Now, the practical rule always adopted by designers for working in parallel is that the angular displacement of the machine in a revolution when running unloaded as compared with a uniformly revolving wheel shall not exceed a certain fraction (varying from $\frac{1}{110}$ to $\frac{1}{70}$) of the angular pitch of the poles. If the machine is unloaded the equation of motion is

$$M \frac{d^2 \xi}{d t^2} = P \sin \delta' t,$$

or,

$$\xi = -\frac{P}{M\,\delta'^2} \sin \delta' t.$$

ξ is the phase-angle of displacement measured in such units that the angle between a pair of adjacent poles (or pitch-angle) is π. The practical rule, therefore, directly limits the angular amount of the forced oscillations, provided that δ' is large compared with δ, or that the natural period of oscillation of the alternator is large compared with the period of variation in turning moment.

Limitation of the angle by which the machine deviates from perfectly uniform rotation is not, however, precisely what is needed. What should be limited is rather the amount of the fluctuation in the rate at which energy is delivered by the machine to the 'bus bars. This, since the speed is practically constant, is proportional to the variation of torque—that is, to $c\,\xi$. Now, c is equal to $\sqrt{\frac{A^2}{2L}}$, and depends upon the electrical properties of the machine. Hence a machine with small self-induction will operate worse in parallel under a given amount of angular displacement than will another of large self-induction, always supposing the above-mentioned condition of long natural period to be fulfilled. Here, therefore, is a sufficient explanation of the wide variation in angular deviation permitted by different designers; what suits one machine will not suit another, and a machine with small self-induction and armature reaction, or what is called a machine with good inherent regulation, must be subject to more stringent rules as regards angular deviation than one with large self-induction.

Another cause which makes a fixed rule as to angular deviation inapplicable to all cases, is the fact that in some designs the natural period of oscillation may not be long, compared with the period of the engine impulses. Should these two periods become even approximately equal—if, for example, δ were anywhere within 20 per cent. of δ' then the rule quite ceases to be applicable, and the amount of angular deviation in actual working as a generator bears no fixed relation to, but is much greater than, the same deviation when unloaded. As a matter of fact, in machines as now designed, in which the self-induction and armature reaction are usually sufficient to allow the machine to be short-circuited when partially excited without damage, the natural period of oscillation even without a flywheel is usually greater than the period of engine impulse. The latter period, even in a slow-speed engine, will not, as a rule, exceed one-third of a second, while the natural period will be found to be of the order of half a second or more, and very much greater with a heavy flywheel. Probably, therefore, a designer will generally be justified in assuming that the two periods are sufficiently different to ensure that he will get about the same angular deviation when delivering energy to the 'bus bars as when the machine is running disconnected. He will, however, have to take account of the change in the rate of flow of energy to which that deviation corresponds on his particular machine, and it is in neglecting that factor that the practical rule seems to be illogical.

We have, so far, considered that particular component of variation in turning moment which is responsible for the major part of the phase displacement when the machine is running disconnected, and which is, accordingly, alone regarded in the practical rule for flywheel effect. That, however, is not in fact the only component of the variations; there will be other components of both longer and shorter period. Take, for example, the case of a single-cylinder double-acting Körting gas-engine running at 90 revolutions. The principal variation in turning moment, and the only one producing any appreciable effect on the phase displacement when running light, will be due to the explosions, and will have a period of one-third of a second. As stated above, the natural period of oscillation of the alternator will probably be much greater than this. But there will also be a variation in turning moment due to the weight of the crank, with a period the same as that of the revolution of the engine, or two-thirds of a second. Now it is not impossible, with a light flywheel, for the period of oscillation of the alternator to have that value, and if that were so violent hunting would be set up, even though the variation in turning moment due to this cause were too small to produce an appreciable effect on the phase displacement when running light. Only, in this case of a small disturbing force, the approximation of periods must be fairly close to produce serious effects. The ordinary rules as to flywheel effect generally result in the natural period of oscillation being substantially greater than the period of revolution of the engine, but in a somewhat roundabout and accidental way. It seems highly desirable on many grounds to pay more attention than has hitherto been usual to the natural period of oscillation of the alternator when specifying flywheels. The period of oscillation of the governor of the engine should not be lost sight of. This is generally fairly long, and may not impossibly give rise to resonant oscillations.

So far, we have considered the forced oscillations caused by the uneven turning moment of the prime mover in a generator working in parallel with a number of others. A very similar and equally important problem is that of a synchronous motor or rotary driven from mains in which the potential varies periodically owing to unevenness of rotation in the supply generators. Here, if the motor or rotary had no flywheel effect at all, it would follow the generators precisely in their oscillations, and it is easy to see that if ξ_0 be the maximum phase displacement in the generators and ξ_0' that in the rotary, then

$$\xi_0' = \xi_0 \Big/ \left(1 - \frac{\delta'^2}{\delta^2}\right),$$

where $2\pi/\delta'$ is the period of the variation in the generators, and $2\pi/\delta$ the natural period of oscillation of the rotary. In the case of a rotary, however, it is unusual to have any flywheel, and consequently δ, though usually less than δ', may be sufficiently near it to cause the oscillations of the rotary to exceed in amplitude those of the generator. Furthermore, the danger of actual resonance with the revolution of the engine, is in this case very much greater. I came across a case recently of a motor-generator which could not be worked owing to resonance. Its natural period happened to be very nearly equal to that of the revolution of the generator—about two-thirds of a second—and it dropped out of step in a very short time, though the variation of turning moment of the period in question must have been quite small. By altering the field current so as to increase the natural period about 25 per cent., the forced oscillations disappeared almost completely, showing that the difficulty was entirely due to resonance. This suggests the reflection that it might possibly be better in some cases to put flywheels on the comparatively high-

Digitized by Google

speed rotaries, and allow a small flywheel and a bigger angular deviation in the slow-speed generators.

The question of free oscillations is a very much more complicated and difficult one than that of forced oscillations. The period is, of course, easily determined, but, as already indicated, the importance or otherwise of these oscillations depends almost entirely on the way in which they are damped or on the sign of the quantity b. If b be positive, the oscillations are damped out and are unimportant. On the other hand, if b be negative, even though very small, the oscillations will continually increase according to an exponential law, and the running of the machine will be impossible as a practical thing. The stability or otherwise therefore depends in this case on the sign of a small quantity and may be affected by a very small change in the conditions. I have recently investigated this question, and I have shown that under certain circumstances* b may be negative. I will not reproduce the mathematics here, but will merely give the conclusions.

Consider an ideal synchronous motor in which the exciting current is maintained absolutely constant, while the field magnets and the armature core and conductors are so perfectly laminated that no appreciable eddy currents flow therein. I find that the motion of such a motor is unstable or b is negative, provided that $\mathrm{L}\,p > \rho$ Here ρ is the resistance and $\mathrm{L}\,p$ is the reactance of the armature and any conductors in series with it. The actual value of b I find to be

$$-\frac{1}{2}\rho\,\mathrm{A}^2\,\frac{\mathrm{L}^2\,p^2-\rho^2}{(\mathrm{L}^2\,p^2+\rho^2)^2}.$$

The condition $\mathrm{L}\,p > \rho$ is generally fulfilled, so that an ideal motor such as that described is in general unstable, and all motors have this element of instability. In actual machines, however, there are a number of causes which give rise to real viscous forces, and generally overcome this tendency to instability. Such are the local currents induced in the substance of the armature conductors, and (generally but not always) the "amortisseur" effect of currents induced by the oscillations in the pole-pieces, the field coils, and in any special "amortisseur" coils put there for the purpose. It will be found, on working out the value of b, that in machines of modern design and any considerable size, it is insignificant under ordinary conditions of working. In small machines, however, and in large ones on long transmission lines, it may be important. I have myself experimented with a small motor, the running of which was actnally unstable from this cause.

Of the causes mentioned above as making for stability by producing a viscous damping effect, the most important is that described as giving rise to "amortisseur" action. Consider an ideal motor of the type described in the last paragraph coupled to mains giving constant alternating potential moving steadily and doing external work. For simplicity, we may suppose the open-circuit potential of the motor to be equal to that of the mains. The effect of the armature current on the field will be to decrease the induction in the field magnets somewhat and also to distort it, so that the point of maximum induction and zero back E.M.F. is displaced backward against the direction of rotation. Suppose, now, that the motor executes oscillations about the position of steady motion. Then the field will experience variations of like period, both as regards its magnitude and its distortion. To put the matter in symbols, suppose that $\mathrm{A}\cos\theta$ is the induction linked with armature and field coils in the steady motion (θ being an angle defining the position of the armature). Then in the oscillation which is given by $\xi = \xi_0 \sin \delta\, t$, the induction will be $(\mathrm{A} + a_0' \sin \delta\, t) \cos\theta + b_0' \sin \delta\, t \sin\theta$, the quantities a_0' and b_0' being positive, since when ξ is positive there is a greater total induction and a less displacement of point of maximum induction than when ξ is zero.

Now suppose that the pole-pieces are surrounded by short-circuited copper conductors, and that the pole-faces are covered with copper plates, or have copper conductors threaded through them to form a grid. Then the changes of magnetising force due to the armature current will cause induced currents to flow in these conductors, and the general effect of the currents will be to somewhat reduce the amplitude of the changes of induction in the pole-pieces, and to cause them to lag rather behind the changes in armature reaction which give rise to them. The consequence is that the induction linked with armature and field coils is now

$$\{\mathrm{A} + a_0 \sin('t - \eta)\} \cos\theta + b_0 \sin(\delta\, t - \zeta) \sin\theta,$$

where a_0 b_0 are (for the motor) positive quantities less than a_0' and b_0' respectively, and η ζ are positive angles which depend upon the resistance of the "amortisseur" conductors and on the armature reaction. Thus, at the time when the armature is passing the position of steady motion ($\xi = 0$), but moving with more than the steady motion velocity, the induction, instead of having its normal value, $\mathrm{A}\cos\theta$, has the value $(\mathrm{A} - a_0 \sin\eta)\cos\theta - b_0 \sin\zeta \sin\theta$. In other words, the currents then circulating in the "amortisseur" coils are such as to reduce the magnetisation somewhat, and to displace the point of maximum induction or zero open-circuit E.M.F., rather behind the position which it would occupy in ordinary steady motion. We have now to consider the effect of these changes in the induction on the torque at this moment, since it is the then deviation of the torque from its steady value that determines the value of b.

First, as regards the demagnetisation, due to diminution of current in the field coils, or to currents in short-circuited windings surrounding the pole-pieces. It is easy to show that the effect of reducing the field current in a synchronous motor may be either to increase or diminish the torque—it depends on the load on the motor. Let β_0 be that component of the current which is in phase with the back E.M.F., and $\mathrm{A}\,p$ the back E.M.F. of the motor, so that the rate of working of the motor is $\frac{1}{2}\,\mathrm{A}\,p\,\beta_0$. Then a reduction in the field current will result in a reduced torque provided that

$$\beta_0 > \frac{\mathrm{A}\,p\,\rho}{\mathrm{L}^2\,p^2+\rho^2},$$

where, as before, ρ is the resistance, and $\mathrm{L}\,p$ the reactance of the armature and any conductors in series with it. Similar considerations apply when the dynamo is working as a generator, only in this case the effect of the induced currents when $\xi = 0$ is to increase the magnetisation while the sign of β_0 is changed. The general result is that if β_0 be outside the limits $\pm\frac{\mathrm{A}\,p\,\rho}{\mathrm{L}^2\,p^2+\rho^2}$ the induced currents tend to damp out the oscillations. On the other hand, if β_0 be within these limits, the induced currents tend to increase the oscillations, and under such circumstances damping coils surrounding the pole-pieces are additional causes of instability. In the case of a machine connected direct to 'bus bars in parallel with others, these limits for β_0 are very narrow; but in motors or converters on long transmission lines they may be so far apart as to give rise to instability at light loads. There is little doubt that trouble has been experienced from this cause. It was one reason for the instability of the small motor to which I have referred, and the constants of that motor might easily be repeated on a much larger machine if there were considerable self-induction and resistance in circuit with it.

We may now consider shortly the damping effect of solid pole-pieces, copper plates over the pole-faces, or copper bars threaded through the pole-face to form a grid. As already pointed out, the effect of the currents in such conducting bodies at the moment when the motor is in the position of steady motion, but moving with more than the steady motion velocity, is to so distort the field as to move the position of maximum induction somewhat behind that which it occupies in steady motion. This is in effect the same as reducing the phase difference between motor and generators, and it therefore in all cases results in a reduction of the torque of the motor as compared with the normal steady motion torque, or on the balance in retardation of the motor. Hence damping coils of this kind invariably exert a true damping or viscous effect. Moreover, I have worked out the amount of the effect, and find that it is much greater than that due to the variation of current round the pole-pieces. It is these conductors across the face of the pole-pieces that are the really useful

* Paper read before the Royal Society, June 18, 1903.

Digitized by Google

"amortisseurs," and by their use it would seem that b can always be made positive and the motion stable.

I do not propose here to go into the actual value of the damping effect produced by these "amortisseur" coils. It has been worked out, and the results will shortly be published. One thing, however, may be noted here, and that is that as the resistance of the coils is diminished, the effect increases to a maximum and then diminishes. It is obvious that if the pole-pieces were surrounded by perfectly conducting coils and faced with perfectly conducting plates, there could be no changes of induction produced by an oscillation about steady motion, and, therefore, no damping effect. The point is that the coils diminish the amplitude of the changes of induction produced by armature reaction approximately in proportion to their conductivity, and at the same time give rise to a difference of phase between those changes and their cause. The amount of damping effect is proportional to the amplitude of the changes and to the phase difference. It is, therefore, possible to increase the conductivity of the coils too far—that is, to such an extent that the diminished amplitude more than compensates the increased phase difference. Whether this happens in practice I am not prepared to say, as it depends on many elements, such as the period of oscillation, amount of armature reaction, etc., but I am clear that it is not impossible with constants such as one meets with in ordinary designs.

One other point is of interest in connection with "amortisseur" coils. They have been regarded here as a means of making b positive, or of removing that tendency to instability as regards free oscillations which is inherent in all machines. Of their great value for that purpose there can be no doubt whatever. It has often been suggested that they also play an important part in reducing the forced oscillations which were considered in the first section of this paper. My own belief, however, is that their action in that respect is insignificant. Looking back for a moment to the expression for forced oscillations, damping being taken into account, we found that it was

$$\xi = \frac{P}{\sqrt{b^2 \delta'^2 + (c - M \delta'^2)^2}} \sin (\delta' t - \eta),$$

while the free oscillations were

$$\xi = \xi_0 e^{-\frac{b t}{2M}} \sin (\delta t + \epsilon).$$

Now, by the courtesy of the Westinghouse Company I have been able to observe the free oscillations on a rotary converter fitted with heavy dampers round the poles and across their faces. The design of these coils was the outcome of much experience, and they may probably be taken as giving the most powerful attainable damping effect. I found that if the machine were paralleled when a little out of phase, one could hear it make six or eight complete oscillations There can be no doubt that the ratio of the two successive oscillations was much less than $1/e$. Assuming it to be equal to $1/e$, we readily find that

$$\frac{b}{2M} \cdot \frac{2\pi}{\delta} = 1.$$

Hence in the expression for the forced oscillation

$$b \delta' = \frac{\delta \cdot \delta' M}{\pi}.$$

Now I have already pointed out that the effect of the ordinary flywheel rules is to make δ considerably less than δ'. Hence $b^2 \delta'^2$ is but a very small fraction of $M^2 \delta'^4$, and unless c is nearly equal to $M \delta'^2$—that is, unless there be resonance—the forced oscillations are almost unaffected by the damping. If there be resonance we have $\delta' = \delta$, and

$$b \delta' = \frac{M \delta^2}{\pi} = \frac{c}{\pi}.$$

Hence the amplitude of the forced oscillations is

$$\xi = \frac{P}{b \delta} = \frac{P \pi}{c}.$$

In other words, in case of resonance the forced oscillations would be about three times as big with this amount of damping as they would if there were no flywheel effect at all and no damping. It would seem, therefore, that damping coils are not of much use for dealing with cases of resonance. A slight variation of the period is a much better solution. To sum the whole matter up, the proper way to deal with forced oscillations is to use the right flywheel, while damping coils must be used for giving stable free oscillations.

MECHANICAL COAL-CUTTING.

A committee appointed by the North of England Institute of Mining and Mechanical Engineers to investigate the question of mechanical coal-cutting has just issued the first part of its report, which deals exclusively with long-wall machines. The full report should be in the hands of every consulting and contracting engineer having to do with coal-mining. The committee collected information in the first instance from some 80 colliery companies owning some 200 machines, and an analysis of the information gathered shows that (1) disc machines in long-wall faces are those most generally in use at the present time; (2) few collieries have been using them for more than six years, or to any large extent; (3) compressed-air machines are still in a large majority, although electricity is being increasingly used as the motive power—according to the reports of H.M. inspectors of mines for 1900, out of a total of 316 machines which were at work, electricity was the motive power in 69 only, but according to more recent returns the proportion now is about two driven by air to one by electricity; (4) the thickness of seams in which long-wall machines are in operation varies from 1ft. 1in. to 6ft. 6in.; (5) the depth of cut runs from 2ft. 10in. to 7ft.; (6) the amount of coal cut per machine per year averages roughly 13,000 tons. According to the reports of H.M. inspectors of mines, mentioned above, the average was about 10,000 tons. These figures correspond with those from America, where during the years 1890 to 1896 the tons per machine averaged a little over 10,000 tons, and rose to a little over 12,000 during the years 1896 to 1900; but the American machines are nearly all of the percussive and chain-breast types, and are working, as a rule, much thicker seams and under different conditions.

The committee afterwards made a selection of collieries to be visited in different localities, and 30 chosen for their representative character were inspected by the members. The three points chiefly investigated were cost of working as compared with hand labour, increased production per man employed, and increased percentage of round coal obtained using machines. Under the first heading the committee found that the cost of working per ton as compared with hand labour is reduced in some cases as much as 1s. But on the average from 4d. to 6d. per ton is saved, and in certain cases this cost is not reduced at all. On the other hand, on the average some 65 per cent. more coal is produced per man employed, and this is a very great advantage when house accommodation and free coal are given to the miners. It also enables scarcity of labour to be partially overcome, and may result in the working of thin seams of coal which could not otherwise be profitably undertaken. The increase of round coal varies from 5 to 20 per cent.—that is, 20 per cent. of the total output. In other words, if there is 60 per cent. of round coal worked by hand and 70 per cent. worked by machine, the increase is a 10 per cent. one. The report then discusses the conditions of working and the advantages of various types of machines to meet these conditions most economically. It shows that there is a great advantage in having a machine which will cut in either direction whenever practicable, as this saves a great loss of time in moving the machine from the one end of the face to the other. Into the details of the various makes of machines seen at work we do not propose to enter. As mentioned above, the majority in use at present are of the disc type, and the committee attribute to defective construction the comparative slow progress made by the bar machines. The chain machines introduced comparatively recently are stated to be gaining ground. They have most of the

Digitized by Google

advantages of the bar type, with the additional one that the chain brings out the cuttings better than the bar. The need for convenience for rapidly replacing the cutters is dwelt upon in view of the frequent changes required when working. The point in which our readers have the greatest interest is that of the motive power. At present electricity and compressed air are fighting for the supremacy. We, therefore, give the following extracts from the report on this point in full:

"The relative advantages and disadvantages of the use of compressed air and electricity for the purpose of transmitting power underground have been so often and so fully described and discussed, that it is not necessary for the purposes of this report to touch upon them any further than is requisite having regard to the coal-cutting machine itself. Until comparatively recently, compressed air has been more largely used in collieries for power purposes than electricity, and is still preferred by many engineers, despite its lower efficiency, more especially in mines which are of a fiery nature and subject to outbursts of gas, on account of its greater safety under such conditions. The great improvements in air-compressing plant, by means of which the output has been greatly increased and the supply of air regulated in accordance with the demand, as well as the advance which has been made in the manufacture of cheaper and better pipes for its conveyance, have materially increased the efficiency of compressed air. Its comparative simplicity, when placed in the hands of inexperienced workmen, its ready adaptability for all power purposes, and the comparative freedom from injury to the machines worked by it in damp or wet pits, are further points of consequence. On the other hand, the greater efficiency of electricity, and the simplicity and lower cost with which it can be conveyed from the surface to the face, has led to its increased introduction for power purposes. For coal-cutting its use is extending very rapidly at the present time.

"*Compressed-Air Cutters.*—Machines driven by air are generally subject to a greater amount of vibration than those which are electrically driven. This renders it most desirable to have the machines frequently examined and small repairs constantly attended to, as, otherwise, the machine is apt to get into a bad state of repair, necessitating its withdrawal from the pit for complete repair and renovation. It is a desirable plan to keep spare machines, and to have each machine withdrawn after it has been in use for a certain time for a thorough overhaul. This is generally done on the surface, though in one instance an underground workshop has been established in order to avoid the expense of removing the machines from the workings. It is a material point to have the air freed from moisture, so as to avoid the mist which is otherwise caused by the exhaust, and for this purpose underground air-receivers are very beneficial. The face connections or hoses in use with compressed-air machines are heavy and awkward to manipulate. Their first cost is high, as well as the upkeep, as they are very liable to be cut and injured when drawn along the face, and spare lengths should always be kept in readiness for this reason. There are several descriptions of hose is use; and, probably, under ordinary circumstances, the ordinary indiarubber hose, marlin-wrapped, gives the most economical result.

"*Electric Cutters.*—The conditions in which coal-cutting machines have frequently to work are a peculiarly severe test of the construction of continuous-current motors. The heavy vibration, the great and sudden variations of load, coal-dust getting into the coils, moisture damaging the insulation, and the confined space which limits their size are all inimical to their constitution. Yet, it must be allowed, in face of the good results which in many cases they are giving, that the difficulties have been overcome to a large extent by increasing the capacity of the motor and strengthening its construction. Perhaps the chief trouble is the liability to overheating. As is well known, a current passing along a conductor generates heat, which is proportional to the square of the current multiplied by the resistance. This resistance increases with the rise in temperature, and even a small rise in temperature has a damaging effect on the insulating material and reduces its insulating power. The vibration and the presence of coal dust or of moisture also tend to break down the insulation of the coils of the armature. When a heavy strain is put upon a series-wound continuous-current machine, as frequently happens from the presence of pyrites or ironstone nodules in the stratum cut, or from coal or other material falling on the disc, an increased rush of current flows through the motor. If this continues for more than a few minutes, the insulation of the armature coils will be destroyed owing to overheating, and the machine will break down. This is by no means a rare occurrence in the early trials of electric disc machines, owing to the ignorance and inexperience of the attendants. To avoid it needs the close attention and ready judgment of the man in charge to switch off the current at the right moment. Bar and chain machines are not likely to become jammed, they consume less power, and therefore are not so liable to break down in this way. In view of the trouble arising from overheating, it is wiser not to let an electric coal-cutter run continuously for a long time without a stop. It works better when kept cool, but in practice stoppages are generally quite frequent enough.

"*Three-Phase Current.*—Three-phase induction motors have been applied successfully to coal-cutters, both of the disc and bar types. An experience of more than a year at Acton Hall Colliery, where they were first applied for this purpose, goes to show that they are practically free from this liability to break down. They have given great satisfaction there, and are preferred to continuous-current machines. The difficulty of their low starting torque has been overcome by a simple mechanical contrivance, which allows the motor to make a few revolutions before engaging the disc or bar. No commutator or sliding contacts are needed. A reversing switch is attached to the machine, and it can be reversed from full speed in one direction to full speed in the other without shutting off the current. The motor slows down, and then starts off in the opposite direction. During their considerable experience at Acton Hall Collieries they have never yet blown a fuse, though disc machines frequently have been stopped suddenly by coal falling on the disc. Three-phase motors occupy more height, which is a disadvantage in low seams. Electric cutters, owing to the rotary motion in place of the reciprocating, are not subject to such heavy mechanical strains as compressed-air machines. They require, however, to be constantly examined, and, with the cables, carefully tested and kept in order, as otherwise the efficiency of the plant will rapidly diminish. More skill and attention is undoubtedly required than is the case with compressed air. It is of the greatest importance that electric plant should be of a high class, both as regards material and workmanship, and that there should be no cheeseparing about an installation. A properly-constructed plant will give satisfaction, but an inefficient one probably gives more trouble than anything that can be put into a colliery, and it is the worst form of false economy. With electric cutters the face connections or trading cables are handier than the compressed-air hoses, but require to be properly protected. A twin cable appears to be the best, and this may be taped and armoured outside, or may be covered with leather or placed in an indiarubber pipe.

"As regards capital expenditure, there does not appear to be much difference between the first cost of a coal-cutting plant to be worked by compressed air and that of one to be electrically driven. From careful estimates of a first-class plant of either sort, consisting of generating plant complete, and the necessary cutters and their accessories (including two spare machines, without pipes or cables) suitable for a pit at which it is desired to run 10 machines, the cost per machine works out at about £1,000 in the case of compressed-air and £1,100 in that of electrically-driven machines. Electric machines are more expensive than compressed-air machines, the large ones costing about £350 to £450 each as against about £250 for compressed-air machines. The cost of pipes or cables is, of course, dependent on the depth and distance inby. Pipes are more expensive than cables, and, consequently, the greater the distance, the greater the saving in first cost under this head by the use of the latter, though probably the depreciation is considerably heavier. The estimated cost of pipes or cables for a plant of the dimensions named

Digitized by Google

above, including all face connections, works out at about £270 per machine for pipes and about £200 for cables, assuming that the depth of the shaft is 600ft. and that the distance from it to the workings is 4,200ft. With plant of increased capacity, the cost per machine would naturally be modified somewhat."

With the details of labour in connection with the machines we do not propose to deal, but in the paragraph relating to the cost of working per ton some figures are given to show that when electrical machines were first adopted high expense was incurred in consequence of armatures being burnt out. This cost in one of the collieries visited was as high as 1s. 2½d. per ton, but this was largely due to unsuitable plant. The committee's conclusion is that 7d. per ton on the average leaves some margin on the right side. As regards the increased production per man, a round average figure may be said to be three tons per shift with hand working and four tons when machines are employed. In other words, for an output of 1,000 tons 333 men are required with hand huing, as against 250 with machines. There is besides this a further gain in the concentration of the workings due to the increased output from a given face, requiring less length of road and less off-hand labour.

ELECTRIC TRANSMISSION DEVELOPMENTS IN NEW ZEALAND.

Through the courtesy of Mr. R. C. White, who is the engineer-in-charge of the Government electricity works at Rotorua, N.Z., we are able to give the following interesting information about electrical development in that district. Some of our readers may not know that the Government of New Zealand has a department devoted to tourists and health resorts, and has erected a sanatorium near the hot springs at Rotorua, which are noted for their medicinal properties in connection with the cure of rheumatism and kindred ailments. In order to supply the sanatorium and other houses in the district, electrical energy is being transmitted from the Okere Falls, 13 miles away. The curves we are able to give herewith clearly show the output and the type of load which this interesting little transmission has to cope with. It will be seen from Fig. 1 that on April 9 this year a maximum output of 85 kw. was required. The regulation is effected in such

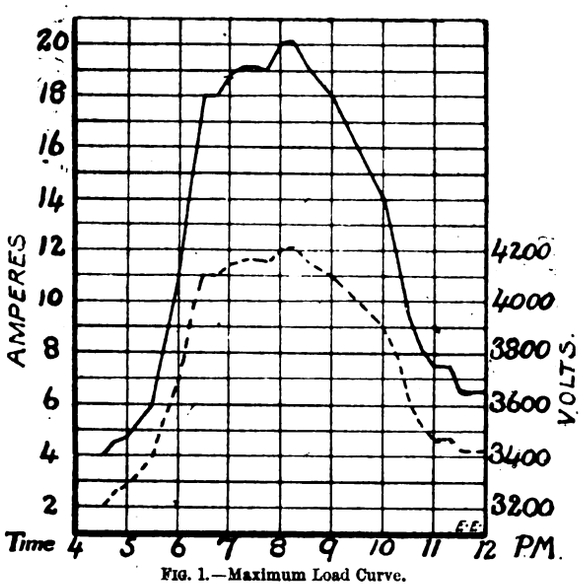

FIG. 1.—Maximum Load Curve.

a way as to keep a constant E.M.F. of 3,000 volts at the Rotorua end of the transmission line. In order to do this with a load of 85 kw., it will be seen that at the transmission end 4,200 volts are required. This means a loss in the line of no less than 1,200 volts. In view, however, of the cheap and practically unlimited power at the Okere Falls, this loss is quite permissible for the present. The minimum load in the current year occurred on Feb. 1 (Fig. 2), when the maximum only reached 40 kw. As is to be expected in an installation of this kind, there is clear evidence that the doctors insist on the patients going to bed early. Thus it will be seen that the maximum load occurs at 8 p.m., and after that time the load rapidly falls away. We understand that the plant is shortly to be extended very considerably, owing to the fact that a new sanatorium is being erected, which will involve much more generating machinery. The good work which has been done in this district with the transmission line of 13 miles is merely the forerunner of large transmission schemes in New Zealand, which will most likely be under the superintendence of the Government. An example of this, which has recently been referred to in our columns, is that of the Huka Falls, where

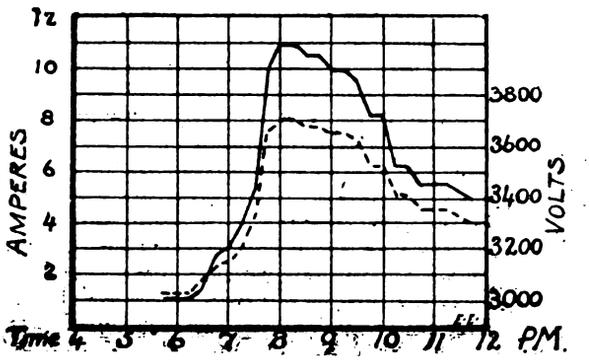

FIG. 2.—Minimum Load Curve.

very large water power is available. It is suggested that in this case sufficient electrical energy should be obtained to work all the trains on the North Island Trunk Railway from Auckland to Wellington. The Minister for Public Works, in answer to a question in the Legislative Assembly, stated that the Government had secured the services of an expert with great experience in America to advise them in the matter. The scheme would involve a transmission of over 200 miles. It is worthy of note that the New Zealand Government is so public spirited as to take the lead in the development of the country's unbounded natural resources.

APPOINTMENTS VACANT.

Junior Engineer, Dundee Town Council.

Working Electrical Engineer. See advertisement.

Armature Winders, Manchester. See advertisement.

Shift Engineer, £100 per annum. See advertisement.

Shift Engineer, Taunton Corporation, £100, 28th inst.

Station Superintendent, Motherwell Electricity Works, £117, Oct. 2.

Canvasser for a London electricity supply company. See advertisement.

Chief Tramways Officer, London County Council, £1,500, 28th inst.

Assistant Demonstrator, City and Guilds of London Institute. See advertisement.

Inspector of Apparatus, British Thomson-Houston Company. See advertisement.

Assistant, meter and testing department, National Electric Supply Company. See advertisement.

Motor and Meter Inspector, supply station in North of England 30s. per week. See advertisement.

Clerk of Works during the construction of tramways and road widenings, Aston Manor Urban District Council, £3 per week. Duties to commence early in October, and duration of engagement for about 12 months. Applications, stating age and experience, to Mr. Robert Green, 37, Waterloo-street, Birmingham, by 26th inst.

Superintendent of Electric Lighting, etc. The Crown Agents for the Colonies will receive applications for the appointments of (1) superintendent of electric lighting, and (2) assistant electrical engineer, under the Public Works Department of the colony of Lagos. Salaries £400 and £300 per annum respectively, appointments for two years' service in the colony. Four months' leave on full pay in this country at the end of each 12 months' continuous service if returning to the colony, and two months if not returning to the colony. Half salary on the first voyage out, but on subsequent voyages full salary will be paid. Applications by letter, stating age and experience, and accompanied by copies of not more than three recent testimonials, will be received by the Crown Agents for the Colonies, Downing-street, London, S.W., up to Oct. 7. The following reference should be quoted on the top left-hand corner of letter of application, M.1,751.

Secretaries and Managers of Companies are invited to furnish Notices of Meetings, Issues of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS WANTED will be charged at three words for One Penny (prepaid and net), with a minimum charge of Sixpence.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office on the following terms:*

	3 months.	6 months.	12 months.
United Kingdom	3s. 3d.	— 6s. 6d.	— 13s. 0d.
Other Places	5s. 6d.	— 10s. 6d.	— 21s. 0d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

Bound Volumes of "THE ELECTRICAL ENGINEER," *containing half-year's copies, bound in Dark-Blue Cloth, Gold Lettered, price 8s. 6d. New Volume, January to July, 1903, now ready.*

THE WINTER SESSION.

Men and societies will now be settling down for the winter's work. The interval has been a busy, an interesting, if not an eventful one. The rapid progress in various directions, not only in electrical matters but in other engineering ways, has resulted in the multiplication of societies, each one of which pays particular attention to a special branch of the industry or science it is designed to represent. We are not alarmed at this state of things, though much has been said detrimentally about the number of institutions. There is one phase of the question, however, about which we should like to offer a suggestion. While it seems necessary for the better consideration of details that a number of societies should exist, there are certain fundamental questions relating to all. The British Association has of recent years introduced a system for the discussion of common questions which we think might with advantage be extended, and followed by many societies dealing with different phases of the same subject. It is somewhat invidious to refer to particular societies, but as no reflection is intended, there can be no harm done. It is quite conceivable that an interesting paper could be contributed which would be equally attractive to the Institution, to the Physical Society, to the Faraday Society, and to similar societies—not forgetting to mention the parent of all, the Royal. Men can only devote a certain time to society meetings, and a common meeting with a lapse of an ordinary meeting might enable a larger number to take part in the proceedings. There is far too much exclusiveness in some of our institutions. They are carried out simply as mutual admiration societies, with a curt stand off addressed to those who will not fall down and worship a man whom they are told they ought to worship. Some of them are intensely cliquish, and run more for the benefit of a few active spirits than for anything else. Just as travel broadens the mind of the traveller, so the bringing together of various societies to discuss a common question would tend to prove that no one society contains all the talent of the kingdom We badly want variety, even crass heterodoxy. It is too often only necessary to glance round the faces at a meeting to be able to foretell the names of the speakers, and most frequently it is easy to foretell what they will say. A man who has something to say, and says it in a few words, is a *rara avis* (if a man can be compared to a bird), while the man who has nothing to say, and hides his dearth of such information under a mass of verbiage, is but too apparent.

Another suggestion as to very important questions not coming within the purview of existing societies. Take three questions at the present time important, but not to be dealt with by existing societies in the manner they ought to be dealt with: municipal trading, depreciation in municipal work, and the fiscal question as it affects the electrical industry. These subjects are dealt with in societies and institutions having definite aims and objects, but opposing interests have seldom or never been brought together to try and find out the real points of difference and the points of agreement. Is it impossible to try to get at the truth rather than at some conclusion which seems to assist the party that comes to that conclusion? To give an example outside of electrical matters—some men have written of a certain branch of the glass trade as having been killed by free trade; others give chapter and verse that the trade has been killed by the stupidity of trades unionism. We have at various times given details of electrical apparatus obtained from foreign sources. The value of this appears in the imports, yet the importation has no more to do with free trade or pro-

Digitized by Google

tection than we have with the government of Mars. Surely, then, it is necessary that men who know the inner details of business should discuss questions affecting a large industry, rather than allow questionable conclusions to be deduced by those unacquainted with the realities of the question. How and when now can such subjects be considered?

CORRESPONDENCE.

Justice needs that both be heard."

INTERMEDIATE SWITCHES AND WIRING.

SIR,—Having been greatly interested in the development of two-way and intermediate wiring from their earliest days, it is gratifying to notice how general the adoption of the latter is also becoming, as your "Questions and Answers" columns of Sept. 11, 1904, show (Answer 610, pp. 399-401).

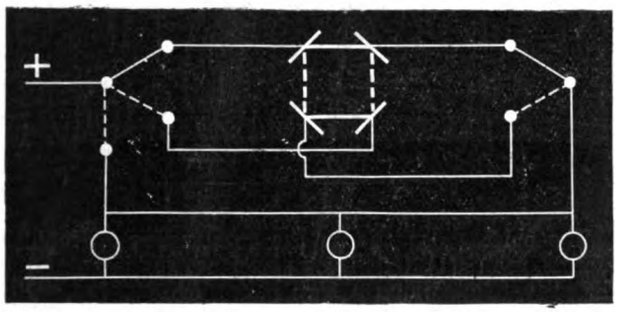

FIG. 1.

I do not think it is generally known, but to Mr. W. H Massey, M.I.C.E., we are indebted for this simple system, where intermediate switches are used to give alternate paths to the current and allow perfect control at every point (Patent No. 16,091, 1891), the first adaptation being

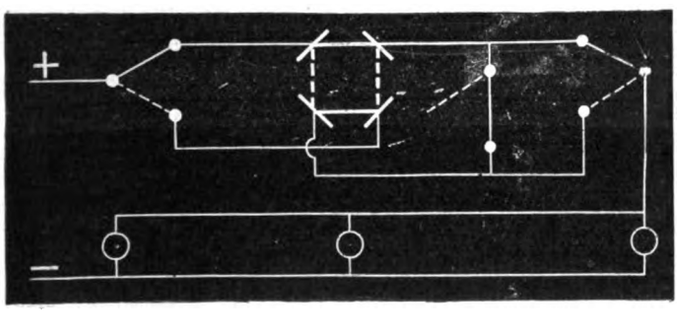

FIG. 2.

made in the autumn of 1891 at the house of H. M. Brunel, Esq. Mr. Massey has done much to advocate the use of this ingenious arrangement, and it now appears as if a general adoption will result.

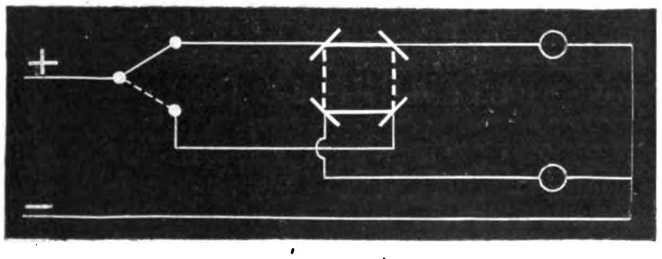

FIG. 3.

A few variations on the original idea may be of interest, and prove at times useful to adopt. Fig. 1 shows how a three-way switch is used at one end in place of the usual two-way switch; this arrangement enables a janitor in flats to cut out of circuit all other switches at times when it is undesirable that the lamps should be turned off. Fig. 2 shows that by the insertion of a simple "master" switch between the two + wires *at any point*, control of the lamps is prevented. Fig. 3 shows a two-way switch used for turning on either of two lamps, or of two groups of lamps; it will be seen that any number of intermediate switches may be fixed in series with such and allow control from other points.

Some mention has been made of the disadvantage of having to use two types of switches (the thumb-key and tumbler) on the same circuit, as the tumbler movement could not be obtained adapted for "intermediate" use, or at the best, the necessity of coupling two tumbler switches together, which means less simple connections and an ugly fitting. I have a tumbler switch movement constructed in accordance with my patent No. 131, 1901, to form an intermediate switch, the article being of standard size except for a slightly thickened base. Fig. 4 shows the circuit connections where only tumbler type switches are used.

While on the subject of intermediate wiring, it may be of interest to your readers to study the patent specification

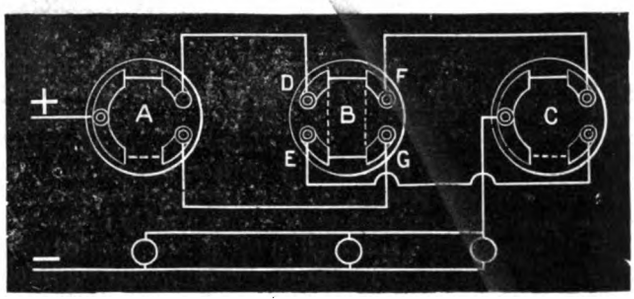

FIG. 4.

of C. A. Allison, No. 6,606, 1894, which describes a different plan for accomplishing a similar object to that shown in Fig. 4.—Yours, etc., A. P. LUNDBERG.

London, N., Sept. 17, 1903.

PRIORITY IN OIL-BREAK SWITCHES.

SIR,—In the paper read before the British Association recently by Mr. W. B. Woodhouse, it is said "that the first oil-break switch to be put to practical use was at the Paderno power station in 1897," and that "this was designed by Messrs. Brown, Boverie, and Co."

This statement should have been qualified to apply to the Continent only, because it is well known that oil-break switches were used in this country earlier than 1897. This company designed oil-break switches in 1894. The first large switchgear made which contained oil-break switches was installed by us at the City of London Electric Lighting Company's works at Bankside. The switches were erected and tested in 1895, and the complete equipment was put into constant use in the following year, and it has been giving—as far as we are aware—satisfactory results ever since. Originally the gear consisted of 60 panels, each suitable for a maximum capacity of about 750 kw. at 2,000 volts, but has since been extended to about 80 panels of the same design.

It may also interest your readers to be reminded that Mr. Ferranti's patent for "electric switches in which the contacts are immersed in oil or other insulating fluid upon breaking" was applied for in 1895.—Yours, etc.,

FERRANTI LIMITED.

Hollinwood, Lancs., Sept. 22, 1903.

ON SINGLE-PHASE REPULSION MOTORS.*

BY WILLIAM CRAMP, A.M.I.E.E.

It is a matter of common knowledge that if it were possible to construct a single-phase alternate-current motor having the characteristics of a direct-current series motor, and no serious drawback, it would find a very extensive

* Paper read before the British Association, Southport meeting.

Digitized by Google

application, on account of its extreme suitability for the transmission of power, especially in connection with railway work on long lines. There are many forms of single-phase induction motor on the market, some of which are, for certain purposes, very useful. Yet in spite of these, the single-phase motor is avoided wherever possible, as is clear from the many costly alterations which are being carried out in this country. It is only necessary to mention a few examples of this. In Croydon a direct-current plant has been laid down for the centre of the town, solely to provide for motors, in addition to the already existing alternating supply. The City of London Electric Lighting Company are slowly replacing alternating by direct current, for similar reasons. The towns of Coventry and Sheffield are introducing two-phase in place of the existing single-phase system. No doubt, much of this will be changed if the Baltimore and Annapolis Railway is successful, since that will demonstrate the existence of single-phase motors comparable to the direct-current series motor, and the extreme simplicity and flexibility of the single-phase system will again recommend its adoption in cases where three-phase plant is now in contemplation.

At present there is a choice of three types of motors on single-phase systems.

1. *The Synchronous Motor.*—The disadvantages of this form, where starting and stopping is frequently necessary, are sufficiently obvious

2. *The Asynchronous Induction Motor.*—The disadvantages of this motor are that special devices, always cumbrous and often very expensive, must be employed to start it up, and even then a current usually considerably in excess of the full-load current is needed to run it up to speed under load—often a grave objection on lighting circuits. Moreover, even under favourable conditions, the power factor is poor, the efficiency not high, the possibilities of varying the speed almost nil.

3. *The Series Alternate-Current Motor.*—This moter bids fair to rival the previous forms for general application, and will, as we have said, be thoroughly tested on the Baltimore and Annapolis Railway. Its disadvantages are that the frequency at which it is most successful is very low, thus rendering it inadmissible on lighting circuits, while its power factor tends to decrease with load, and pressure difficulties at the commutators are almost unavoidable.

The only other type at present practicable is the repulsion motor. For several years past I have been working to ascertain the lines on which really efficient and satisfactory motors of this type might be designed, and I now believe that repulsion motors may be built, up to at least 20 h.p., which will compare favourably with any type of motor at present in use. In its simplest form the repulsion motor consists of a laminated electromagnet or stator excited from the single-phase mains, and an armature or rotor wound almost exactly like the armature of a direct-current machine, and fitted with a similar commutator. Brushes rubbing on this commutator are set at a particular angle and short-circuited. The alternating flux set up by the stator induces in the coils of the rotor currents in such directions that the coils carrying them tend to move out of the inducing field. The action is exactly the same as that shown by Prof. Elihu Thomson to exist when a plain copper ring is brought into the field of a solenoid excited by an alternating current.

Figs. 1 and 2 show clearly the two main forms of repulsion motor. In Fig. 1 the angle θ is usually 45deg. or less. This type has the following peculiarities: (*a*) the E.M.F. of a quarter of the rotor opposes that of the other three quarters, leaving half the rotor for useful E.M.F.; (*b*) the rotor current passes through all the coils, whether in a useful position or not, thereby increasing the $C^2 R$ loss; (*c*) a quarter of the rotor gives a torque opposing rotation; (*d*) individual coils short-circuited by the brushes are constantly giving a torque opposed to rotation, and causing difficulties with commutation. These disadvantages led me to construct repulsion motors on the lines of Fig. 2; and it is partly due to the adoption of this form that I have succeeded in obtaining satisfactory commutation. The difficulties of construction, chief among which is commutation, have led most writers to speak of repulsion motors with much distrust. Thus Elihu Thomson, whose patent of 1889 covers the whole principle of repulsion motors, refers to them as capable of giving out considerable power, "though with what economy is unknown." Prof. Jackson condemns them as "bulky, expensive, and inefficient," though he adduces no evidence in favour of this verdict. Mr. Steinmetz writes "they have the disadvantage of using only part of the rotor," but as recently as December, 1902, he said that he believed better results were to be obtained from them than from series alternate motors. To show how very misleading are these statements, I here add: (1) That Mr. Hobart proposes using only 50 per cent. of the armature for his recent direct-current machines. (2) If the coils of the rotor are only half of them used at any given instant, it is obviously possible to work at a higher current density. In one of my experimental motors I have had eight amperes through No. 21 wire without serious heating. (3) In such alternators as the Mordey-Victoria, only half the armature is ever really active at one time.

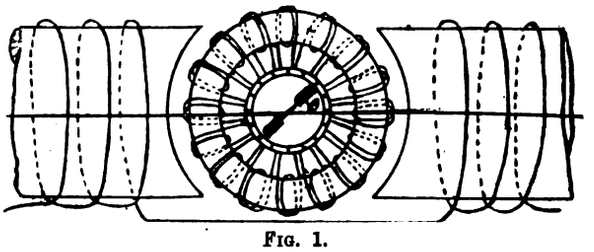

FIG. 1.

The chief difficulties in the construction of repulsion motors are: (1) liability to vicious sparking and (2) difficulty in obtaining a high power factor. In the first form of repulsion motor which I tried I found that the spark was almost as great on closing the coil as on opening it. In order to investigate this, I had some experiments carried out on the opening and closing of circuits, of which I now relate briefly the results. With an inductive circuit there was less tendency to spark on the make than with a non-inductive circuit, and there was much less tendency to spark on the make with copper than with carbon contacts. I find, on the whole, that to avoid sparking on the make, a good, firm, clean, low-resistance contact is adequate. For this reason I have so far used copper brushes in the motor, but, despite this, the choice between carbon or copper has to be decided by the consideration of the whole of the circumstances, which would be too long to discuss now. With copper brushes I have been able to get absolutely sparkless commutation, working from

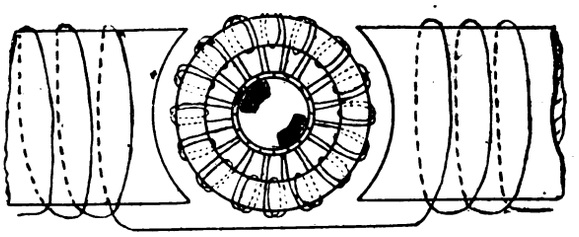

FIG. 2.

nothing to full load, on a motor whose design was in other respects distinctly faulty. These results refer more particularly to motors of the class represented by Fig. 2, whose only disadvantage is the long arc of brush contact, entailing corresponding friction. Having by copper brushes provided for closing the circuit sparklessly, I was enabled to obtain sparkless opening by means of the same principles that are employed in what is known as "resistance commutation"—that is, providing a sufficient interpolar space to enable each rotor coil to pass entirely outside the magnetic field, so that the current can die down before the opening of the circuit. It is obvious that a form of commutation might be employed corresponding to what in dynamo design I call "E.M.F. commutation" (a term which explains itself); or, better still, a combination of E.M.F. and resistance commutation, and as the output of the motor undoubtedly increases with pole width, it might pay to use one of these modifications, on which point, indeed, I am at present experimenting. In considering the actual

Digitized by Google

design of a repulsion motor, the first object is to decide which form of commutation you are going to rely upon. Having settled this, the form of stator is practically fixed, for if resistance commutation is to be relied on entirely, the stator must have distinct poles—by this I mean that there must be considerable air-space left between one polar winding and the next, as in the direct-current machine. On the other hand, if E.M.F. commutation be used, the stator may be built exactly like that of an ordinary single-phase motor. I have tried both forms, and find that while both may be rendered sparkless between certain limits, the former gives good commutation over a wider range, while the latter gives better starting torque and better power factor. But I would insist on the fact that every form of repulsion motor may be rendered sparkless if the design of the rotor winding is properly considered. Thus, what has been hitherto the great disadvantage of the repulsion motor disappears.

We therefore proceed to consider the design of the rotor winding. We may choose an arrangement such as that in Fig. 1, or a modification of Fig. 2. The salient differences between these two forms are: (1) in Fig. 1 all the short-circuited coils are in series, while in Fig. 2 they are in parallel; (2) in Fig. 1 the rotor current always passes through the whole of the rotor coils, whether active or useless; in Fig. 2 this is obviously not the case. If the rotor winding has to carry a large current, Fig 2 is not very suitable on account of the fact of the large heating that takes place at the commutator, and the large proportion which brush resistance bears to the resistance of the coil lying between any given pair of segments. I have already

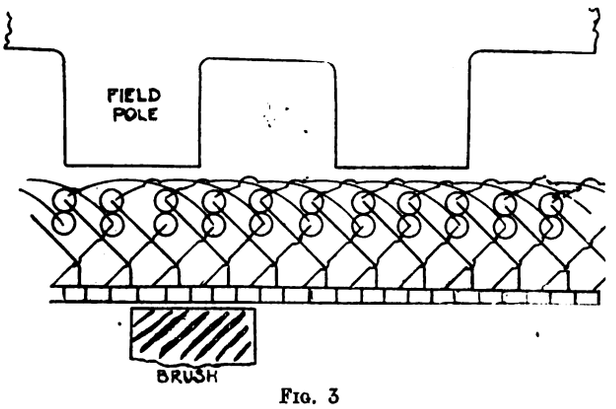

FIG. 3

stated, under the head of "Commutation," other reasons for selecting windings of the type of Fig. 2, but I ought to add that recent experiments with windings of the type of Fig. 1 impress me very favourably, and all motors at present under construction are of this type. In actual experiment with windings like Fig. 2, I have found that if the rotor is of the closed-coil type, as shown, besides those coils actually short-circuited, there are other closed circuits carrying useless, or even harmful currents. Hence, in the particular motor on which most of these experiments were made, the winding has been altered to that of Fig. 3, thus practically converting the rotor into an open-coil armature, with two coils in parallel.

These considerations determine the type of rotor winding, and we now pass to the discussion of the E.M.F., current, torque, etc., taking first the case of a bipolar motor with a single coil, as in Fig. 4A. This diagram is really a simple case of Fig. 2. If the pole arc is 50 per cent. of the pole-pitch, and equal to the width of the coil, and the distribution of magnetic flux radially around this pole arc is sinusoidal, then the E.M.F. set up in the coil is a pure sine wave. If, however, the flux is distributed *uniformly* radially over the pole arc (as is more probable in an actual machine), the lines enclosed by the coil when the field is constant are as represented in Fig. 4B. This is a sine wave with some odd harmonics, which are of small importance in the present case; the third harmonic, which is the largest, has an amplitude of only 1/9, the fundamental. I shall assume, then, for present purposes, that both the time variation of the main flux and the time variation of the area of the coil with respect to the total flux are both sine functions. We then have, if number of turns on the stator winding $= t_1$, number of active turns on the rotor $= t_2$, maximum magnetic flux per pole $= F$, speed of motor in revolutions per second $= n$, periodicity of stator current in periods per second $= f$, R.M.S. primary E.M.F. $= e_1$, R.M.S. secondary E.M.F. $= e_2$. Then it is found that

$$e_2 = \frac{e_1}{\sqrt{2}} \frac{t_2}{t_1} \sqrt{1. + \left(\frac{n}{f}\right)^2}$$

which means that the secondary E.M.F. may be represented by the resultant of two lines at right angles, as shown in the phase diagram (Fig. 5).

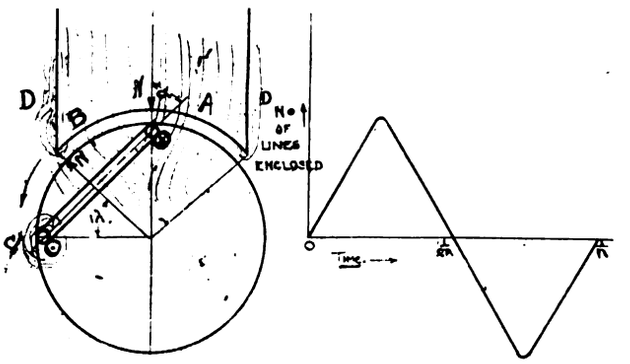

FIG 4.

Passing on to the equations for current, we have, upon closing the circuit when one side of the coil is just coming into the field, a current made up of two terms—(A) the exponential term, (B) the ordinary sine wave. The term (A), which may usually be neglected in other alternating-current apparatus, is often, in the case of the repulsion motor, of great importance. It is extremely difficult to show the value of this term in any phase diagram, but its general effect is to shift the rotor current slightly forward in phase, and to cause the torque of the rotor to sink to zero at a lower speed. The cases in which it is of greatest importance are those of the type of Fig. 2, in which the number of turns per coil is large. I found its effects to be very strongly marked in the first two motors I made; but I do not anticipate that in future designs its effect will be so marked, for two reasons: first, because I now aim at few turns per rotor coil; and, secondly, because I use a greater number of commutator segments. Coming now to term (B), I think it is easier to

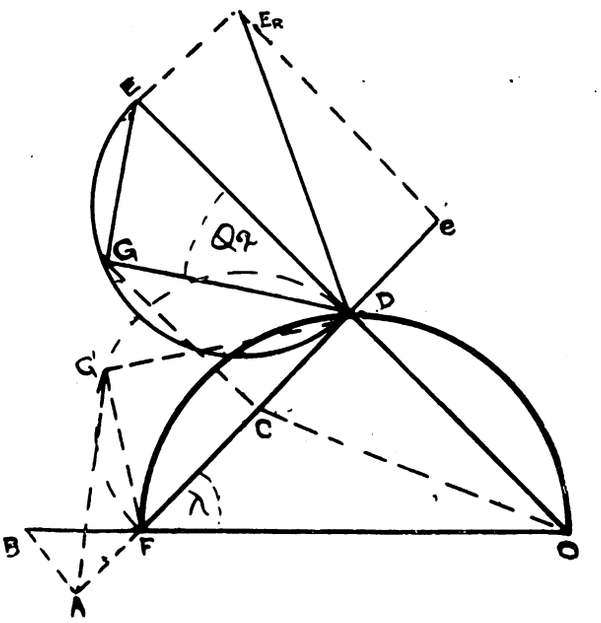

FIG. 5.

consider the action of the motor from the standpoint of the Heyland diagram. In Fig. 6 we have a representation of the transformer diagram. Figs. 4 and 6 are lettered alike. S is the stator, R the rotor. Let the flux at T T be represented by O F (Fig. 5).

Digitized by Google

Now, we may resolve the field O F in two directions in space—viz., along the line of the brushes and at right angles thereto. F D and D O will represent these components, the point D lying upon a semi-circle, as shown. The angle D F O is that corresponding to λ in Fig. 4. D F now represents the field which vibrates through the rotor coil, and D E, at right angles and proportional to it, must represent *in time* the E M.F. generated in the rotor coils. (It is better to keep time and space separate by arranging all quantities in *phase in time* in one plane. Thus D E would be drawn in a plane at right angles to that containing D F O, as is done in the author's model.) The E.M.F., D E, may be resolved into two components at right angles in time D G, G E. Of these two, G D is proportional to the C R drop in the rotor coil, and hence to scale (with constant rotor resistance) represents the magnitude and phase of the rotor current. G E represents that component of the rotor current tending to demagnetise the stator. The angle ϕ_2 is the angle of lag of the secondary or rotor current. As ϕ_2 increases, the rotor C R drop D G decreases and the rotor demagnetising component increases till E G = E D, when the rotor current is zero and the field F D is balanced. Now, since D E is proportional to D F, it may be drawn of the same length. Then the semi-circle D G E may be applied to the line D F, so that E falls on F D G, and E G becomes F G^1, and shows the way in which D F becomes gradually balanced. The angle G^1 D F then = G D E = ϕ_2. Now, the component of D G in phase with D F or D O is the projection of D G on D F = D C = D G sin ϕ_2. This component multiplied by D O is proportional to the torque of the motor—*i e*, the torque varies as the area of the triangle D C O.

We have rotor current $\propto$ D G $\propto$ D E cos ϕ_2;

D E $\propto$ D F = O F cos O F D = O F cos λ;

D O = F O sin λ;

D C = D G sin ϕ_2.

Hence torque at starting = D C $\times$ D O;

= D E sin ϕ_2 cos $\phi_2 \times$ O F sin λ;

= O F . O F . sin ϕ_2 cos ϕ_2 sin λ cos λ;

which is a maximum when $\left\{\begin{matrix}\sin\lambda=\cos\lambda\\ \sin\phi_2=\cos\phi_2\end{matrix}\right\} = \frac{1}{\sqrt{2}}$—*i.e*,

when α and ϕ_2 = 45deg.

Now, O F $\propto$ primary voltage (nearly). Hence the starting torque is proportional to O F^2—*i.e.*, to the primary voltage^2.

These are the starting conditions.

Running Conditions.—Directly the starting torque is large enough the rotor begins to revolve, the coil F (Fig. 4) tending to set itself so that it encloses a minimum of the magnetic lines issuing from the stator. Thus motion takes place in the direction of the arrow in Fig. 4; and this must be due to the fact that the current sets up a field in the rotor coils which is on the whole of opposing—*i.e.*, identical—polarity to that existing in the stator. Thus, if at a particular instant (in Fig. 4) the polarity of the stator is north, as marked, the polarity of the rotor field, due to the lagging rotor current, must at the same instant be north. At this particular instant the lagging rotor current must be in the direction shown by the cross (+) and dot in Fig. 4. By Lenz's law the E M.F. set up by rotation must oppose this current. Therefore, directly the rotor begins to revolve, the rotor lagging current is reduced, or, in other words, the coefficient of self-induction of the rotor coil is virtually diminished. Suppose, now, the rotor is running, then the coil shown in Fig. 4, immediately it moves, would have its place taken by the one next it, and thus, although the rotor revolves, we may, as it were, speak of an "equivalent stationary coil," whose axis is settled by the diameter upon which the brushes are set. Considering now the coil shown in Fig. 4 as representing this equivalent stationary coil, we see that its coefficient of self-induction may be altered to a certain extent by moving it round in the direction of rotation. In this way, however much the phase of the rotor current may be altered by the E.M.F. due to rotation, the original conditions may be reproduced by moving the brushes in the direction of rotation. Theoretically, this may be carried on till the axis of the coil is at right angles to the axis of the field, when the speed of the rotor is infinite. Naturally, in practice there is a limit, depending upon the particular form of stator and the torque necessary to overcome the friction of the rotor bearings, etc.

In order to show this E.M.F. due to rotation in Fig. 5, we remember that it is really produced by the field D O, and, therefore, will be at right angles to D O in space. Thus it may be represented by D *e*, and its effect is obviously to reduce the secondary lagging current, thus reducing the primary lagging component and the total primary current. With increasing speed, then, the point *g* will tend to travel along its semi-circle. The value of the component

$$\text{D E} = \frac{e_1}{\sqrt{2}}\frac{t_2}{t_1}, \text{ whilst D } e = \frac{e_1}{\sqrt{2}}\frac{t_2}{t_1}\cdot\frac{n}{f}.$$

Thus at synchronism D *e* = D E, and if the motor started with maximum torque the point *g* will have arrived at E, when the motor arrives at synchronous speed.

The above results are only approximately correct, for the following reasons. We have assumed conditions of constant field which do not exist exactly in ordinary conditions. Again, we have assumed that the current-conductor distribution around the rotor is sinusoidal, which is not true, and that the number of conductors acted upon by the field D O is the same as that under the influence of the field D F. Later I hope to have an opportunity of showing how each of these peculiarities affects the phase diagrams already given. For the present it is important to note that the machine will generate if revolved in the direction opposite to the arrow in Fig. 4.

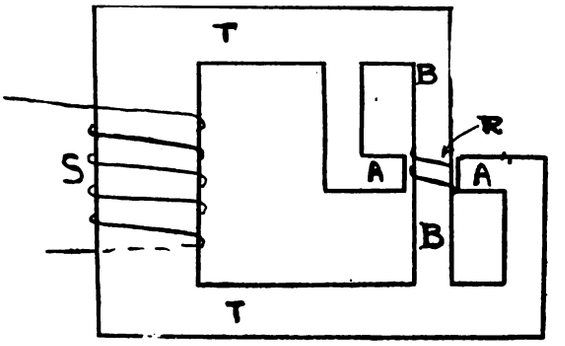

FIG. 6.

Since the law of the diagram is so simple, a model may easily be constructed, ruled by the fact that O F is of constant length, and the point D moves along a semi-circle. From this model the values of primary and secondary current, torque, and power factor may readily be deduced, and the following peculiarities may be noted:

1. The *torque* depends on the relative phases of stator and rotor currents, and at starting it is a maximum when the power factor is about 60 per cent. At any speed the torque will always be a maximum with about this power factor, but in order to keep this maximum torque the brushes would have to be gradually moved in the direction of rotation as the speed rose. In the case of small motors, I should say that there is no reason at all why the brushes should not be moved forward, either automatically or by hand in this way, since, as already shown, sparking difficulties may be completely overcome.

2. *Power Factor.*—If maximum torque is required of the motor at starting, and the brushes are to be kept fixed, it follows that the power factor can never exceed 70 per cent. This at first sight appears a serious drawback, but in actual practice there are many cases where it will be no disadvantage at all. Take, for instance, a small printing establishment, or a tramway system of no great length. The disadvantages of the lagging current are two-fold: (1) C^2 R loss in the line—of small importance, as we have supposed the line short; (2) reduction of the voltage at the generating station by reaction upon the alternator fields, which is clearly counter-balanced by the fact that the power factor of such motors is a maximum at starting and gradually decreases as the stator current decreases while

Digitized by Google

running. Thus the actual value of the lagging current will not vary very seriously, and, so far as the engineer at the central station is concerned, should cause no trouble. In fact, the motor is in this respect in as good a position as a polyphase motor started with resistance in its rotor circuit, and in a far better position than any ordinary single-phase induction motor. In the case of large motors or long transmission lines, the power factor of the motor with maximum torque at high speeds may be very materially increased. Perhaps the best way of doing this is by means of slip-rings attached to the rotor windings, just as if it were a rotary converter. Resistances inserted between these slip-rings are gradually cut out as the speed rises, so that the motor finally acts as an induction motor, a device of mine incorporated in a repulsion motor arranged at the Central Technical College three years ago, and which I see from an article by Herr Schüler in the *Electrical Engineer* of Sept. 4 has recently been the subject of an English patent.
